$$\begin{aligned} \underbrace{E_{\text{in}} - E_{\text{out}}}_{\substack{\text{Net energy transfer} \\ \text{by heat, work, and mass}}} &= \underbrace{\Delta E_{\text{system}}}_{\substack{\text{Change in internal, kinetic,} \\ \text{potential, etc. energies}}} \\ Q_{\text{in}} - Q_{\text{b,out}} = \Delta U = mc_v \Delta T &= 0 \\ Q_{\text{in}} = Q_{\text{b,out}} &= 2.43 \text{ kJ} \end{aligned}$$

(b) The exergy destroyed during a process can be determined from an exergy balance, or directly from $X_{\text{destroyed}} = T_0 S_{\text{gen}}$. We will use the second approach since it is usually easier. But first we determine the entropy generation by

applying an entropy balance on an *extended system* (system + immediate surroundings), which includes the temperature gradient zone between the cylinder and the furnace so that the temperature at the boundary where heat

transfer occurs is $T_R = 1200 \text{ K}$. This way, the entropy generation associated with the heat transfer is included. Also, the entropy change of the argon gas can be determined from Q/T_{sys} since its temperature remains constant.

$$\begin{aligned} \underbrace{S_{\text{in}} - S_{\text{out}}}_{\substack{\text{Net entropy transfer} \\ \text{by heat and mass}}} + \underbrace{S_{\text{gen}}}_{\substack{\text{Entropy} \\ \text{generation}}} &= \underbrace{\Delta S_{\text{system}}}_{\substack{\text{Change} \\ \text{in entropy}}} \\ \frac{Q}{T_R} + S_{\text{gen}} &= \Delta S_{\text{sys}} = \frac{Q}{T_{\text{sys}}} \end{aligned}$$

Therefore,

$$S_{\text{gen}} = \frac{Q}{T_{\text{sys}}} - \frac{Q}{T_R} = \frac{2.43 \text{ kJ}}{400 \text{ K}} - \frac{2.43 \text{ kJ}}{1200 \text{ K}} = 0.00405 \text{ kJ/K}$$

and

$$X_{\text{dest}} = T_0 S_{\text{gen}} = (300 \text{ K})(0.00405 \text{ kJ/K}) = \mathbf{1.22 \text{ kJ}}$$

(c) The reversible work, which represents the maximum useful work that could be produced $W_{\text{rev,out}}$, can be determined from the exergy balance by setting the exergy destruction equal to zero,

$$\begin{aligned}
 \underbrace{X_{\text{in}} - X_{\text{out}}}_{\substack{\text{Net exergy transfer} \\ \text{by heat, work, and mass}}} - \underbrace{X_{\text{destroyed}}}_{\substack{\text{Exergy} \\ \text{destruction}}} \stackrel{\text{reversible}}{=} \underbrace{\Delta X_{\text{system}}}_{\substack{\text{Change} \\ \text{in exergy}}} \\
 \left(1 - \frac{T_0}{T_b}\right) Q - W_{\text{rev,out}} = X_2 - X_1 \\
 = (U_2 - U_1) + P_0(V_2 - V_1) - T_0(S_2 - S_1) \\
 = 0 + W_{\text{surr}} - T_0 \frac{Q}{T_{\text{sys}}}
 \end{aligned}$$

since $\Delta KE = \Delta PE = 0$ and $\Delta U = 0$ (the change in internal energy of an ideal gas is zero during an isothermal process), and $\Delta S_{\text{sys}} = Q/T_{\text{sys}}$ for isothermal processes in the absence of any irreversibilities. Then,

$$\begin{aligned}
 W_{\text{rev,out}} &= T_0 \frac{Q}{T_{\text{sys}}} - W_{\text{surr}} + \left(1 - \frac{T_0}{T_R}\right) Q \\
 &= (300 \text{ K}) \frac{2.43 \text{ kJ}}{400 \text{ K}} - (1 \text{ kJ}) + \left(1 - \frac{300 \text{ K}}{1200 \text{ K}}\right) (2.43 \text{ kJ}) \\
 &= \mathbf{2.65 \text{ kJ}}
 \end{aligned}$$

Therefore, the useful work output would be 2.65 kJ instead of 1.43 kJ if the process were executed in a totally reversible manner.

Alternative Approach The reversible work could also be determined by applying the basics only, without resorting to exergy balance. This is done by replacing the irreversible portions of the process by reversible ones that create the same effect on the system. The useful work output of this idealized process (between the actual end states) is the reversible work. The only irreversibility the actual process involves is the heat transfer between the system and the furnace through a finite temperature difference. This irreversibility can be eliminated by operating a reversible heat engine between the furnace at 1200 K and the surroundings at 300 K. When 2.43 kJ of heat is supplied to this heat engine, it produces a work output of

$$W_{\text{HE}} = \eta_{\text{rev}} Q_H = \left(1 - \frac{T_L}{T_H}\right) Q_H = \left(1 - \frac{300 \text{ K}}{1200 \text{ K}}\right) (2.43 \text{ kJ}) = 1.82 \text{ kJ}$$

The 2.43 kJ of heat that was transferred to the system from the source is now extracted from the surrounding air at 300 K by a reversible heat pump that requires a work input of

$$W_{\text{HP,in}} = \frac{Q_H}{\text{COP}_{\text{HP}}} = \frac{Q_H}{T_H / (T_H - T_L)} = \frac{2.43 \text{ kJ}}{(400 \text{ K}) / (400 - 300) \text{ K}} = 0.61 \text{ kJ}$$

Then the net work output of this reversible process (i.e., the reversible work) becomes

$$W_{\text{rev}} = W_u + W_{\text{HE}} - W_{\text{HP,in}} = 1.43 + 1.82 - 0.61 = 2.64 \text{ kJ}$$

which is practically identical to the result obtained before. Also, the exergy destroyed is the difference between the reversible work and the useful work, and is determined to be

$$X_{\text{dest}} = W_{\text{rev,out}} - W_{u,\text{out}} = 2.65 - 1.43 = 1.22 \text{ kJ}$$

which is identical to the result obtained before.

8-116 A heat engine operates between two constant-pressure cylinders filled with air at different temperatures. The maximum work that can be produced and the final temperatures of the cylinders are to be determined.

Assumptions Air is an ideal gas with constant specific heats at room temperature.

Properties The gas constant of air is $0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$ (Table A-1). The constant pressure specific heat of air at room temperature is $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ (Table A-2).

Analysis For maximum power production, the entropy generation must be zero. We take the two cylinders (the heat source and heat sink) and the heat engine as the system. Noting that the system involves no heat and mass transfer and that the entropy change for cyclic devices is zero, the entropy balance can be expressed as

$$\underbrace{S_{\text{in}} - S_{\text{out}}}_{\text{Net entropy transfer by heat and mass}} + \underbrace{S_{\text{gen}}}_{\text{Entropy generation}} \stackrel{\approx 0}{=} \underbrace{\Delta S_{\text{system}}}_{\text{Change in entropy}}$$

$$0 + S_{\text{gen}} \stackrel{\approx 0}{=} \Delta S_{\text{cylindersource}} + \Delta S_{\text{cylindersink}} + \Delta S_{\text{heat engine}} \stackrel{\approx 0}{=}$$

$$\Delta S_{\text{cylindersource}} + \Delta S_{\text{cylindersink}} = 0$$

$$\left(mc_p \ln \frac{T_2}{T_1} - mR \ln \frac{P_2}{P_1} \right)_{\text{source}} + 0 + \left(mc_p \ln \frac{T_2}{T_1} - mR \ln \frac{P_2}{P_1} \right)_{\text{sink}} = 0$$

$$\ln \frac{T_2}{T_{1A}} \frac{T_2}{T_{1B}} = 0 \longrightarrow T_2^2 = T_{1A} T_{1B}$$

where T_{1A} and T_{1B} are the initial temperatures of the source and the sink, respectively, and T_2 is the common final temperature. Therefore, the final temperature of the tanks for maximum power production is

$$T_2 = \sqrt{T_{1A} T_{1B}} = \sqrt{(900 \text{ K})(300 \text{ K})} = \mathbf{519.6 \text{ K}}$$

The energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ for the source and sink can be expressed as follows:

Source:

$$-Q_{\text{source,out}} + W_{b,\text{in}} = \Delta U \rightarrow Q_{\text{source,out}} = \Delta H = mc_p (T_{1A} - T_2)$$

$$Q_{\text{source,out}} = mc_p (T_{1A} - T_2) = (30 \text{ kg})(1.005 \text{ kJ/kg}\cdot\text{K})(900 - 519.6)\text{K} = 11,469 \text{ kJ}$$

Sink:

$$Q_{\text{sink,in}} - W_{b,\text{out}} = \Delta U \rightarrow Q_{\text{sink,in}} = \Delta H = mc_p (T_2 - T_{1A})$$

$$Q_{\text{sink,in}} = mc_p (T_2 - T_{1B}) = (30 \text{ kg})(1.005 \text{ kJ/kg}\cdot\text{K})(519.6 - 300)\text{K} = 6621 \text{ kJ}$$

Then the work produced becomes

$$W_{\text{max,out}} = Q_H - Q_L = Q_{\text{source,out}} - Q_{\text{sink,in}} = 11,469 - 6621 = \mathbf{4847 \text{ kJ}}$$

Therefore, a maximum of 4847 kJ of work can be produced during this process

8-117 A heat engine operates between a nitrogen tank and an argon cylinder at different temperatures. The maximum work that can be produced and the final temperatures are to be determined.

Assumptions Nitrogen and argon are ideal gases with constant specific heats at room temperature.

Properties The constant volume specific heat of nitrogen at room temperature is $c_v = 0.743 \text{ kJ/kg}\cdot\text{K}$. The constant pressure specific heat of argon at room temperature is $c_p = 0.5203 \text{ kJ/kg}\cdot\text{K}$ (Table A-2).

Analysis For maximum power production, the entropy generation must be zero. We take the tank, the cylinder (the heat source and the heat sink) and the heat engine as the system. Noting that the system involves no heat and mass transfer and that the entropy change for cyclic devices is zero, the entropy balance can be expressed as

$$\underbrace{S_{\text{in}} - S_{\text{out}}}_{\substack{\text{Net entropy transfer} \\ \text{by heat and mass}}} + \underbrace{S_{\text{gen}}^{\nearrow 0}}_{\substack{\text{Entropy} \\ \text{generation}}} = \underbrace{\Delta S_{\text{system}}}_{\substack{\text{Change} \\ \text{in entropy}}}$$

$$0 + S_{\text{gen}}^{\nearrow 0} = \Delta S_{\text{tank,source}} + \Delta S_{\text{cylinder,sink}} + \Delta S_{\text{heat engine}}^{\nearrow 0}$$

$$(\Delta S)_{\text{source}} + (\Delta S)_{\text{sink}} = 0$$

$$\left(mc_v \ln \frac{T_2}{T_1} - mR \ln \frac{V_2}{V_1} \right)_{\text{source}} + 0 + \left(mc_p \ln \frac{T_2}{T_1} - mR \ln \frac{P_2}{P_1} \right)_{\text{sink}} = 0$$

Substituting,

$$(30 \text{ kg})(0.743 \text{ kJ/kg}\cdot\text{K}) \ln \frac{T_2}{900 \text{ K}} + (15 \text{ kg})(0.5203 \text{ kJ/kg}\cdot\text{K}) \ln \frac{T_2}{300 \text{ K}} = 0$$

Solving for T_2 yields

$$T_2 = \mathbf{676.9 \text{ K}}$$

where T_2 is the common final temperature of the tanks for maximum power production.

The energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ for the source and sink can be expressed as follows:

Source:

$$-Q_{\text{source,out}} = \Delta U = mc_v(T_2 - T_{1A}) \rightarrow Q_{\text{source,out}} = mc_v(T_{1A} - T_2)$$

$$Q_{\text{source,out}} = mc_v(T_{1A} - T_2) = (30 \text{ kg})(0.743 \text{ kJ/kg}\cdot\text{K})(900 - 676.9)\text{K} = 4973 \text{ kJ}$$

Sink:

$$Q_{\text{sink,in}} - W_{\text{b,out}} = \Delta U \rightarrow Q_{\text{sink,in}} = \Delta H = mc_p(T_2 - T_{1A})$$

$$Q_{\text{sink,in}} = mc_p(T_2 - T_{1A}) = (15 \text{ kg})(0.5203 \text{ kJ/kg}\cdot\text{K})(676.9 - 300)\text{K} = 2941 \text{ kJ}$$

Then the work produced becomes

$$W_{\text{max,out}} = Q_H - Q_L = Q_{\text{source,out}} - Q_{\text{sink,in}} = 4973 - 2941 = \mathbf{2032 \text{ kJ}}$$

Therefore, a maximum of 2032 kJ of work can be produced during this process.

8-118 A rigid tank containing nitrogen is considered. Nitrogen is allowed to escape until the mass of nitrogen becomes one-half of its initial mass. The change in the nitrogen's work potential is to be determined.

Assumptions 1 This is an unsteady process since the conditions within the device are changing during the process. **2** Kinetic and potential energies are negligible. **3** There are no work interactions involved. **4** Nitrogen is an ideal gas with constant specific heats.

Properties The properties of nitrogen at room temperature are $c_p = 1.039$ kJ/kg·K, $c_v = 0.743$ kJ/kg·K, $k = 1.4$, and $R = 0.2968$ kJ/kg·K (Table A-2a).

Analysis The initial and final masses in the tank are

$$m_1 = \frac{P_1 V}{RT_1} = \frac{(1000 \text{ kPa})(0.100 \text{ m}^3)}{(0.2968 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(293 \text{ K})} = 1.150 \text{ kg}$$

$$m_2 = m_e = \frac{m_1}{2} = \frac{1.150 \text{ kg}}{2} = 0.575 \text{ kg}$$

We take the tank as the system, which is a control volume since mass crosses the boundary. Noting that the microscopic energies of flowing and nonflowing fluids are represented by enthalpy h and internal energy u , respectively, the mass and energy balances for this uniform-flow system can be expressed as

Mass balance:

$$m_{\text{in}} - m_{\text{out}} = \Delta m_{\text{system}} \rightarrow m_e = m_2$$

Energy balance:

$$\underbrace{E_{\text{in}} - E_{\text{out}}}_{\substack{\text{Net energy transfer} \\ \text{by heat, work, and mass}}} = \underbrace{\Delta E_{\text{system}}}_{\substack{\text{Change in internal, kinetic,} \\ \text{potential, etc. energies}}}$$

$$-m_e h_e = m_2 u_2 - m_1 u_1$$

Using the average of the initial and final temperatures for the exiting nitrogen, this energy balance equation becomes

$$\begin{aligned} -m_e h_e &= m_2 u_2 - m_1 u_1 \\ -m_e c_p T_e &= m_2 c_v T_2 - m_1 c_v T_1 \\ -(0.575)(1.039)(0.5)(293 + T_2) &= (0.575)(0.743)T_2 - (1.150)(0.743)(293) \end{aligned}$$

Solving for the final temperature, we get

$$T_2 = 224.3 \text{ K}$$

The final pressure in the tank is

$$P_2 = \frac{m_2 R T_2}{V} = \frac{(0.575 \text{ kg})(0.2968 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(224.3 \text{ K})}{0.100 \text{ m}^3} = 382.8 \text{ kPa}$$

The average temperature and pressure for the exiting nitrogen is

$$T_e = 0.5(T_1 + T_2) = 0.5(293 + 224.3) = 258.7 \text{ K}$$

$$P_e = 0.5(P_1 + P_2) = 0.5(1000 + 382.8) = 691.4 \text{ kPa}$$

The work potential associated with this process is equal to the exergy destroyed during the process. The exergy destruction during a process can be determined from an exergy balance or directly from its definition $X_{\text{destroyed}} = T_0 S_{\text{gen}}$. The entropy generation S_{gen} in this case is determined from an entropy balance on the system:

$$\underbrace{S_{\text{in}} - S_{\text{out}}}_{\substack{\text{Net entropy transfer} \\ \text{by heat and mass}}} + \underbrace{S_{\text{gen}}}_{\substack{\text{Entropy} \\ \text{generation}}} = \underbrace{\Delta S_{\text{system}}}_{\substack{\text{Change} \\ \text{in entropy}}}$$

$$\begin{aligned} -m_e s_e + S_{\text{gen}} &= \Delta S_{\text{tank}} = m_2 s_2 - m_1 s_1 \\ S_{\text{gen}} &= m_2 s_2 - m_1 s_1 + m_e s_e \end{aligned}$$

Rearranging and substituting gives

$$\begin{aligned}
 S_{\text{gen}} &= m_2 s_2 - m_1 s_1 + m_e s_e \\
 &= m_2 (c_p \ln T_2 - R \ln P_2) - m_1 (c_p \ln T_1 - R \ln P_1) + m_e (c_p \ln T_e - R \ln P_e) \\
 &= (0.575) [1.039 \ln(224.3) - (0.2968) \ln(382.8)] - (1.15) [1.039 \ln(293) - (0.2968) \ln(1000)] \\
 &\quad + (0.575) [1.039 \ln(258.7) - (0.2968) \ln(691.4)] \\
 &= 2.2188 - 4.4292 + 2.2032 = -0.007152 \text{ kJ/K}
 \end{aligned}$$

Then,

$$W_{\text{rev}} = X_{\text{destroyed}} = T_0 S_{\text{gen}} = (293 \text{ K})(-0.007152 \text{ kJ/K}) = \mathbf{-2.10 \text{ kJ}}$$

The entropy generation cannot be negative for a thermodynamically possible process. This result is probably due to using average temperature and pressure values for the exiting gas and using constant specific heats for nitrogen. This sensitivity occurs because the entropy generation is very small in this process.

Alternative More Accurate Solution

This problem may also be solved by considering the variation of gas temperature and pressure at the outlet of the tank. The mass balance in this case is

$$\dot{m}_e = -\frac{dm}{dt}$$

which when combined with the reduced first law gives

$$\frac{d(mu)}{dt} = h \frac{dm}{dt}$$

Using the specific heats and the ideal gas equation of state reduces this to

$$c_v \frac{V dP}{R dt} = c_p T \frac{dm}{dt}$$

which upon rearrangement and an additional use of ideal gas equation of state becomes

$$\frac{1}{P} \frac{dP}{dt} = \frac{c_p}{c_v} \frac{1}{m} \frac{dm}{dt}$$

When this is integrated, the result is

$$P_2 = P_1 \left(\frac{m_2}{m_1} \right)^k = 1000 \left(\frac{1}{2} \right)^{1.4} = 378.9 \text{ kPa}$$

The final temperature is then

$$T_2 = \frac{P_2 V}{m_2 R} = \frac{(378.9 \text{ kPa})(0.100 \text{ m}^3)}{(0.575 \text{ kg})(0.2968 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})} = 222.0 \text{ K}$$

The process is then one of

$$\frac{m^k}{P} = \text{const} \quad \text{or} \quad \frac{m^{k-1}}{T} = \text{const}$$

The reduced combined first and second law becomes

$$\dot{W}_{\text{rev}} = -\frac{d(U - T_0 S)}{dt} + (h - T_0 s) \frac{dm}{dt}$$

when the mass balance is substituted and the entropy generation is set to zero (for maximum work production). Replacing the enthalpy term with the first law result and canceling the common dU/dt term reduces this to

$$\dot{W}_{\text{rev}} = T_0 \frac{d(ms)}{dt} - T_0 s \frac{dm}{dt}$$

Expanding the first derivative and canceling the common terms further reduces this to

$$\dot{W}_{\text{rev}} = T_0 m \frac{ds}{dt}$$

Letting $a = P_1 / m_1^k$ and $b = T_1 / m_1^{k-1}$, the pressure and temperature of the nitrogen in the system are related to the mass by

$$P = am^k \quad \text{and} \quad T = bm^{k-1}$$

according to the first law. Then,

$$dP = akm^{k-1} dm \quad \text{and} \quad dT = b(k-1)m^{k-2} dm$$

The entropy change relation then becomes

$$ds = c_p \frac{dT}{T} - R \frac{dP}{P} = [(k-1)c_p - Rk] \frac{dm}{m}$$

Now, multiplying the combined first and second laws by dt and integrating the result gives

$$\begin{aligned} W_{\text{rev}} &= T_0 \int_1^2 m ds = T_0 \int_1^2 m ds [(k-1)c_p - Rk] dm \\ &= T_0 [(k-1)c_p - Rk] (m_2 - m_1) \\ &= (293)[(1.4-1)(1.039) - (0.2968)(1.4)](0.575 - 1.15) \\ &= \mathbf{-0.0135kJ} \end{aligned}$$

Once again the entropy generation is negative, which cannot be the case for a thermodynamically possible process. This is probably due to using constant specific heats for nitrogen. This sensitivity occurs because the entropy generation is very small in this process.

8-119 A pressure cooker is initially half-filled with liquid water. It is kept on the heater for 30 min. The amount water that remained in the cooker and the exergy destroyed are to be determined.

Assumptions 1 This is an unsteady process since the conditions within the device are changing during the process, but it can be analyzed as a uniform-flow process since the state of water vapor leaving the cooker remains constant. **2** Kinetic and potential energies are negligible. **3** Heat loss from the cooker is negligible.

Properties The properties of water are (Tables A-4 through A-6)

$$P_1 = 175 \text{ kPa} \rightarrow \nu_f = 0.001057 \text{ m}^3/\text{kg}, \nu_g = 1.0037 \text{ m}^3/\text{kg}$$

$$u_f = 486.82 \text{ kJ/kg}, u_g = 2524.5 \text{ kJ/kg}$$

$$s_f = 1.4850 \text{ kJ/kg}\cdot\text{K}, s_g = 7.1716 \text{ kJ/kg}\cdot\text{K}$$

$$P_e = 175 \text{ kPa} \left\{ \begin{array}{l} h_e = h_g @ 175 \text{ kPa} = 2700.2 \text{ kJ/kg} \\ \text{sat. vapor} \quad \left\{ \begin{array}{l} s_e = s_g @ 175 \text{ kPa} = 7.1716 \text{ kJ/kg}\cdot\text{K} \end{array} \right. \end{array} \right.$$

Analysis (a) We take the cooker as the system, which is a control volume since mass crosses the boundary. Noting that the microscopic energies of flowing and nonflowing fluids are represented by enthalpy h and internal energy u , respectively, the mass and energy balances for this uniform-flow system can be expressed as

$$\text{Mass balance:} \quad m_{\text{in}} - m_{\text{out}} = \Delta m_{\text{system}} \rightarrow m_e = m_1 - m_2$$

$$\text{Energy balance:} \quad \underbrace{E_{\text{in}} - E_{\text{out}}}_{\substack{\text{Net energy transfer} \\ \text{by heat, work, and mass}}} = \underbrace{\Delta E_{\text{system}}}_{\substack{\text{Change in internal, kinetic,} \\ \text{potential, etc. energies}}}$$

$$W_{e,\text{in}} - m_e h_e = m_2 u_2 - m_1 u_1 \quad (\text{since } Q \cong \text{ke} \cong \text{pe} \cong 0)$$

The initial mass, initial internal energy, initial entropy, and final mass in the tank are

$$\nu_f = \nu_g = 2 \text{ L} = 0.002 \text{ m}^3$$

$$m_1 = m_f + m_g = \frac{\nu_f}{\nu_f} + \frac{\nu_g}{\nu_g} = \frac{0.002 \text{ m}^3}{0.001057 \text{ m}^3/\text{kg}} + \frac{0.002 \text{ m}^3}{1.0037 \text{ m}^3/\text{kg}} = 1.893 + 0.002 = 1.8945 \text{ kg}$$

$$U_1 = m_1 u_1 = m_f u_f + m_g u_g = 1.893 \times 486.82 + 0.002 \times 2524.5 = 926.6 \text{ kJ}$$

$$S_1 = m_1 s_1 = m_f s_f + m_g s_g = 1.892 \times 1.4850 + 0.002 \times 7.1716 = 2.8239 \text{ kJ/K}$$

$$m_2 = \frac{\nu}{\nu_2} = \frac{0.004 \text{ m}^3}{\nu_2}$$

The amount of electrical energy supplied during this process is

$$W_{e,\text{in}} = \dot{W}_{e,\text{in}} \Delta t = (0.750 \text{ kJ/s})(20 \times 60 \text{ s}) = 900 \text{ kJ}$$

Then from the mass and energy balances,

$$m_e = m_1 - m_2 = 1.894 - \frac{0.004}{\nu_2}$$

$$900 \text{ kJ} = \left(1.894 - \frac{0.004}{\nu_2}\right)(2700.2 \text{ kJ/kg}) + \left(\frac{0.004}{\nu_2}\right)(u_2) - 926.6 \text{ kJ}$$

Substituting $u_2 = u_f + x_2 u_{fg}$ and $\nu_2 = \nu_f + x_2 \nu_{fg}$, and solving for x_2 yields

$$x_2 = 0.001918$$

Thus,

$$\nu_2 = \nu_f + x_2 \nu_{fg} = 0.001057 + 0.001918 \times (1.0037 - 0.001057) = 0.002654 \text{ m}^3 / \text{kg}$$

$$s_2 = s_f + x_2 s_{fg} = 1.4850 + 0.001918 \times 5.6865 = 1.5642 \text{ kJ} / \text{kg} \cdot \text{K}$$

and

$$m_2 = \frac{\mathcal{V}}{\nu_2} = \frac{0.004 \text{ m}^3}{0.002654 \text{ m}^3 / \text{kg}} = \mathbf{1.507 \text{ kg}}$$

(b) The entropy generated during this process is determined by applying the entropy balance on the cooker. Noting that there is no heat transfer and some mass leaves, the entropy balance can be expressed as

$$\underbrace{S_{\text{in}} - S_{\text{out}}}_{\substack{\text{Net entropy transfer} \\ \text{by heat and mass}}} + \underbrace{S_{\text{gen}}}_{\substack{\text{Entropy} \\ \text{generation}}} = \underbrace{\Delta S_{\text{system}}}_{\substack{\text{Change} \\ \text{in entropy}}}$$

$$-m_e s_e + S_{\text{gen}} = \Delta S_{\text{sys}} = m_2 s_2 - m_1 s_1$$

$$S_{\text{gen}} = m_e s_e + m_2 s_2 - m_1 s_1$$

The exergy destroyed during a process can be determined from an exergy balance or directly from its definition $X_{\text{destroyed}} = T_0 S_{\text{gen}}$. Using the S_{gen} relation obtained above and substituting,

$$X_{\text{destroyed}} = T_0 S_{\text{gen}} = T_0 (m_e s_e + m_2 s_2 - m_1 s_1)$$

$$= (298 \text{ K})[(1.894 - 1.507) \times 7.1716 + 1.507 \times 1.5642 - 2.8239]$$

$$= \mathbf{689 \text{ kJ}}$$

8-120 A pressure cooker is initially half-filled with liquid water. Heat is transferred to the cooker for 30 min. The amount of water that remained in the cooker and the exergy destroyed are to be determined.

Assumptions 1 This is an unsteady process since the conditions within the device are changing during the process, but it can be analyzed as a uniform-flow process since the state of water vapor leaving the cooker remains constant. **2** Kinetic and potential energies are negligible. **3** Heat loss from the cooker is negligible.

Properties The properties of water are (Tables A-4 through A-6)

$$P_1 = 175 \text{ kPa} \rightarrow \nu_f = 0.001057 \text{ m}^3/\text{kg}, \nu_g = 1.0037 \text{ m}^3/\text{kg}$$

$$u_f = 486.82 \text{ kJ/kg}, u_g = 2524.5 \text{ kJ/kg}$$

$$s_f = 1.4850 \text{ kJ/kg}\cdot\text{K}, s_g = 7.1716 \text{ kJ/kg}\cdot\text{K}$$

$$P_e = 175 \text{ kPa} \left\{ \begin{array}{l} h_e = h_g @ 175 \text{ kPa} = 2700.2 \text{ kJ/kg} \\ \text{sat. vapor} \quad \left\{ \begin{array}{l} s_e = s_g @ 175 \text{ kPa} = 7.1716 \text{ kJ/kg}\cdot\text{K} \end{array} \right. \end{array} \right.$$

Analysis (a) We take the cooker as the system, which is a control volume since mass crosses the boundary. Noting that the microscopic energies of flowing and nonflowing fluids are represented by enthalpy h and internal energy u , respectively, the mass and energy balances for this uniform-flow system can be expressed as

$$\text{Mass balance:} \quad m_{\text{in}} - m_{\text{out}} = \Delta m_{\text{system}} \rightarrow m_e = m_1 - m_2$$

$$\text{Energy balance:} \quad \underbrace{E_{\text{in}} - E_{\text{out}}}_{\text{Net energy transfer by heat, work, and mass}} = \underbrace{\Delta E_{\text{system}}}_{\text{Change in internal, kinetic, potential, etc. energies}}$$

$$Q_{\text{in}} - m_e h_e = m_2 u_2 - m_1 u_1 \quad (\text{since } W \cong \text{ke} \cong \text{pe} \cong 0)$$

The initial mass, initial internal energy, initial entropy, and final mass in the tank are

$$\nu_f = \nu_g = 2 \text{ L} = 0.002 \text{ m}^3$$

$$m_1 = m_f + m_g = \frac{\nu_f}{\nu_f} + \frac{\nu_g}{\nu_g} = \frac{0.002 \text{ m}^3}{0.001057 \text{ m}^3/\text{kg}} + \frac{0.002 \text{ m}^3}{1.0037 \text{ m}^3/\text{kg}} = 1.893 + 0.002 = 1.8945 \text{ kg}$$

$$U_1 = m_1 u_1 = m_f u_f + m_g u_g = 1.893 \times 486.82 + 0.002 \times 2524.5 = 926.6 \text{ kJ}$$

$$S_1 = m_1 s_1 = m_f s_f + m_g s_g = 1.892 \times 1.4850 + 0.002 \times 7.1716 = 2.8239 \text{ kJ/K}$$

$$m_2 = \frac{\nu}{\nu_2} = \frac{0.004 \text{ m}^3}{\nu_2}$$

The amount of heat transfer during this process is

$$Q = \dot{Q} \Delta t = (0.750 \text{ kJ/s})(20 \times 60 \text{ s}) = 900 \text{ kJ}$$

Then from the mass and energy balances,

$$m_e = m_1 - m_2 = 1.894 - \frac{0.004}{\nu_2}$$

$$900 \text{ kJ} = \left(1.894 - \frac{0.004}{\nu_2}\right)(2700.2 \text{ kJ/kg}) + \left(\frac{0.004}{\nu_2}\right)(u_2) - 926.6 \text{ kJ}$$

Substituting $u_2 = u_f + x_2 u_{fg}$ and $\nu_2 = \nu_f + x_2 \nu_{fg}$, and solving for x_2 yields

$$x_2 = 0.001918$$

Thus,

$$v_2 = v_f + x_2 v_{fg} = 0.001057 + 0.001918 \times (1.0037 - 0.001057) = 0.002654 \text{ m}^3 / \text{kg}$$

$$s_2 = s_f + x_2 s_{fg} = 1.4850 + 0.001918 \times 5.6865 = 1.5642 \text{ kJ} / \text{kg} \cdot \text{K}$$

and

$$m_2 = \frac{V}{v_2} = \frac{0.004 \text{ m}^3}{0.002654 \text{ m}^3 / \text{kg}} = \mathbf{1.507 \text{ kg}}$$

(b) The entropy generated during this process is determined by applying the entropy balance on an *extended system* that includes the cooker and its immediate surroundings so that the boundary temperature of the extended system at the location of heat transfer is the heat source temperature, $T_{\text{source}} = 180^\circ\text{C}$ at all times. The entropy balance for it can be expressed as

$$\underbrace{S_{\text{in}} - S_{\text{out}}}_{\substack{\text{Net entropy transfer} \\ \text{by heat and mass}}} + \underbrace{S_{\text{gen}}}_{\substack{\text{Entropy} \\ \text{generation}}} = \underbrace{\Delta S_{\text{system}}}_{\substack{\text{Change} \\ \text{in entropy}}}$$

$$\frac{Q_{\text{in}}}{T_{\text{b,in}}} - m_e s_e + S_{\text{gen}} = \Delta S_{\text{sys}} = m_2 s_2 - m_1 s_1$$

$$S_{\text{gen}} = m_e s_e + m_2 s_2 - m_1 s_1 - \frac{Q_{\text{in}}}{T_{\text{source}}}$$

The exergy destroyed during a process can be determined from an exergy balance or directly from its definition $X_{\text{destroyed}} = T_0 S_{\text{gen}}$. Using the S_{gen} relation obtained above and substituting,

$$X_{\text{destroyed}} = T_0 S_{\text{gen}} = T_0 \left(m_e s_e + m_2 s_2 - m_1 s_1 - \frac{Q_{\text{in}}}{T_{\text{source}}} \right)$$

$$= (298 \text{ K})[(1.894 - 1.507) \times 7.1716 + 1.507 \times 1.5642 - 2.8239 - 900 / 453]$$

$$= \mathbf{96.8 \text{ kJ}}$$

Note that the exergy destroyed is much less when heat is supplied from a heat source rather than an electric resistance heater.

8-121 Steam is condensed by cooling water in the condenser of a power plant. The rate of condensation of steam and the rate of exergy destruction are to be determined.

Assumptions 1 Steady operating conditions exist. 2 The heat exchanger is well-insulated so that heat loss to the surroundings is negligible and thus heat transfer from the hot fluid is equal to the heat transfer to the cold fluid. 3 Changes in the kinetic and potential energies of fluid streams are negligible. 4 Fluid properties are constant.

Properties The enthalpy and entropy of vaporization of water at 50°C are $h_{fg} = 2382.0$ kJ/kg and $s_{fg} = 7.3710$ kJ/kg.K (Table A-4). The specific heat of water at room temperature is $c_p = 4.18$ kJ/kg.°C (Table A-3).

Analysis (a) We take the cold water tubes as the system, which is a control volume. The energy balance for this steady-flow system can be expressed in the rate form as

$$\underbrace{\dot{E}_{in} - \dot{E}_{out}}_{\text{Rate of net energy transfer by heat, work, and mass}} = \underbrace{\Delta \dot{E}_{system}}_{\substack{\text{Rate of change in internal, kinetic,} \\ \text{potential, etc. energies}}} \stackrel{\neq 0 \text{ (steady)}}{=} 0$$

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{Q}_{in} + \dot{m}h_1 = \dot{m}h_2 \quad (\text{since } \Delta ke \cong \Delta pe \cong 0)$$

$$\dot{Q}_{in} = \dot{m}c_p(T_2 - T_1)$$

Then the heat transfer rate to the cooling water in the condenser becomes

$$\begin{aligned} \dot{Q} &= [\dot{m}c_p(T_{out} - T_{in})]_{\text{cooling water}} \\ &= (240 \text{ kg/s})(4.18 \text{ kJ/kg}\cdot\text{°C})(20\text{°C} - 12\text{°C}) \\ &= 8026 \text{ kJ/s} \end{aligned}$$

The rate of condensation of steam is determined to be

$$\dot{Q} = (\dot{m}h_{fg})_{\text{steam}} \longrightarrow \dot{m}_{\text{steam}} = \frac{\dot{Q}}{h_{fg}} = \frac{8026 \text{ kJ/s}}{2382.0 \text{ kJ/kg}} = \mathbf{3.369 \text{ kg/s}}$$

(b) The rate of entropy generation within the condenser during this process can be determined by applying the rate form of the entropy balance on the entire condenser. Noting that the condenser is well-insulated and thus heat transfer is negligible, the entropy balance for this steady-flow system can be expressed as

$$\underbrace{\dot{S}_{in} - \dot{S}_{out}}_{\text{Rate of net entropy transfer by heat and mass}} + \underbrace{\dot{S}_{gen}}_{\text{Rate of entropy generation}} = \underbrace{\Delta \dot{S}_{system}}_{\substack{\neq 0 \text{ (steady)}}} \stackrel{\neq 0 \text{ (steady)}}{=} 0$$

$$\dot{m}_1 s_1 + \dot{m}_3 s_3 - \dot{m}_2 s_2 - \dot{m}_4 s_4 + \dot{S}_{gen} = 0 \quad (\text{since } \dot{Q} = 0)$$

$$\dot{m}_{\text{water}} s_1 + \dot{m}_{\text{steam}} s_3 - \dot{m}_{\text{water}} s_2 - \dot{m}_{\text{steam}} s_4 + \dot{S}_{gen} = 0$$

$$\dot{S}_{gen} = \dot{m}_{\text{water}}(s_2 - s_1) + \dot{m}_{\text{steam}}(s_4 - s_3)$$

Noting that water is an incompressible substance and steam changes from saturated vapor to saturated liquid, the rate of entropy generation is determined to be

$$\begin{aligned} \dot{S}_{gen} &= \dot{m}_{\text{water}} c_p \ln \frac{T_2}{T_1} + \dot{m}_{\text{steam}}(s_f - s_g) = \dot{m}_{\text{water}} c_p \ln \frac{T_2}{T_1} - \dot{m}_{\text{steam}} s_{fg} \\ &= (240 \text{ kg/s})(4.18 \text{ kJ/kg}\cdot\text{K}) \ln \frac{20 + 273}{12 + 273} - (3.369 \text{ kg/s})(7.3710 \text{ kJ/kg}\cdot\text{K}) \\ &= 2.937 \text{ kW/K} \end{aligned}$$

Then the exergy destroyed can be determined directly from its definition $X_{\text{destroyed}} = T_0 \dot{S}_{gen}$ to be

$$\dot{X}_{\text{destroyed}} = T_0 \dot{S}_{gen} = (285 \text{ K})(2.937 \text{ kW/K}) = \mathbf{837 \text{ kW}}$$

8-122 A system consisting of a compressor, a storage tank, and a turbine as shown in the figure is considered. The change in the exergy of the air in the tank and the work required to compress the air as the tank was being filled are to be determined.

Assumptions 1 Changes in the kinetic and potential energies are negligible. **4** Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $R = 0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$, $c_p = 1.005 \text{ kJ}/\text{kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ}/\text{kg}\cdot\text{K}$, $k = 1.4$ (Table A-2a).

Analysis The initial mass of air in the tank is

$$m_{\text{initial}} = \frac{P_{\text{initial}}\mathcal{V}}{RT_{\text{initial}}} = \frac{(100 \text{ kPa})(5 \times 10^5 \text{ m}^3)}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(293 \text{ K})} = 0.5946 \times 10^6 \text{ kg}$$

and the final mass in the tank is

$$m_{\text{final}} = \frac{P_{\text{final}}\mathcal{V}}{RT_{\text{final}}} = \frac{(600 \text{ kPa})(5 \times 10^5 \text{ m}^3)}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(293 \text{ K})} = 3.568 \times 10^6 \text{ kg}$$

Since the compressor operates as an isentropic device,

$$T_2 = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k}$$

The conservation of mass applied to the tank gives

$$\frac{dm}{dt} = \dot{m}_{\text{in}}$$

while the first law gives

$$\dot{Q} = \frac{d(mu)}{dt} - h \frac{dm}{dt}$$

Employing the ideal gas equation of state and using constant specific heats, expands this result to

$$\dot{Q} = \frac{\mathcal{V}c_v}{R} \frac{dP}{dt} - c_p T_2 \frac{\mathcal{V}}{RT} \frac{dP}{dt}$$

Using the temperature relation across the compressor and multiplying by dt puts this result in the form

$$\dot{Q}dt = \frac{\mathcal{V}c_v}{R} dP - c_p T_1 \left(\frac{P}{P_1} \right)^{(k-1)/k} \frac{\mathcal{V}}{RT} dP$$

When this integrated, it yields (i and f stand for initial and final states)

$$\begin{aligned} Q &= \frac{\mathcal{V}c_v}{R} (P_f - P_i) - \frac{k}{2k-1} \frac{c_p \mathcal{V}}{R} \left[P_f \left(\frac{P_f}{P_i} \right)^{(k-1)/k} - P_i \right] \\ &= \frac{(5 \times 10^5)(0.718)}{0.287} (600 - 100) - \frac{1.4}{2(1.4) - 1} \frac{(1.005)(5 \times 10^5)}{0.287} \left[600 \left(\frac{600}{100} \right)^{0.4/1.4} - 100 \right] \\ &= -6.017 \times 10^8 \text{ kJ} \end{aligned}$$

The negative result show that heat is transferred from the tank. Applying the first law to the tank and compressor gives

$$(\dot{Q} - \dot{W}_{\text{out}})dt = d(mu) - h_1 dm$$

which integrates to

$$Q - W_{\text{out}} = (m_f u_f - m_i u_i) - h_1 (m_f - m_i)$$

Upon rearrangement,

$$\begin{aligned} W_{\text{out}} &= Q + (c_p - c_v)T(m_f - m_i) \\ &= -6.017 \times 10^8 + (1.005 - 0.718)(293)[(3.568 - 0.5946) \times 10^6] \\ &= \mathbf{-3.516 \times 10^8 \text{ kJ}} \end{aligned}$$

The negative sign shows that work is done on the compressor. When the combined first and second laws is reduced to fit the compressor and tank system and the mass balance incorporated, the result is

$$\dot{W}_{\text{rev}} = \dot{Q} \left(1 - \frac{T_0}{T_R} \right) - \frac{d(U - T_0 S)}{dt} + (h - T_0 s) \frac{dm}{dt}$$

which when integrated over the process becomes

$$\begin{aligned} W_{\text{rev}} &= Q \left(1 - \frac{T_0}{T_R} \right) + m_i [(u_i - h_1) - T_0 (s_i - s_1)] - m_f [(u_f - h_1) - T_0 (s_f - s_1)] \\ &= Q \left(1 - \frac{T_0}{T_R} \right) + m_i [T_i (c_v - c_p)] - m_f \left[T_f (c_v - c_p) - T_0 R \ln \left(\frac{P_f}{P_i} \right) \right] \\ &= -6.017 \times 10^8 \left(1 - \frac{293}{293} \right) + 0.5946 \times 10^6 [(0.718 - 1.005)293] \\ &\quad - 3.568 \times 10^6 \left[(0.718 - 1.005)293 + 293(0.287) \ln \frac{600}{100} \right] \\ &= \mathbf{7.875 \times 10^8 \text{ kJ}} \end{aligned}$$

This is the exergy change of the air stored in the tank.

8-123 The air stored in the tank of the system shown in the figure is released through the isentropic turbine. The work produced and the change in the exergy of the air in the tank are to be determined.

Assumptions 1 Changes in the kinetic and potential energies are negligible. **4** Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $R = 0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$, $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, $k = 1.4$ (Table A-2a).

Analysis The initial mass of air in the tank is

$$m_{\text{initial}} = \frac{P_{\text{initial}}\mathcal{V}}{RT_{\text{initial}}} = \frac{(600 \text{ kPa})(5 \times 10^5 \text{ m}^3)}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(293 \text{ K})} = 3.568 \times 10^6 \text{ kg}$$

and the final mass in the tank is

$$m_{\text{final}} = \frac{P_{\text{final}}\mathcal{V}}{RT_{\text{final}}} = \frac{(100 \text{ kPa})(5 \times 10^5 \text{ m}^3)}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(293 \text{ K})} = 0.5946 \times 10^6 \text{ kg}$$

The conservation of mass is

$$\frac{dm}{dt} = \dot{m}_{\text{in}}$$

while the first law gives

$$\dot{Q} = \frac{d(mu)}{dt} - h \frac{dm}{dt}$$

Employing the ideal gas equation of state and using constant specific heats, expands this result to

$$\begin{aligned} \dot{Q} &= \frac{\mathcal{V}c_v}{R} \frac{dP}{dt} - c_p T \frac{\mathcal{V}}{RT} \frac{dP}{dt} \\ &= \frac{c_v - c_p}{R} \mathcal{V} \frac{dP}{dt} \\ &= -\mathcal{V} \frac{dP}{dt} \end{aligned}$$

When this is integrated over the process, the result is (i and f stand for initial and final states)

$$Q = -\mathcal{V}(P_f - P_i) = -5 \times 10^5 (100 - 600) = 2.5 \times 10^8 \text{ kJ}$$

Applying the first law to the tank and compressor gives

$$(\dot{Q} - \dot{W}_{\text{out}})dt = d(mu) - hdm$$

which integrates to

$$\begin{aligned} Q - W_{\text{out}} &= (m_f u_f - m_i u_i) + h(m_i - m_f) \\ -W_{\text{out}} &= -Q + m_f u_f - m_i u_i + h(m_i - m_f) \\ W_{\text{out}} &= Q - m_f u_f + m_i u_i - h(m_i - m_f) \\ &= Q - m_f c_v T + m_i c_p T - c_p T(m_i - m_f) \\ &= 2.5 \times 10^8 - (0.5946 \times 10^6)(0.718)(293) + (3.568 \times 10^6)(1.005)(293) \\ &\quad - (1.005)(293)(3.568 \times 10^6 - 0.5946 \times 10^6) \\ &= \mathbf{3.00 \times 10^8 \text{ kJ}} \end{aligned}$$

This is the work output from the turbine. When the combined first and second laws is reduced to fit the turbine and tank system and the mass balance incorporated, the result is

$$\begin{aligned}
\dot{W}_{\text{rev}} &= \dot{Q} \left(1 - \frac{T_0}{T_R} \right) - \frac{d(U - T_0 S)}{dt} + (h - T_0 s) \frac{dm}{dt} \\
&= \dot{Q} \left(1 - \frac{T_0}{T_R} \right) - (u - T_0 s) \frac{dm}{dt} - m \frac{d(u - T_0 s)}{dt} + (h - T_0 s) \frac{dm}{dt} \\
&= \dot{Q} \left(1 - \frac{T_0}{T_R} \right) + (c_p - c_v) T \frac{dm}{dt} + m T_0 \frac{ds}{dt} \\
&= \dot{Q} \left(1 - \frac{T_0}{T_R} \right) + (c_p - c_v) T \frac{dm}{dt} + \nu \frac{T_0}{T} (P_f - P_i)
\end{aligned}$$

where the last step uses entropy change equation. When this is integrated over the process it becomes

$$\begin{aligned}
W_{\text{rev}} &= Q \left(1 - \frac{T_0}{T_R} \right) + (c_p - c_v) T (m_f - m_i) + \nu \frac{T_0}{T} (P_f - P_i) \\
&= 3.00 \times 10^8 \left(1 - \frac{293}{293} \right) + (1.005 - 0.718)(293)(0.5946 - 3.568) \times 10^6 + 5 \times 10^5 \frac{293}{293} (100 - 600) \\
&= 0 - 2.500 \times 10^8 - 2.5 \times 10^8 \\
&= \mathbf{-5.00 \times 10^8 \text{ kJ}}
\end{aligned}$$

This is the exergy change of the air in the storage tank.

8-124 A heat engine operates between a tank and a cylinder filled with air at different temperatures. The maximum work that can be produced and the final temperatures are to be determined.

Assumptions Air is an ideal gas with constant specific heats at room temperature.

Properties The specific heats of air are $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$ and $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ (Table A-2).

Analysis For maximum power production, the entropy generation must be zero. We take the tank, the cylinder (the heat source and the heat sink) and the heat engine as the system. Noting that the system involves no heat and mass transfer and that the entropy change for cyclic devices is zero, the entropy balance can be expressed as

$$\underbrace{S_{\text{in}} - S_{\text{out}}}_{\text{Net entropy transfer by heat and mass}} + \underbrace{S_{\text{gen}}}_{\text{Entropy generation}} \stackrel{\approx 0}{=} \underbrace{\Delta S_{\text{system}}}_{\text{Change in entropy}}$$

$$0 + S_{\text{gen}} \stackrel{\approx 0}{=} \Delta S_{\text{tank,source}} + \Delta S_{\text{cylinder,sink}} + \Delta S_{\text{heat engine}} \stackrel{\approx 0}{=}$$

$$(\Delta S)_{\text{source}} + (\Delta S)_{\text{sink}} = 0$$

$$\left(mc_v \ln \frac{T_2}{T_1} - mR \ln \frac{V_2}{V_1} \right)_{\text{source}} + 0 + \left(mc_p \ln \frac{T_2}{T_1} - mR \ln \frac{P_2}{P_1} \right)_{\text{sink}} = 0$$

$$\ln \frac{T_2}{T_{1A}} + \frac{c_p}{c_v} \ln \frac{T_2}{T_{1B}} = 0 \longrightarrow \frac{T_2}{T_{1A}} \left(\frac{T_2}{T_{1B}} \right)^k = 1 \longrightarrow T_2 = (T_{1A} T_{1B}^k)^{1/(k+1)}$$

where T_{1A} and T_{1B} are the initial temperatures of the source and the sink, respectively, and T_2 is the common final temperature. Therefore, the final temperature of the tanks for maximum power production is

$$T_2 = \left((600 \text{ K})(280 \text{ K})^{1.4} \right)^{\frac{1}{2.4}} = \mathbf{384.7 \text{ K}}$$

Source:

$$-Q_{\text{source,out}} = \Delta U = mc_v(T_2 - T_{1A}) \rightarrow Q_{\text{source,out}} = mc_v(T_{1A} - T_2)$$

$$Q_{\text{source,out}} = mc_v(T_{1A} - T_2) = (40 \text{ kg})(0.718 \text{ kJ/kg}\cdot\text{K})(600 - 384.7)\text{K} = 6184 \text{ kJ}$$

Sink:

$$Q_{\text{sink,in}} - W_{\text{b,out}} = \Delta U \rightarrow Q_{\text{sink,in}} = \Delta H = mc_p(T_2 - T_{1A})$$

$$Q_{\text{sink,in}} = mc_p(T_2 - T_{1A}) = (40 \text{ kg})(1.005 \text{ kJ/kg}\cdot\text{K})(384.7 - 280)\text{K} = 4208 \text{ kJ}$$

Then the work produced becomes

$$W_{\text{max,out}} = Q_H - Q_L = Q_{\text{source,out}} - Q_{\text{sink,in}} = 6184 - 4208 = \mathbf{1977 \text{ kJ}}$$

Therefore, a maximum of 1977 kJ of work can be produced during this process.

8-125E Large brass plates are heated in an oven at a rate of 175/min. The rate of heat transfer to the plates in the oven and the rate of exergy destruction associated with this heat transfer process are to be determined.

Assumptions 1 The thermal properties of the plates are constant. 2 The changes in kinetic and potential energies are negligible. 3 The environment temperature is 75°F.

Properties The density and specific heat of the brass are given to be $\rho = 532.5 \text{ lbm/ft}^3$ and $c_p = 0.091 \text{ Btu/lbm}\cdot\text{°F}$.

Analysis We take the plate to be the system. The energy balance for this closed system can be expressed as

$$\underbrace{E_{\text{in}} - E_{\text{out}}}_{\substack{\text{Net energy transfer} \\ \text{by heat, work, and mass}}} = \underbrace{\Delta E_{\text{system}}}_{\substack{\text{Change in internal, kinetic,} \\ \text{potential, etc. energies}}} \\ Q_{\text{in}} = \Delta U_{\text{plate}} = m(u_2 - u_1) = mc(T_2 - T_1)$$

The mass of each plate and the amount of heat transfer to each plate is

$$m = \rho V = \rho LA = (532.5 \text{ lbm/ft}^3)[(1.5/12 \text{ ft})(1 \text{ ft})(3 \text{ ft})] = 199.7 \text{ lb}$$

$$Q_{\text{in}} = mc(T_2 - T_1) = (199.7 \text{ lbm/plate})(0.091 \text{ Btu/lbm}\cdot\text{°F})(1000 - 75)\text{°F} = 16,809 \text{ Btu/plate}$$

Then the total rate of heat transfer to the plates becomes

$$\dot{Q}_{\text{total}} = \dot{n}_{\text{plate}} Q_{\text{in, per plate}} = (175 \text{ plates/min}) \times (16,809 \text{ Btu/plate}) = 2,941,575 \text{ Btu/min} = \mathbf{49,025 \text{ Btu/s}}$$

We again take a single plate as the system. The entropy generated during this process can be determined by applying an entropy balance on an *extended system* that includes the plate and its immediate surroundings so that the boundary temperature of the extended system is at 1300°F at all times:

$$\underbrace{S_{\text{in}} - S_{\text{out}}}_{\substack{\text{Net entropy transfer} \\ \text{by heat and mass}}} + \underbrace{S_{\text{gen}}}_{\substack{\text{Entropy} \\ \text{generation}}} = \underbrace{\Delta S_{\text{system}}}_{\substack{\text{Change} \\ \text{in entropy}}} \\ \frac{Q_{\text{in}}}{T_b} + S_{\text{gen}} = \Delta S_{\text{system}} \rightarrow S_{\text{gen}} = -\frac{Q_{\text{in}}}{T_b} + \Delta S_{\text{system}}$$

where

$$\Delta S_{\text{system}} = m(s_2 - s_1) = mc_{\text{avg}} \ln \frac{T_2}{T_1} = (199.7 \text{ lbm})(0.091 \text{ Btu/lbm}\cdot\text{R}) \ln \frac{(1000 + 460) \text{ R}}{(75 + 460) \text{ R}} = 18.24 \text{ Btu/R}$$

Substituting,

$$S_{\text{gen}} = -\frac{Q_{\text{in}}}{T_b} + \Delta S_{\text{system}} = -\frac{16,809 \text{ Btu}}{1300 + 460 \text{ R}} + 18.24 \text{ Btu/R} = 8.692 \text{ Btu/R (per plate)}$$

Then the rate of entropy generation becomes

$$\dot{S}_{\text{gen}} = S_{\text{gen}} \dot{n}_{\text{plate}} = (8.692 \text{ Btu/R} \cdot \text{plate})(175 \text{ plates/min}) = 1521 \text{ Btu/min}\cdot\text{R} = 25.35 \text{ Btu/s}\cdot\text{R}$$

The exergy destroyed during a process can be determined from an exergy balance or directly from its definition $X_{\text{destroyed}} = T_0 S_{\text{gen}}$,

$$\dot{X}_{\text{destroyed}} = T_0 \dot{S}_{\text{gen}} = (535 \text{ R})(25.35 \text{ Btu/s}\cdot\text{R}) = \mathbf{13,560 \text{ Btu/s}}$$

8-126 A regenerator is considered to save heat during the cooling of milk in a dairy plant. The amounts of fuel and money such a generator will save per year and the rate of exergy destruction within the regenerator are to be determined.

Assumptions 1 Steady operating conditions exist. 2 The properties of the milk are constant. 5 The environment temperature is 18°C.

Properties The average density and specific heat of milk can be taken to be $\rho_{\text{milk}} \cong \rho_{\text{water}} = 1 \text{ kg/L}$ and $c_{p,\text{milk}} = 3.79 \text{ kJ/kg}\cdot^\circ\text{C}$ (Table A-3).

Analysis The mass flow rate of the milk is

$$\dot{m}_{\text{milk}} = \rho \dot{V}_{\text{milk}} = (1 \text{ kg/L})(12 \text{ L/s}) = 12 \text{ kg/s} = 43,200 \text{ kg/h}$$

Taking the pasteurizing section as the system, the energy balance for this steady-flow system can be expressed in the rate form as

$$\underbrace{\dot{E}_{\text{in}} - \dot{E}_{\text{out}}}_{\text{Rate of net energy transfer by heat, work, and mass}} = \underbrace{\Delta \dot{E}_{\text{system}}}_{\text{Rate of change in internal, kinetic, potential, etc. energies}} \stackrel{\text{no (steady)}}{=} 0 \rightarrow \dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\dot{Q}_{\text{in}} + \dot{m}h_1 = \dot{m}h_2 \quad (\text{since } \Delta ke \cong \Delta pe \cong 0)$$

$$\dot{Q}_{\text{in}} = \dot{m}_{\text{milk}} c_p (T_2 - T_1)$$

Therefore, to heat the milk from 4 to 72°C as being done currently, heat must be transferred to the milk at a rate of

$$\dot{Q}_{\text{current}} = [\dot{m}c_p (T_{\text{pasteurization}} - T_{\text{refrigeration}})]_{\text{milk}} = (12 \text{ kg/s})(3.79 \text{ kJ/kg}\cdot^\circ\text{C})(72 - 4)^\circ\text{C} = 3093 \text{ kJ/s}$$

The proposed regenerator has an effectiveness of $\varepsilon = 0.82$, and thus it will save 82 percent of this energy. Therefore,

$$\dot{Q}_{\text{saved}} = \varepsilon \dot{Q}_{\text{current}} = (0.82)(3093 \text{ kJ/s}) = 2536 \text{ kJ/s}$$

Noting that the boiler has an efficiency of $\eta_{\text{boiler}} = 0.82$, the energy savings above correspond to fuel savings of

$$\text{Fuel Saved} = \frac{\dot{Q}_{\text{saved}}}{\eta_{\text{boiler}}} = \frac{(2536 \text{ kJ/s})}{(0.82)} \frac{(1 \text{ therm})}{(105,500 \text{ kJ})} = 0.02931 \text{ therm/s}$$

Noting that 1 year = 365×24=8760 h and unit cost of natural gas is \$1.04/therm, the annual fuel and money savings will be

$$\text{Fuel Saved} = (0.02931 \text{ therms/s})(8760 \times 3600 \text{ s}) = \mathbf{924,450 \text{ therms/yr}}$$

$$\text{Money saved} = (\text{Fuel saved})(\text{Unit cost of fuel}) = (924,450 \text{ therm/yr})(\$1.30/\text{therm}) = \mathbf{\$1,201,800\text{yr}}$$

The rate of entropy generation during this process is determined by applying the rate form of the entropy balance on an *extended system* that includes the regenerator and the immediate surroundings so that the boundary temperature is the surroundings temperature, which we take to be the cold water temperature of 18°C.

$$\underbrace{\dot{S}_{\text{in}} - \dot{S}_{\text{out}}}_{\text{Rate of net entropy transfer by heat and mass}} + \underbrace{\dot{S}_{\text{gen}}}_{\text{Rate of entropy generation}} = \underbrace{\Delta \dot{S}_{\text{system}}}_{\text{Rate of change of entropy}} \stackrel{\text{no (steady)}}{=} 0 \rightarrow \dot{S}_{\text{gen}} = \dot{S}_{\text{out}} - \dot{S}_{\text{in}}$$

Disregarding entropy transfer associated with fuel flow, the only significant difference between the two cases is the reduction in the entropy transfer to water due to the reduction in heat transfer to water, and is determined to be

$$\dot{S}_{\text{gen, reduction}} = \dot{S}_{\text{out, reduction}} = \frac{\dot{Q}_{\text{out, reduction}}}{T_{\text{surr}}} = \frac{\dot{Q}_{\text{saved}}}{T_{\text{surr}}} = \frac{2536 \text{ kJ/s}}{18 + 273} = 8.715 \text{ kW/K}$$

$$S_{\text{gen, reduction}} = \dot{S}_{\text{gen, reduction}} \Delta t = (8.715 \text{ kJ/s}\cdot\text{K})(8760 \times 3600 \text{ s/year}) = 2.75 \times 10^8 \text{ kJ/K (per year)}$$

The exergy destroyed during a process can be determined from an exergy balance or directly from its definition $X_{\text{destroyed}} = T_0 S_{\text{gen}}$,

$$X_{\text{destroyed, reduction}} = T_0 S_{\text{gen, reduction}} = (291 \text{ K})(2.75 \times 10^8 \text{ kJ/K}) = \mathbf{8.00 \times 10^{10} \text{ kJ (per year)}}$$

8-127 Exhaust gases are expanded in a turbine, which is not well-insulated. The actual and reversible power outputs, the exergy destroyed, and the second-law efficiency are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Potential energy change is negligible. 3 Air is an ideal gas with constant specific heats.

Properties The gas constant of air is $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ and the specific heat of air at the average temperature of $(627+527)/2 = 577^\circ\text{C} = 850 \text{ K}$ is $c_p = 1.11 \text{ kJ/kg}\cdot^\circ\text{C}$ (Table A-2).

Analysis (a) The enthalpy and entropy changes of air across the turbine are

$$\Delta h = c_p (T_2 - T_1) = (1.11 \text{ kJ/kg}\cdot^\circ\text{C})(527 - 627)^\circ\text{C} = -111 \text{ kJ/kg}$$

$$\begin{aligned} \Delta s &= c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \\ &= (1.11 \text{ kJ/kg}\cdot\text{K}) \ln \frac{(527 + 273) \text{ K}}{(627 + 273) \text{ K}} - (0.287 \text{ kJ/kg}\cdot\text{K}) \ln \frac{500 \text{ kPa}}{1200 \text{ kPa}} \\ &= 0.1205 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

The actual and reversible power outputs from the turbine are

$$-\dot{W}_{a,\text{out}} = \dot{m}\Delta h + \dot{Q}_{\text{out}} = (2.5 \text{ kg/s})(-111 \text{ kJ/kg}) + 20 \text{ kW} = \mathbf{-257.5 \text{ kW}}$$

$$-\dot{W}_{\text{rev},\text{out}} = \dot{m}(\Delta h - T_0 \Delta s) = (2.5 \text{ kg/s})(111 \text{ kJ/kg}) - (25 + 273 \text{ K})(0.1205 \text{ kJ/kg}\cdot\text{K}) = \mathbf{-367.3 \text{ kW}}$$

or

$$\dot{W}_{a,\text{out}} = \mathbf{257.5 \text{ kW}}$$

$$\dot{W}_{\text{rev},\text{out}} = \mathbf{367.3 \text{ kW}}$$

(b) The exergy destroyed in the turbine is

$$\dot{X}_{\text{dest}} = \dot{W}_{\text{rev}} - \dot{W}_a = 367.3 - 257.5 = \mathbf{109.8 \text{ kW}}$$

(c) The second-law efficiency is

$$\eta_{\text{II}} = \frac{\dot{W}_a}{\dot{W}_{\text{rev}}} = \frac{257.5 \text{ kW}}{367.3 \text{ kW}} = 0.701 = \mathbf{70.1\%}$$

8-128 Refrigerant-134a is compressed in an adiabatic compressor, whose second-law efficiency is given. The actual work input, the isentropic efficiency, and the exergy destruction are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) The properties of the refrigerant at the inlet of the compressor are (Tables A-11 through A-13)

$$\begin{aligned} T_{\text{sat}@120\text{kPa}} &= -22.32^\circ\text{C} \\ P_1 &= 120\text{ kPa} \\ T_1 &= (-22.32 + 2.3)^\circ\text{C} = -20^\circ\text{C} \end{aligned} \left. \begin{array}{l} h_1 = 238.84\text{ kJ/kg} \\ s_1 = 0.95523\text{ kJ/kg}\cdot\text{K} \end{array} \right\}$$

The enthalpy at the exit for if the process was isentropic is

$$\begin{aligned} P_2 &= 0.7\text{ MPa} \\ s_2 &= s_1 = 0.95523\text{ kJ/kg}\cdot\text{K} \end{aligned} \left. \begin{array}{l} h_{2s} = 275.79\text{ kJ/kg} \end{array} \right\}$$

The expressions for actual and reversible works are

$$\begin{aligned} w_a &= h_2 - h_1 = (h_2 - 238.84)\text{kJ/kg} \\ w_{\text{rev}} &= h_2 - h_1 - T_0(s_2 - s_1) = (h_2 - 238.84)\text{kJ/kg} - (25 + 273\text{ K})(s_2 - 0.95523)\text{kJ/kg}\cdot\text{K} \end{aligned}$$

Substituting these into the expression for the second-law efficiency

$$\eta_{\text{II}} = \frac{w_{\text{rev}}}{w_a} \rightarrow 0.85 = \frac{h_2 - 238.84 - (298)(s_2 - 0.95523)}{h_2 - 238.84}$$

The exit pressure is given (1 MPa). We need one more property to fix the exit state. By a trial-error approach or using EES, we obtain the exit temperature to be 44.14°C . The corresponding enthalpy and entropy values satisfying this equation are

$$\begin{aligned} h_2 &= 282.72\text{ kJ/kg} \\ s_2 &= 0.9773\text{ kJ/kg}\cdot\text{K} \end{aligned}$$

Then,

$$\begin{aligned} w_a &= h_2 - h_1 = 282.72 - 238.84 = \mathbf{43.88\text{kJ/kg}} \\ w_{\text{rev}} &= h_2 - h_1 - T_0(s_2 - s_1) = (282.72 - 238.84)\text{kJ/kg} - (25 + 273\text{ K})(0.9773 - 0.95523)\text{kJ/kg}\cdot\text{K} = 37.30\text{ kJ/kg} \end{aligned}$$

(b) The isentropic efficiency is determined from its definition

$$\eta_s = \frac{h_{2s} - h_1}{h_2 - h_1} = \frac{(275.79 - 238.84)\text{kJ/kg}}{(282.72 - 238.84)\text{kJ/kg}} = 0.842 = \mathbf{84.2\%}$$

(b) The exergy destroyed in the compressor is

$$x_{\text{dest}} = w_a - w_{\text{rev}} = 43.88 - 37.30 = \mathbf{6.58\text{kJ/kg}}$$

8-129 The isentropic efficiency of a water pump is specified. The actual power output, the rate of frictional heating, the exergy destruction, and the second-law efficiency are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) Using saturated liquid properties at the given temperature for the inlet state (Table A-4)

$$T_1 = 30^\circ\text{C} \left\{ \begin{array}{l} h_1 = 125.82 \text{ kJ/kg} \\ s_1 = 0.4367 \text{ kJ/kg}\cdot\text{K} \\ x_1 = 0 \end{array} \right. \left. \vphantom{T_1} \right\} \nu_1 = 0.001004 \text{ m}^3/\text{kg}$$

The power input if the process was isentropic is

$$\dot{W}_s = \dot{m}\nu_1(P_2 - P_1) = (1.35 \text{ kg/s})(0.001004 \text{ m}^3/\text{kg})(4000 - 100)\text{kPa} = 5.288 \text{ kW}$$

Given the isentropic efficiency, the actual power may be determined to be

$$\dot{W}_a = \frac{\dot{W}_s}{\eta_s} = \frac{5.288 \text{ kW}}{0.70} = \mathbf{7.554 \text{ kW}}$$

(b) The difference between the actual and isentropic works is the frictional heating in the pump

$$\dot{Q}_{\text{frictional}} = \dot{W}_a - \dot{W}_s = 7.554 - 5.288 = \mathbf{2.266 \text{ kW}}$$

(c) The enthalpy at the exit of the pump for the actual process can be determined from

$$\dot{W}_a = \dot{m}(h_2 - h_1) \longrightarrow 7.554 \text{ kW} = (1.35 \text{ kg/s})(h_2 - 125.82)\text{kJ/kg} \longrightarrow h_2 = 131.42 \text{ kJ/kg}$$

The entropy at the exit is

$$\left. \begin{array}{l} P_2 = 4 \text{ MPa} \\ h_2 = 131.42 \text{ kJ/kg} \end{array} \right\} s_2 = 0.4423 \text{ kJ/kg}\cdot\text{K}$$

The reversible power and the exergy destruction are

$$\begin{aligned} \dot{W}_{\text{rev}} &= \dot{m}[h_2 - h_1 - T_0(s_2 - s_1)] \\ &= (1.35 \text{ kg/s})[(131.42 - 125.82)\text{kJ/kg} - (20 + 273 \text{ K})(0.4423 - 0.4367)\text{kJ/kg}\cdot\text{K}] = 5.362 \text{ kW} \end{aligned}$$

$$\dot{X}_{\text{dest}} = \dot{W}_a - \dot{W}_{\text{rev}} = 7.554 - 5.362 = \mathbf{2.193 \text{ kW}}$$

(d) The second-law efficiency is

$$\eta_{\text{II}} = \frac{\dot{W}_{\text{rev}}}{\dot{W}_a} = \frac{5.362 \text{ kW}}{7.554 \text{ kW}} = 0.710 = \mathbf{71.0\%}$$

8-130 Argon gas is expanded adiabatically in an expansion valve. The exergy of argon at the inlet, the exergy destruction, and the second-law efficiency are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are zero. 3 Argon is an ideal gas with constant specific heats.

Properties The properties of argon gas are $R = 0.2081 \text{ kJ/kg}\cdot\text{K}$, $c_p = 0.5203 \text{ kJ/kg}\cdot^\circ\text{C}$ (Table A-2).

Analysis (a) The exergy of the argon at the inlet is

$$\begin{aligned}\psi_1 &= h_1 - h_0 - T_0(s_1 - s_0) \\ &= c_p(T_1 - T_0) - T_0 \left[c_p \ln \frac{T_1}{T_0} - R \ln \frac{P_1}{P_0} \right] \\ &= (0.5203 \text{ kJ/kg}\cdot\text{K})(100 - 25)^\circ\text{C} - (298 \text{ K}) \left[(0.5203 \text{ kJ/kg}\cdot\text{K}) \ln \frac{373 \text{ K}}{298 \text{ K}} - (0.2081 \text{ kJ/kg}\cdot\text{K}) \ln \frac{3500 \text{ kPa}}{100 \text{ kPa}} \right] \\ &= \mathbf{224.7 \text{ kJ/kg}}\end{aligned}$$

(b) Noting that the temperature remains constant in a throttling process of an ideal gas, the exergy destruction is determined from

$$\begin{aligned}x_{\text{dest}} &= T_0 s_{\text{gen}} \\ &= T_0(s_2 - s_1) \\ &= T_0 \left(-R \ln \frac{P_1}{P_0} \right) = (298 \text{ K}) \left[- (0.2081 \text{ kJ/kg}\cdot\text{K}) \ln \left(\frac{500 \text{ kPa}}{3500 \text{ kPa}} \right) \right] \\ &= \mathbf{120.7 \text{ kJ/kg}}\end{aligned}$$

(c) The second-law efficiency can be determined from

$$\eta_{\text{II}} = \frac{x_{\text{recovered}}}{x_{\text{expended}}} = \frac{0}{\psi_1 - \psi_2} = \frac{0 \text{ kJ/kg}}{(224.7 - 104.0) \text{ kJ/kg}} = 0 = \mathbf{0\%}$$

where

$$\psi_2 = \psi_1 - x_{\text{dest}} = [224.7 - (224.7 - 120.7)] \text{ kJ/kg} = 104.0 \text{ kJ/kg}$$

Discussion An alternative (and different) definition for the second-law efficiency of an expansion valve can be expressed using an “exergy out/exergy in” approach as

$$\eta_{\text{II}} = \frac{x_{\text{out}}}{x_{\text{in}}} = \frac{\psi_2}{\psi_1} = \frac{104.0 \text{ kJ/kg}}{224.7 \text{ kJ/kg}} = 0.463 = 46.3\%$$

Note that an expansion valve is a very wasteful device and it destroys all of the exergy expended in the process. Therefore, we prefer the first approach for the calculation of second-law efficiency.

8-131 Heat is lost from the air flowing in a diffuser. The exit temperature, the rate of exergy destruction, and the second law efficiency are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Potential energy change is negligible. 3 Nitrogen is an ideal gas with variable specific heats.

Properties The gas constant of nitrogen is $R = 0.2968 \text{ kJ/kg}\cdot\text{K}$.

Analysis (a) For this problem, we use the properties from EES software. Remember that for an ideal gas, enthalpy is a function of temperature only whereas entropy is functions of both temperature and pressure. At the inlet of the diffuser and at the dead state, we have

$$\left. \begin{array}{l} T_1 = 110^\circ\text{C} = 383 \text{ K} \\ P_1 = 100 \text{ kPa} \end{array} \right\} \begin{array}{l} h_1 = 88.39 \text{ kJ/kg} \\ s_1 = 7.101 \text{ kJ/kg}\cdot\text{K} \end{array}$$

$$\left. \begin{array}{l} T_0 = 300 \text{ K} \\ P_0 = 100 \text{ kPa} \end{array} \right\} \begin{array}{l} h_0 = 1.93 \text{ kJ/kg} \\ s_0 = 6.846 \text{ kJ/kg}\cdot\text{K} \end{array}$$

An energy balance on the diffuser gives

$$h_1 + \frac{V_1^2}{2} = h_2 + \frac{V_2^2}{2} + q_{\text{out}}$$

$$88.39 \text{ kJ/kg} + \frac{(205 \text{ m/s})^2}{2} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = h_2 + \frac{(45 \text{ m/s})^2}{2} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) + 2.5 \text{ kJ/kg}$$

$$\longrightarrow h_2 = 105.9 \text{ kJ/kg}$$

The corresponding properties at the exit of the diffuser are

$$\left. \begin{array}{l} h_2 = 105.9 \text{ kJ/kg} \\ P_2 = 110 \text{ kPa} \end{array} \right\} \begin{array}{l} T_2 = \mathbf{127^\circ\text{C}} = 400 \text{ K} \\ s_2 = 7.117 \text{ kJ/kg}\cdot\text{K} \end{array}$$

(b) The mass flow rate of the nitrogen is determined to be

$$\dot{m} = \rho_2 A_2 V_2 = \frac{P_2}{RT_2} A_2 V_2 = \frac{110 \text{ kPa}}{(0.2968 \text{ kJ/kg}\cdot\text{K})(400 \text{ K})} (0.04 \text{ m}^2)(45 \text{ m/s}) = 1.669 \text{ kg/s}$$

The exergy destruction in the nozzle is the exergy difference between the inlet and exit of the diffuser:

$$\dot{X}_{\text{dest}} = \dot{m} \left[h_1 - h_2 + \frac{V_1^2 - V_2^2}{2} - T_0 (s_1 - s_2) \right]$$

$$= (1.669 \text{ kg/s}) \left[(88.39 - 105.9) \text{ kJ/kg} + \frac{(205 \text{ m/s})^2 - (45 \text{ m/s})^2}{2} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) - (300 \text{ K})(7.101 - 7.117) \text{ kJ/kg}\cdot\text{K} \right] = \mathbf{12.4 \text{ kW}}$$

(c) The second-law efficiency for this device may be defined as the exergy output divided by the exergy input:

$$\dot{X}_1 = \dot{m} \left[h_1 - h_0 + \frac{V_1^2}{2} - T_0 (s_1 - s_0) \right]$$

$$= (1.669 \text{ kg/s}) \left[(88.39 - 1.93) \text{ kJ/kg} + \frac{(205 \text{ m/s})^2}{2} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) - (300 \text{ K})(7.101 - 6.846) \text{ kJ/kg}\cdot\text{K} \right]$$

$$= 51.96 \text{ kW}$$

$$\eta_{\text{II}} = \frac{\dot{X}_2}{\dot{X}_1} = 1 - \frac{\dot{X}_{\text{dest}}}{\dot{X}_1} = 1 - \frac{12.4 \text{ kW}}{51.96 \text{ kW}} = 0.761 = \mathbf{76.1\%}$$

8-132 A relation for the second-law efficiency of a heat engine operating between a heat source and a heat sink at specified temperatures is to be obtained.

Analysis The second-law efficiency is defined as the ratio of the availability (exergy) recovered to availability supplied during a process. The work W produced is the availability recovered. The decrease in the availability of the heat supplied Q_H is the availability supplied or invested.

Therefore,

$$\eta_{II} = \frac{W}{\left(1 - \frac{T_0}{T_H}\right)Q_H - \left(1 - \frac{T_0}{T_L}\right)Q_L}$$

Note that the first term in the denominator is the availability of heat supplied to the heat engine whereas the second term is the availability of the heat rejected by the heat engine. The difference between the two is the availability expended during the process.

8-133 Writing energy and entropy balances, a relation for the reversible work is to be obtained for a closed system that exchanges heat with surroundings at T_0 in the amount of Q_0 as well as a heat reservoir at temperature T_R in the amount Q_R .

Assumptions Kinetic and potential changes are negligible.

Analysis We take the direction of heat transfers to be to the system (heat input) and the direction of work transfer to be from the system (work output). The result obtained is still general since quantities with opposite directions can be handled the same way by using negative signs. The energy and entropy balances for this stationary closed system can be expressed as

$$\text{Energy balance: } E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}} \rightarrow Q_0 + Q_R - W = U_2 - U_1 \longrightarrow W = U_1 - U_2 + Q_0 + Q_R \quad (1)$$

$$\text{Entropy balance: } S_{\text{in}} - S_{\text{out}} + S_{\text{gen}} = \Delta S_{\text{system}} \rightarrow S_{\text{gen}} = (S_2 - S_1) + \frac{-Q_R}{T_R} + \frac{-Q_0}{T_0} \quad (2)$$

Solving for Q_0 from (2) and substituting in (1) yields

$$W = (U_1 - U_2) - T_0(S_1 - S_2) - Q_R \left(1 - \frac{T_0}{T_R}\right) - T_0 S_{\text{gen}}$$

The useful work relation for a closed system is obtained from

$$\begin{aligned} W_u &= W - W_{\text{surr}} \\ &= (U_1 - U_2) - T_0(S_1 - S_2) - Q_R \left(1 - \frac{T_0}{T_R}\right) - T_0 S_{\text{gen}} - P_0(V_2 - V_1) \end{aligned}$$

Then the reversible work relation is obtained by substituting $S_{\text{gen}} = 0$,

$$W_{\text{rev}} = (U_1 - U_2) - T_0(S_1 - S_2) + P_0(V_1 - V_2) - Q_R \left(1 - \frac{T_0}{T_R}\right)$$

A positive result for W_{rev} indicates work output, and a negative result work input. Also, the Q_R is a positive quantity for heat transfer to the system, and a negative quantity for heat transfer from the system.

8-134 Writing energy and entropy balances, a relation for the reversible work is to be obtained for a steady-flow system that exchanges heat with surroundings at T_0 at a rate of \dot{Q}_0 as well as a heat reservoir at temperature T_R in the amount \dot{Q}_R .

Analysis We take the direction of heat transfers to be to the system (heat input) and the direction of work transfer to be from the system (work output). The result obtained is still general since quantities with opposite directions can be handled the same way by using negative signs. The energy and entropy balances for this stationary closed system can be expressed as

Energy balance: $\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \rightarrow \dot{E}_{\text{in}} = \dot{E}_{\text{out}}$

$$\dot{Q}_0 + \dot{Q}_R - \dot{W} = \sum \dot{m}_e \left(h_e + \frac{V_e^2}{2} + gz_e \right) - \sum \dot{m}_i \left(h_i + \frac{V_i^2}{2} + gz_i \right)$$

or
$$\dot{W} = \sum \dot{m}_i \left(h_i + \frac{V_i^2}{2} + gz_i \right) - \sum \dot{m}_e \left(h_e + \frac{V_e^2}{2} + gz_e \right) + \dot{Q}_0 + \dot{Q}_R \quad (1)$$

Entropy balance:

$$\dot{S}_{\text{in}} - \dot{S}_{\text{out}} + \dot{S}_{\text{gen}} = \Delta \dot{S}_{\text{system}} = 0$$

$$\dot{S}_{\text{gen}} = \dot{S}_{\text{out}} - \dot{S}_{\text{in}}$$

$$\dot{S}_{\text{gen}} = \sum \dot{m}_e s_e - \sum \dot{m}_i s_i + \frac{-\dot{Q}_R}{T_R} + \frac{-\dot{Q}_0}{T_0} \quad (2)$$

Solving for \dot{Q}_0 from (2) and substituting in (1) yields

$$\dot{W} = \sum \dot{m}_i \left(h_i + \frac{V_i^2}{2} + gz_i - T_0 s_i \right) - \sum \dot{m}_e \left(h_e + \frac{V_e^2}{2} + gz_e - T_0 s_e \right) - T_0 \dot{S}_{\text{gen}} - \dot{Q}_R \left(1 - \frac{T_0}{T_R} \right)$$

Then the reversible work relation is obtained by substituting $\dot{S}_{\text{gen}} = 0$,

$$\dot{W}_{\text{rev}} = \sum \dot{m}_i \left(h_i + \frac{V_i^2}{2} + gz_i - T_0 s_i \right) - \sum \dot{m}_e \left(h_e + \frac{V_e^2}{2} + gz_e - T_0 s_e \right) - \dot{Q}_R \left(1 - \frac{T_0}{T_R} \right)$$

A positive result for \dot{W}_{rev} indicates work output, and a negative result work input. Also, the \dot{Q}_R is a positive quantity for heat transfer to the system, and a negative quantity for heat transfer from the system.

8-135 Writing energy and entropy balances, a relation for the reversible work is to be obtained for a uniform-flow system that exchanges heat with surroundings at T_0 in the amount of Q_0 as well as a heat reservoir at temperature T_R in the amount Q_R .

Assumptions Kinetic and potential changes are negligible.

Analysis We take the direction of heat transfers to be to the system (heat input) and the direction of work transfer to be from the system (work output). The result obtained is still general since quantities with opposite directions can be handled the same way by using negative signs. The energy and entropy balances for this stationary closed system can be expressed as

Energy balance: $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$

$$Q_0 + Q_R - W = \sum m_e \left(h_e + \frac{V_e^2}{2} + gz_e \right) - \sum m_i \left(h_i + \frac{V_i^2}{2} + gz_i \right) + (U_2 - U_1)_{\text{cv}}$$

or,
$$W = \sum m_i \left(h_i + \frac{V_i^2}{2} + gz_i \right) - \sum m_e \left(h_e + \frac{V_e^2}{2} + gz_e \right) - (U_2 - U_1)_{\text{cv}} + Q_0 + Q_R \quad (1)$$

Entropy balance: $S_{\text{in}} - S_{\text{out}} + S_{\text{gen}} = \Delta S_{\text{system}}$

$$S_{\text{gen}} = (S_2 - S_1)_{\text{cv}} + \sum m_e s_e - \sum m_i s_i + \frac{-Q_R}{T_R} + \frac{-Q_0}{T_0} \quad (2)$$

Solving for Q_0 from (2) and substituting in (1) yields

$$W = \sum m_i \left(h_i + \frac{V_i^2}{2} + gz_i - T_0 s_i \right) - \sum m_e \left(h_e + \frac{V_e^2}{2} + gz_e - T_0 s_e \right) + [(U_1 - U_2) - T_0 (S_1 - S_2)]_{\text{cv}} - T_0 S_{\text{gen}} - Q_R \left(1 - \frac{T_0}{T_R} \right)$$

The useful work relation for a closed system is obtained from

$$W_u = W - W_{\text{surr}} = \sum m_i \left(h_i + \frac{V_i^2}{2} + gz_i - T_0 s_i \right) - \sum m_e \left(h_e + \frac{V_e^2}{2} + gz_e - T_0 s_e \right) + [(U_1 - U_2) - T_0 (S_1 - S_2)]_{\text{cv}} - T_0 S_{\text{gen}} - Q_R \left(1 - \frac{T_0}{T_R} \right) - P_0 (V_2 - V_1)$$

Then the reversible work relation is obtained by substituting $S_{\text{gen}} = 0$,

$$W_{\text{rev}} = \sum m_i \left(h_i + \frac{V_i^2}{2} + gz_i - T_0 s_i \right) - \sum m_e \left(h_e + \frac{V_e^2}{2} + gz_e - T_0 s_e \right) + [(U_1 - U_2) - T_0 (S_1 - S_2) + P_0 (V_1 - V_2)]_{\text{cv}} - Q_R \left(1 - \frac{T_0}{T_R} \right)$$

A positive result for W_{rev} indicates work output, and a negative result work input. Also, the Q_R is a positive quantity for heat transfer to the system, and a negative quantity for heat transfer from the system.

Fundamentals of Engineering (FE) Exam Problems

8-136 Heat is lost through a plane wall steadily at a rate of 800 W. If the inner and outer surface temperatures of the wall are 20°C and 5°C, respectively, and the environment temperature is 0°C, the rate of exergy destruction within the wall is

- (a) 40 W (b) 17,500 W (c) 765 W (d) 32,800 W (e) 0 W

Answer (a) 40 W

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
Q=800 "W"

W4_ex=0 "Taking the exergy content to be zero"
```

8-142 Keeping the limitations imposed by the second-law of thermodynamics in mind, choose the wrong statement below:

- (a) A heat engine cannot have a thermal efficiency of 100%.
- (b) For all reversible processes, the second-law efficiency is 100%.
- (c) The second-law efficiency of a heat engine cannot be greater than its thermal efficiency.
- (d) The second-law efficiency of a process is 100% if no entropy is generated during that process.
- (e) The coefficient of performance of a refrigerator can be greater than 1.

Answer (c) The second-law efficiency of a heat engine cannot be greater than its thermal efficiency.

8-143 A furnace can supply heat steadily at a 1300 K at a rate of 500 kJ/s. The maximum amount of power that can be produced by using the heat supplied by this furnace in an environment at 300 K is

- (a) 115 kW
- (b) 192 kW
- (c) 385 kW
- (d) 500 kW
- (e) 650 kW

Answer (c) 385 kW

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

Actual and Ideal Cycles, Carnot cycle, Air-Standard Assumptions, Reciprocating Engines

9-1C The air standard assumptions are: (1) the working fluid is air which behaves as an ideal gas, (2) all the processes are internally reversible, (3) the combustion process is replaced by the heat addition process, and (4) the exhaust process is replaced by the heat rejection process which returns the working fluid to its original state.

9-2C The cold air standard assumptions involves the additional assumption that air can be treated as an ideal gas with constant specific heats at room temperature.

9-3C It is less than the thermal efficiency of a Carnot cycle.

9-4C It represents the net work on both diagrams.

9-5C It is the ratio of the maximum to minimum volumes in the cylinder.

9-6C The MEP is the fictitious pressure which, if acted on the piston during the entire power stroke, would produce the same amount of net work as that produced during the actual cycle.

9-7C Yes.

9-8C Assuming no accumulation of carbon deposits on the piston face, the compression ratio will remain the same (otherwise it will increase). The mean effective pressure, on the other hand, will decrease as a car gets older as a result of wear and tear.

9-9C The SI and CI engines differ from each other in the way combustion is initiated; by a spark in SI engines, and by compressing the air above the self-ignition temperature of the fuel in CI engines.

9-10C Stroke is the distance between the TDC and the BDC, bore is the diameter of the cylinder, TDC is the position of the piston when it forms the smallest volume in the cylinder, and clearance volume is the minimum volume formed in the cylinder.

9-11E The maximum possible thermal efficiency of a gas power cycle with specified reservoirs is to be determined.

Analysis The maximum efficiency this cycle can have is

$$\eta_{\text{th,Carnot}} = 1 - \frac{T_L}{T_H} = 1 - \frac{(80 + 460) \text{ R}}{(1100 + 460) \text{ R}} = 0.654 = \mathbf{65.4\%}$$

9-12 The three processes of an air-standard cycle are described. The cycle is to be shown on the P - v and T - s diagrams, and the back work ratio and the thermal efficiency are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Properties The properties of air are given as $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$.

Analysis (a) The P - v and T - s diagrams of the cycle are shown in the figures.

(b) The temperature at state 2 is

$$T_2 = T_1 \frac{P_2}{P_1} = (300 \text{ K}) \frac{700 \text{ kPa}}{100 \text{ kPa}} = 2100 \text{ K}$$

$$T_3 = T_2 = 2100 \text{ K}$$

During process 1-3, we have

$$\begin{aligned} w_{3-1,in} &= -\int_3^1 P d v = -P_1 (v_1 - v_3) = -R(T_1 - T_3) \\ &= -(0.287 \text{ kJ/kg}\cdot\text{K})(300 - 2100)\text{K} = 516.6 \text{ kJ/kg} \end{aligned}$$

During process 2-3, we have

$$\begin{aligned} w_{2-3,out} &= \int_2^3 P d v = \int_2^3 \frac{RT}{v} d v = RT \ln \frac{v_3}{v_2} = RT \ln \frac{7v_2}{v_2} = RT \ln 7 \\ &= (0.287 \text{ kJ/kg}\cdot\text{K})(2100)\text{K} \ln 7 = 1172.8 \text{ kJ/kg} \end{aligned}$$

The back work ratio is then

$$r_{bw} = \frac{w_{3-1,in}}{w_{2-3,out}} = \frac{516.6 \text{ kJ/kg}}{1172.8 \text{ kJ/kg}} = \mathbf{0.440}$$

Heat input is determined from an energy balance on the cycle during process 1-3,

$$\begin{aligned} q_{1-3,in} - w_{2-3,out} &= \Delta u_{1-3} \\ q_{1-3,in} &= \Delta u_{1-3} + w_{2-3,out} \\ &= c_v (T_3 - T_1) + w_{2-3,out} \\ &= (0.718 \text{ kJ/kg}\cdot\text{K})(2100 - 300) + 1172.8 \text{ kJ/kg} \\ &= 2465 \text{ kJ/kg} \end{aligned}$$

The net work output is

$$w_{net} = w_{2-3,out} - w_{3-1,in} = 1172.8 - 516.6 = 656.2 \text{ kJ/kg}$$

(c) The thermal efficiency is then

$$\eta_{th} = \frac{w_{net}}{q_{in}} = \frac{656.2 \text{ kJ}}{2465 \text{ kJ}} = 0.266 = \mathbf{26.6\%}$$

9-13 The four processes of an air-standard cycle are described. The cycle is to be shown on P - v and T - s diagrams, and the net work output and the thermal efficiency are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with variable specific heats.

Properties The properties of air are given in Table A-17.

Analysis (b) The properties of air at various states are

$$T_1 = 295 \text{ K} \longrightarrow \begin{aligned} h_1 &= 295.17 \text{ kJ/kg} \\ P_{r_1} &= 1.3068 \end{aligned}$$

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = \frac{600 \text{ kPa}}{100 \text{ kPa}} (1.3068) = 7.841 \longrightarrow \begin{aligned} u_2 &= 352.29 \text{ kJ/kg} \\ T_2 &= 490.3 \text{ K} \end{aligned}$$

$$T_3 = 1500 \text{ K} \longrightarrow \begin{aligned} u_3 &= 1205.41 \text{ kJ/kg} \\ P_{r_3} &= 601.9 \end{aligned}$$

$$\frac{P_3 v_3}{T_3} = \frac{P_2 v_2}{T_2} \longrightarrow P_3 = \frac{T_3}{T_2} P_2 = \frac{1500 \text{ K}}{490.3 \text{ K}} (600 \text{ kPa}) = 1835.6 \text{ kPa}$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \frac{100 \text{ kPa}}{1835.6 \text{ kPa}} (601.9) = 32.79 \longrightarrow h_4 = 739.71 \text{ kJ/kg}$$

From energy balances,

$$q_{\text{in}} = u_3 - u_2 = 1205.41 - 352.29 = 853.1 \text{ kJ/kg}$$

$$q_{\text{out}} = h_4 - h_1 = 739.71 - 295.17 = 444.5 \text{ kJ/kg}$$

$$w_{\text{net,out}} = q_{\text{in}} - q_{\text{out}} = 853.1 - 444.5 = \mathbf{408.6 \text{ kJ/kg}}$$

(c) Then the thermal efficiency becomes

$$\eta_{\text{th}} = \frac{w_{\text{net,out}}}{q_{\text{in}}} = \frac{408.6 \text{ kJ/kg}}{853.1 \text{ kJ/kg}} = 0.479 = \mathbf{47.9\%}$$

9-14 Problem 9-13 is reconsidered. The effect of the maximum temperature of the cycle on the net work output and thermal efficiency is to be investigated. Also, T - s and P - v diagrams for the cycle are to be plotted.

Analysis Using EES, the problem is solved as follows:

"Input Data"

$T[1]=295$ [K]
 $P[1]=100$ [kPa]
 $P[2] = 600$ [kPa]
 $T[3]=1500$ [K]
 $P[4] = 100$ [kPa]

"Process 1-2 is isentropic compression"

$s[1]=\text{entropy}(\text{air}, T=T[1], P=P[1])$
 $s[2]=s[1]$
 $T[2]=\text{temperature}(\text{air}, s=s[2], P=P[2])$
 $P[2]*v[2]/T[2]=P[1]*v[1]/T[1]$
 $P[1]*v[1]=R*T[1]$
 $R=0.287$ [kJ/kg-K]

"Conservation of energy for process 1 to 2"

$q_{12} - w_{12} = \text{DELTA}u_{12}$
 $q_{12} = 0$ "isentropic process"
 $\text{DELTA}u_{12} = \text{intenergy}(\text{air}, T=T[2]) - \text{intenergy}(\text{air}, T=T[1])$

"Process 2-3 is constant volume heat addition"

$s[3]=\text{entropy}(\text{air}, T=T[3], P=P[3])$
 $\{P[3]*v[3]/T[3]=P[2]*v[2]/T[2]\}$
 $P[3]*v[3]=R*T[3]$
 $v[3]=v[2]$

"Conservation of energy for process 2 to 3"

$q_{23} - w_{23} = \text{DELTA}u_{23}$
 $w_{23} = 0$ "constant volume process"
 $\text{DELTA}u_{23} = \text{intenergy}(\text{air}, T=T[3]) - \text{intenergy}(\text{air}, T=T[2])$

"Process 3-4 is isentropic expansion"

$s[4]=\text{entropy}(\text{air}, T=T[4], P=P[4])$
 $s[4]=s[3]$

 $\{P[4]*v[4]=0.287*T[4]\}$

"Conservation of energy for process 3 to 4"

$q_{34} - w_{34} = \text{DELTA}u_{34}$
 $q_{34} = 0$ "isentropic process"
 $\text{DELTA}u_{34} = \text{intenergy}(\text{air}, T=T[4]) - \text{intenergy}(\text{air}, T=T[3])$

"Process 4-1 is constant pressure heat rejection"

$\{P[4]*v[4]/T[4]=P[1]*v[1]/T[1]\}$

"Conservation of energy for process 4 to 1"

$q_{41} - w_{41} = \text{DELTA}u_{41}$
 $w_{41} = P[1]*(v[1]-v[4])$ "constant pressure process"
 $\text{DELTA}u_{41} = \text{intenergy}(\text{air}, T=T[1]) - \text{intenergy}(\text{air}, T=T[4])$
 $q_{in_total} = q_{23}$

$w_{net} = w_{12} + w_{23} + w_{34} + w_{41}$
 $\text{Eta}_{th} = w_{net}/q_{in_total} * 100$ "Thermal efficiency, in percent"

T_3 [K]	η_{th}	$q_{in,total}$ [kJ/kg]	W_{net} [kJ/kg]
1500	47.91	852.9	408.6
1600	48.31	945.7	456.9
1700	48.68	1040	506.1
1800	49.03	1134	556
1900	49.35	1229	606.7
2000	49.66	1325	658.1
2100	49.95	1422	710.5
2200	50.22	1519	763
2300	50.48	1617	816.1
2400	50.72	1715	869.8
2500	50.95	1813	924

9-15 The three processes of an air-standard cycle are described. The cycle is to be shown on P - v and T - s diagrams, and the heat rejected and the thermal efficiency are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2).

Analysis (b) The temperature at state 2 and the heat input are

$$T_2 = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (300 \text{ K}) \left(\frac{1000 \text{ kPa}}{100 \text{ kPa}} \right)^{0.4/1.4} = 579.2 \text{ K}$$

$$Q_{\text{in}} = m(h_3 - h_2) = mc_p(T_3 - T_2)$$

$$416 \text{ kJ} = (0.5 \text{ kg})(1.005 \text{ kJ/kg}\cdot\text{K})(T_3 - 579.2) \longrightarrow T_3 = 1407.1 \text{ K}$$

Process 3-1 is a straight line on the P - v diagram, thus the w_{31} is simply the area under the process curve,

$$w_{31} = \text{area} = \frac{P_3 + P_1}{2} (v_1 - v_3) = \frac{P_3 + P_1}{2} \left(\frac{RT_1}{P_1} - \frac{RT_3}{P_3} \right)$$

$$= \left(\frac{1000 + 100 \text{ kPa}}{2} \right) \left(\frac{300 \text{ K}}{100 \text{ kPa}} - \frac{1407.1 \text{ K}}{1000 \text{ kPa}} \right) (0.287 \text{ kJ/kg}\cdot\text{K})$$

$$= 251.4 \text{ kJ/kg}$$

Energy balance for process 3-1 gives

$$E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}} \longrightarrow -Q_{31,\text{out}} - W_{31,\text{out}} = m(u_1 - u_3)$$

$$Q_{31,\text{out}} = -mw_{31,\text{out}} - mc_v(T_1 - T_3) = -m[w_{31,\text{out}} + c_v(T_1 - T_3)]$$

$$= -(0.5 \text{ kg})[251.4 + (0.718 \text{ kJ/kg}\cdot\text{K})(300 - 1407.1)\text{K}]$$

$$= \mathbf{271.7 \text{ kJ}}$$

(c) The thermal efficiency is then

$$\eta_{\text{th}} = 1 - \frac{Q_{\text{out}}}{Q_{\text{in}}} = 1 - \frac{271.7 \text{ kJ}}{416 \text{ kJ}} = 0.347 = \mathbf{34.7\%}$$

9-16E The four processes of an air-standard cycle are described. The cycle is to be shown on P - v and T - s diagrams, and the total heat input and the thermal efficiency are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with variable specific heats.

Properties The properties of air are given in Table A-17E.

Analysis (b) The properties of air at various states are

$$T_1 = 540 \text{ R} \longrightarrow u_1 = 92.04 \text{ Btu/lbm}, \quad h_1 = 129.06 \text{ Btu/lbm}$$

$$q_{\text{in},12} = u_2 - u_1 \longrightarrow u_2 = u_1 + q_{\text{in},12} = 92.04 + 300 = 392.04 \text{ Btu/lbm}$$

$$T_2 = 2116 \text{ R}, \quad h_2 = 537.1 \text{ Btu/lbm}$$

$$\frac{P_2 v_2}{T_2} = \frac{P_1 v_1}{T_1} \longrightarrow P_2 = \frac{T_2}{T_1} P_1 = \frac{2116 \text{ R}}{540 \text{ R}} (14.7 \text{ psia}) = 57.6 \text{ psia}$$

$$T_3 = 3200 \text{ R} \longrightarrow h_3 = 849.48 \text{ Btu/lbm}$$

$$P_{r_3} = 1242$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \frac{14.7 \text{ psia}}{57.6 \text{ psia}} (1242) = 317.0 \longrightarrow h_4 = 593.22 \text{ Btu/lbm}$$

From energy balance,

$$q_{23,\text{in}} = h_3 - h_2 = 849.48 - 537.1 = 312.38 \text{ Btu/lbm}$$

$$q_{\text{in}} = q_{12,\text{in}} + q_{23,\text{in}} = 300 + 312.38 = \mathbf{612.38 \text{ Btu/lbm}}$$

$$q_{\text{out}} = h_4 - h_1 = 593.22 - 129.06 = 464.16 \text{ Btu/lbm}$$

(c) Then the thermal efficiency becomes

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{464.16 \text{ Btu/lbm}}{612.38 \text{ Btu/lbm}} = \mathbf{24.2\%}$$

9-17E The four processes of an air-standard cycle are described. The cycle is to be shown on P - v and T - s diagrams, and the total heat input and the thermal efficiency are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 0.240$ Btu/lbm·R, $c_v = 0.171$ Btu/lbm·R, and $k = 1.4$ (Table A-2E).

Analysis (b) The temperature at state 2 and the heat input are

$$q_{in,12} = u_2 - u_1 = c_v(T_2 - T_1)$$

$$300 \text{ Btu/lbm} = (0.171 \text{ Btu/lbm}\cdot\text{R})(T_2 - 540)\text{R}$$

$$T_2 = 2294 \text{ R}$$

$$\frac{P_2 v_2}{T_2} = \frac{P_1 v_1}{T_1} \longrightarrow P_2 = \frac{T_2}{T_1} P_1 = \frac{2294 \text{ R}}{540 \text{ R}} (14.7 \text{ psia}) = 62.46 \text{ psia}$$

$$q_{in,23} = h_3 - h_2 = c_p(T_3 - T_2) = (0.24 \text{ Btu/lbm}\cdot\text{R})(3200 - 2294)\text{R} = 217.4 \text{ Btu/lbm}$$

Process 3-4 is isentropic:

$$T_4 = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = (3200 \text{ R}) \left(\frac{14.7 \text{ psia}}{62.46 \text{ psia}} \right)^{0.4/1.4} = 2117 \text{ R}$$

$$q_{in} = q_{in,12} + q_{in,23} = 300 + 217.4 = \mathbf{517.4 \text{ Btu/lbm}}$$

$$q_{out} = h_4 - h_1 = c_p(T_4 - T_1) = (0.240 \text{ Btu/lbm}\cdot\text{R})(2117 - 540) = 378.5 \text{ Btu/lbm}$$

(c) The thermal efficiency is then

$$\eta_{th} = 1 - \frac{q_{out}}{q_{in}} = 1 - \frac{378.5 \text{ Btu/lbm}}{517.4 \text{ Btu/lbm}} = \mathbf{26.8\%}$$

9-18 A Carnot cycle with specified temperature limits is considered. The maximum pressure in the cycle, the heat transfer to the working fluid, and the mass of the working fluid are to be determined.

Assumptions Air is an ideal gas with variable specific heats.

Analysis (a) In a Carnot cycle, the maximum pressure occurs at the beginning of the expansion process, which is state 1.

$$T_1 = 1200 \text{ K} \quad \longrightarrow \quad P_{r_1} = 238 \quad (\text{Table A-17})$$

$$T_4 = 350 \text{ K} \quad \longrightarrow \quad P_{r_4} = 2.379$$

$$P_1 = \frac{P_{r_1}}{P_{r_4}} P_4 = \frac{238}{2.379} (300 \text{ kPa}) = 30,013 \text{ kPa} \cong \mathbf{30.0 \text{ MPa}} = P_{\max}$$

(b) The heat input is determined from

$$\eta_{\text{th}} = 1 - \frac{T_L}{T_H} = 1 - \frac{350 \text{ K}}{1200 \text{ K}} = 70.83\%$$

$$Q_{\text{in}} = W_{\text{net,out}} / \eta_{\text{th}} = (0.5 \text{ kJ}) / (0.7083) = \mathbf{0.706 \text{ kJ}}$$

(c) The mass of air is

$$s_4 - s_3 = (s_4^\circ - s_3^\circ)^{\phi_0} - R \ln \frac{P_4}{P_3} = -(0.287 \text{ kJ/kg} \cdot \text{K}) \ln \frac{300 \text{ kPa}}{150 \text{ kPa}}$$

$$= -0.199 \text{ kJ/kg} \cdot \text{K} = s_1 - s_2$$

$$w_{\text{net,out}} = (s_2 - s_1)(T_H - T_L) = (0.199 \text{ kJ/kg} \cdot \text{K})(1200 - 350) \text{ K} = 169.15 \text{ kJ/kg}$$

$$m = \frac{W_{\text{net,out}}}{w_{\text{net,out}}} = \frac{0.5 \text{ kJ}}{169.15 \text{ kJ/kg}} = \mathbf{0.00296 \text{ kg}}$$

9-19 A Carnot cycle with specified temperature limits is considered. The maximum pressure in the cycle, the heat transfer to the working fluid, and the mass of the working fluid are to be determined.

Assumptions Helium is an ideal gas with constant specific heats.

Properties The properties of helium at room temperature are $R = 2.0769 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.667$ (Table A-2).

Analysis (a) In a Carnot cycle, the maximum pressure occurs at the beginning of the expansion process, which is state 1.

$$\frac{T_1}{T_4} = \left(\frac{P_1}{P_4} \right)^{(k-1)/k}$$

or,

$$P_1 = P_4 \left(\frac{T_1}{T_4} \right)^{k/(k-1)} = (300 \text{ kPa}) \left(\frac{1200 \text{ K}}{350 \text{ K}} \right)^{1.667/0.667} = \mathbf{6524 \text{ kPa}}$$

(b) The heat input is determined from

$$\eta_{\text{th}} = 1 - \frac{T_L}{T_H} = 1 - \frac{350 \text{ K}}{1200 \text{ K}} = 70.83\%$$

$$Q_{\text{in}} = W_{\text{net,out}} / \eta_{\text{th}} = (0.5 \text{ kJ}) / (0.7083) = \mathbf{0.706 \text{ kJ}}$$

(c) The mass of helium is determined from

$$s_4 - s_3 = c_p \ln \frac{T_4}{T_3} - R \ln \frac{P_4}{P_3} = -(2.0769 \text{ kJ/kg}\cdot\text{K}) \ln \frac{300 \text{ kPa}}{150 \text{ kPa}}$$

$$= -1.4396 \text{ kJ/kg}\cdot\text{K} = s_1 - s_2$$

$$w_{\text{net,out}} = (s_2 - s_1)(T_H - T_L) = (1.4396 \text{ kJ/kg}\cdot\text{K})(1200 - 350) \text{ K} = 1223.7 \text{ kJ/kg}$$

$$m = \frac{W_{\text{net,out}}}{w_{\text{net,out}}} = \frac{0.5 \text{ kJ}}{1223.7 \text{ kJ/kg}} = \mathbf{0.000409 \text{ kg}}$$

9-20 A Carnot cycle with the specified temperature limits is considered. The net work output per cycle is to be determined.

Assumptions Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2).

Analysis The minimum pressure in the cycle is P_3 and the maximum pressure is P_1 . Then,

$$\frac{T_2}{T_3} = \left(\frac{P_2}{P_3} \right)^{(k-1)/k}$$

or

$$P_2 = P_3 \left(\frac{T_2}{T_3} \right)^{k/(k-1)} = (20 \text{ kPa}) \left(\frac{1100 \text{ K}}{300 \text{ K}} \right)^{1.4/0.4} = 1888 \text{ kPa}$$

The heat input is determined from

$$s_2 - s_1 = c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} = -(0.287 \text{ kJ/kg}\cdot\text{K}) \ln \frac{1888 \text{ kPa}}{3000 \text{ kPa}} = 0.1329 \text{ kJ/kg}\cdot\text{K}$$

$$Q_{\text{in}} = mT_H(s_2 - s_1) = (0.6 \text{ kg})(1100 \text{ K})(0.1329 \text{ kJ/kg}\cdot\text{K}) = 87.73 \text{ kJ}$$

Then,

$$\eta_{\text{th}} = 1 - \frac{T_L}{T_H} = 1 - \frac{300 \text{ K}}{1100 \text{ K}} = 0.7273 = 72.7\%$$

$$W_{\text{net,out}} = \eta_{\text{th}} Q_{\text{in}} = (0.7273)(87.73 \text{ kJ}) = \mathbf{63.8 \text{ kJ}}$$

9-21 A Carnot cycle executed in a closed system with air as the working fluid is considered. The minimum pressure in the cycle, the heat rejection from the cycle, the thermal efficiency of the cycle, and the second-law efficiency of an actual cycle operating between the same temperature limits are to be determined.

Assumptions Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperatures are $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2).

Analysis (a) The minimum temperature is determined from

$$w_{\text{net}} = (s_2 - s_1)(T_H - T_L) \longrightarrow 100 \text{ kJ/kg} = (0.25 \text{ kJ/kg}\cdot\text{K})(950 - T_L)\text{K} \longrightarrow T_L = 550 \text{ K}$$

The pressure at state 4 is determined from

$$\frac{T_1}{T_4} = \left(\frac{P_1}{P_4}\right)^{(k-1)/k}$$

or

$$P_1 = P_4 \left(\frac{T_1}{T_4}\right)^{k/(k-1)}$$

$$1300 \text{ kPa} = P_4 \left(\frac{950 \text{ K}}{550 \text{ K}}\right)^{1.4/0.4} \longrightarrow P_4 = 241.9 \text{ kPa}$$

The minimum pressure in the cycle is determined from

$$\begin{aligned} \Delta s_{12} = -\Delta s_{34} &= c_p \ln \frac{T_4}{T_3} - R \ln \frac{P_4}{P_3} \\ -0.25 \text{ kJ/kg}\cdot\text{K} &= -(0.287 \text{ kJ/kg}\cdot\text{K}) \ln \frac{241.9 \text{ kPa}}{P_3} \longrightarrow P_3 = \mathbf{101.2 \text{ kPa}} \end{aligned}$$

(b) The heat rejection from the cycle is

$$q_{\text{out}} = T_L \Delta s_{12} = (550 \text{ K})(0.25 \text{ kJ/kg}\cdot\text{K}) = \mathbf{137.5 \text{ kJ/kg}}$$

(c) The thermal efficiency is determined from

$$\eta_{\text{th}} = 1 - \frac{T_L}{T_H} = 1 - \frac{550 \text{ K}}{950 \text{ K}} = 0.421 = \mathbf{42.1\%}$$

(d) The power output for the Carnot cycle is

$$\dot{W}_{\text{Carnot}} = \dot{m}w_{\text{net}} = (95 \text{ kg/s})(100 \text{ kJ/kg}) = 9500 \text{ kW}$$

Then, the second-law efficiency of the actual cycle becomes

$$\eta_{\text{II}} = \frac{\dot{W}_{\text{actual}}}{\dot{W}_{\text{Carnot}}} = \frac{5200 \text{ kW}}{9500 \text{ kW}} = 0.547 = \mathbf{54.7\%}$$

9-22 An air-standard cycle executed in a piston-cylinder system is composed of three specified processes. The cycle is to be sketched on the P - v and T - s diagrams; the heat and work interactions and the thermal efficiency of the cycle are to be determined; and an expression for thermal efficiency as functions of compression ratio and specific heat ratio is to be obtained.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Properties The properties of air are given as $R = 0.3 \text{ kJ/kg}\cdot\text{K}$ and $c_v = 0.7 \text{ kJ/kg}\cdot\text{K}$.

Analysis (a) The P - v and T - s diagrams of the cycle are shown in the figures.

(b) Noting that

$$c_p = c_v + R = 0.7 + 0.3 = 1.0 \text{ kJ/kg}\cdot\text{K}$$

$$k = \frac{c_p}{c_v} = \frac{1.0}{0.7} = 1.429$$

Process 1-2: Isentropic compression

$$T_2 = T_1 \left(\frac{v_1}{v_2} \right)^{k-1} = T_1 r^{k-1} = (293 \text{ K})(5)^{0.429} = 584.4 \text{ K}$$

$$w_{1-2,\text{in}} = c_v(T_2 - T_1) = (0.7 \text{ kJ/kg}\cdot\text{K})(584.4 - 293) \text{ K} = \mathbf{204.0 \text{ kJ/kg}}$$

$$q_{1-2} = \mathbf{0}$$

From ideal gas relation,

$$\frac{T_3}{T_2} = \frac{v_3}{v_2} = \frac{v_1}{v_2} = r \longrightarrow T_3 = (584.4)(5) = 2922$$

Process 2-3: Constant pressure heat addition

$$\begin{aligned} w_{2-3,\text{out}} &= \int_2^3 P d v = P_2(v_3 - v_2) = R(T_3 - T_2) \\ &= (0.3 \text{ kJ/kg}\cdot\text{K})(2922 - 584.4) \text{ K} = \mathbf{701.3 \text{ kJ/kg}} \end{aligned}$$

$$\begin{aligned} q_{2-3,\text{in}} &= w_{2-3,\text{out}} + \Delta u_{2-3} = \Delta h_{2-3} \\ &= c_p(T_3 - T_2) = (1 \text{ kJ/kg}\cdot\text{K})(2922 - 584.4) \text{ K} = \mathbf{2338 \text{ kJ/kg}} \end{aligned}$$

Process 3-1: Constant volume heat rejection

$$q_{3-1,\text{out}} = \Delta u_{1-3} = c_v(T_3 - T_1) = (0.7 \text{ kJ/kg}\cdot\text{K})(2922 - 293) \text{ K} = \mathbf{1840.3 \text{ kJ/kg}}$$

$$w_{3-1} = \mathbf{0}$$

(c) Net work is

$$w_{\text{net}} = w_{2-3,\text{out}} - w_{1-2,\text{in}} = 701.3 - 204.0 = 497.3 \text{ kJ/kg}\cdot\text{K}$$

The thermal efficiency is then

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{497.3 \text{ kJ}}{2338 \text{ kJ}} = 0.213 = \mathbf{21.3\%}$$

(d) The expression for the cycle thermal efficiency is obtained as follows:

$$\begin{aligned}
\eta_{\text{th}} &= \frac{W_{\text{net}}}{q_{\text{in}}} = \frac{W_{2-3,\text{out}} - W_{1-2,\text{in}}}{q_{\text{in}}} \\
&= \frac{R(T_3 - T_2) - c_v(T_2 - T_1)}{c_p(T_3 - T_2)} \\
&= \frac{R}{c_p} - \frac{c_v(T_1 r^{k-1} - T_1)}{c_p(rT_1 r^{k-1} - T_1 r^{k-1})} \\
&= \frac{R}{c_p} - \frac{c_v T_1 r^{k-1} \left(1 - \frac{T_1}{T_1 r^{k-1}}\right)}{c_p T_1 r^{k-1} (r - 1)} \\
&= \frac{R}{c_p} - \frac{1}{k(r-1)} \left(1 - \frac{T_1}{T_1 r^{k-1}}\right) \\
&= \frac{R}{c_p} - \frac{1}{k(r-1)} \left(1 - \frac{1}{r^{k-1}}\right) \\
&= \left(1 - \frac{1}{k}\right) - \frac{1}{k(r-1)} \left(1 - \frac{1}{r^{k-1}}\right)
\end{aligned}$$

since

$$\frac{R}{c_p} = \frac{c_p - c_v}{c_p} = 1 - \frac{c_v}{c_p} = 1 - \frac{1}{k}$$

Otto Cycle

9-23C The four processes that make up the Otto cycle are (1) isentropic compression, (2) $v = \text{constant}$ heat addition, (3) isentropic expansion, and (4) $v = \text{constant}$ heat rejection.

9-24C They are analyzed as closed system processes because no mass crosses the system boundaries during any of the processes.

9-25C The ideal Otto cycle involves external irreversibilities, and thus it has a lower thermal efficiency.

9-26C It increases with both of them.

9-27C For actual four-stroke engines, the rpm is twice the number of thermodynamic cycles; for two-stroke engines, it is equal to the number of thermodynamic cycles.

9-28C Because high compression ratios cause engine knock.

9-29C The thermal efficiency will be the highest for argon because it has the highest specific heat ratio, $k = 1.667$.

9-30C The fuel is injected into the cylinder in both engines, but it is ignited with a spark plug in gasoline engines.

9-31 An ideal Otto cycle is considered. The thermal efficiency and the rate of heat input are to be determined.

Assumptions 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2a).

Analysis The definition of cycle thermal efficiency reduces to

$$\eta_{\text{th}} = 1 - \frac{1}{r^{k-1}} = 1 - \frac{1}{10.5^{1.4-1}} = 0.6096 = \mathbf{61.0\%}$$

The rate of heat addition is then

$$\dot{Q}_{\text{in}} = \frac{\dot{W}_{\text{net}}}{\eta_{\text{th}}} = \frac{90 \text{ kW}}{0.6096} = \mathbf{148 \text{ kW}}$$

9-32 An ideal Otto cycle is considered. The thermal efficiency and the rate of heat input are to be determined.

Assumptions 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2a).

Analysis The definition of cycle thermal efficiency reduces to

$$\eta_{\text{th}} = 1 - \frac{1}{r^{k-1}} = 1 - \frac{1}{8.5^{1.4-1}} = 0.5752 = \mathbf{57.5\%}$$

The rate of heat addition is then

$$\dot{Q}_{\text{in}} = \frac{\dot{W}_{\text{net}}}{\eta_{\text{th}}} = \frac{90 \text{ kW}}{0.5752} = \mathbf{157 \text{ kW}}$$

9-33 An ideal Otto cycle with air as the working fluid has a compression ratio of 8. The pressure and temperature at the end of the heat addition process, the net work output, the thermal efficiency, and the mean effective pressure for the cycle are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with variable specific heats.

Properties The gas constant of air is $R = 0.287 \text{ kJ/kg}\cdot\text{K}$. The properties of air are given in Table A-17.

Analysis (a) Process 1-2: isentropic compression.

$$T_1 = 300\text{K} \longrightarrow \begin{array}{l} u_1 = 214.07\text{kJ/kg} \\ \nu_{r_1} = 621.2 \end{array}$$

$$\nu_{r_2} = \frac{\nu_2}{\nu_1} \nu_{r_1} = \frac{1}{r} \nu_{r_1} = \frac{1}{8}(621.2) = 77.65 \longrightarrow \begin{array}{l} T_2 = 673.1\text{K} \\ u_2 = 491.2\text{kJ/kg} \end{array}$$

$$\frac{P_2 \nu_2}{T_2} = \frac{P_1 \nu_1}{T_1} \longrightarrow P_2 = \frac{\nu_1}{\nu_2} \frac{T_2}{T_1} P_1 = (8) \left(\frac{673.1\text{K}}{300\text{K}} \right) (95\text{ kPa}) = 1705\text{ kPa}$$

Process 2-3: $\nu = \text{constant}$ heat addition.

$$q_{23,\text{in}} = u_3 - u_2 \longrightarrow u_3 = u_2 + q_{23,\text{in}} = 491.2 + 750 = 1241.2\text{ kJ/kg} \longrightarrow \begin{array}{l} T_3 = 1539\text{K} \\ \nu_{r_3} = 6.588 \end{array}$$

$$\frac{P_3 \nu_3}{T_3} = \frac{P_2 \nu_2}{T_2} \longrightarrow P_3 = \frac{T_3}{T_2} P_2 = \left(\frac{1539\text{K}}{673.1\text{K}} \right) (1705\text{ kPa}) = 3898\text{ kPa}$$

(b) Process 3-4: isentropic expansion.

$$\nu_{r_4} = \frac{\nu_4}{\nu_3} \nu_{r_3} = r \nu_{r_3} = (8)(6.588) = 52.70 \longrightarrow \begin{array}{l} T_4 = 774.5\text{K} \\ u_4 = 571.69\text{kJ/kg} \end{array}$$

Process 4-1: $\nu = \text{constant}$ heat rejection.

$$q_{\text{out}} = u_4 - u_1 = 571.69 - 214.07 = 357.62\text{ kJ/kg}$$

$$w_{\text{net,out}} = q_{\text{in}} - q_{\text{out}} = 750 - 357.62 = 392.4\text{ kJ/kg}$$

$$(c) \quad \eta_{\text{th}} = \frac{w_{\text{net,out}}}{q_{\text{in}}} = \frac{392.4\text{ kJ/kg}}{750\text{ kJ/kg}} = 52.3\%$$

$$(d) \quad \nu_1 = \frac{RT_1}{P_1} = \frac{(0.287\text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(300\text{K})}{95\text{ kPa}} = 0.906\text{ m}^3/\text{kg} = \nu_{\text{max}}$$

$$\nu_{\text{min}} = \nu_2 = \frac{\nu_{\text{max}}}{r}$$

$$\text{MEP} = \frac{w_{\text{net,out}}}{\nu_1 - \nu_2} = \frac{w_{\text{net,out}}}{\nu_1(1 - 1/r)} = \frac{392.4\text{ kJ/kg}}{(0.906\text{ m}^3/\text{kg})(1 - 1/8)} \left(\frac{\text{kPa}\cdot\text{m}^3}{\text{kJ}} \right) = 495.0\text{ kPa}$$

9-34 Problem 9-33 is reconsidered. The effect of the compression ratio on the net work output and thermal efficiency is to be investigated. Also, T - s and P - v diagrams for the cycle are to be plotted.

Analysis Using EES, the problem is solved as follows:

9-35 An ideal Otto cycle with air as the working fluid has a compression ratio of 8. The pressure and temperature at the end of the heat addition process, the net work output, the thermal efficiency, and the mean effective pressure for the cycle are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2).

Analysis (a) Process 1-2: isentropic compression.

$$T_2 = T_1 \left(\frac{\nu_1}{\nu_2} \right)^{k-1} = (300 \text{ K})(8)^{0.4} = 689 \text{ K}$$

$$\frac{P_2 \nu_2}{T_2} = \frac{P_1 \nu_1}{T_1} \longrightarrow P_2 = \frac{\nu_1}{\nu_2} \frac{T_2}{T_1} P_1 = (8) \left(\frac{689 \text{ K}}{300 \text{ K}} \right) (95 \text{ kPa}) = 1745 \text{ kPa}$$

Process 2-3: $\nu = \text{constant}$ heat addition.

$$q_{23,\text{in}} = u_3 - u_2 = c_v (T_3 - T_2)$$

$$750 \text{ kJ/kg} = (0.718 \text{ kJ/kg}\cdot\text{K})(T_3 - 689 \text{ K})$$

$$T_3 = \mathbf{1734 \text{ K}}$$

$$\frac{P_3 \nu_3}{T_3} = \frac{P_2 \nu_2}{T_2} \longrightarrow P_3 = \frac{T_3}{T_2} P_2 = \left(\frac{1734 \text{ K}}{689 \text{ K}} \right) (1745 \text{ kPa}) = \mathbf{4392 \text{ kPa}}$$

(b) Process 3-4: isentropic expansion.

$$T_4 = T_3 \left(\frac{\nu_3}{\nu_4} \right)^{k-1} = (1734 \text{ K}) \left(\frac{1}{8} \right)^{0.4} = 755 \text{ K}$$

Process 4-1: $\nu = \text{constant}$ heat rejection.

$$q_{\text{out}} = u_4 - u_1 = c_v (T_4 - T_1) = (0.718 \text{ kJ/kg}\cdot\text{K})(755 - 300) \text{ K} = 327 \text{ kJ/kg}$$

$$w_{\text{net,out}} = q_{\text{in}} - q_{\text{out}} = 750 - 327 = \mathbf{423 \text{ kJ/kg}}$$

$$(c) \quad \eta_{\text{th}} = \frac{w_{\text{net,out}}}{q_{\text{in}}} = \frac{423 \text{ kJ/kg}}{750 \text{ kJ/kg}} = \mathbf{56.4\%}$$

$$(d) \quad \nu_1 = \frac{RT_1}{P_1} = \frac{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(300 \text{ K})}{95 \text{ kPa}} = 0.906 \text{ m}^3/\text{kg} = \nu_{\text{max}}$$

$$\nu_{\text{min}} = \nu_2 = \frac{\nu_{\text{max}}}{r}$$

$$\text{MEP} = \frac{w_{\text{net,out}}}{\nu_1 - \nu_2} = \frac{w_{\text{net,out}}}{\nu_1 (1 - 1/r)} = \frac{423 \text{ kJ/kg}}{(0.906 \text{ m}^3/\text{kg})(1 - 1/8)} \left(\frac{\text{kPa}\cdot\text{m}^3}{\text{kJ}} \right) = \mathbf{534 \text{ kPa}}$$

9-36E A six-cylinder, four-stroke, spark-ignition engine operating on the ideal Otto cycle is considered. The power produced by the engine is to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $R = 0.3704 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R}$ (Table A-1E), $c_p = 0.240 \text{ Btu}/\text{lbm} \cdot \text{R}$, $c_v = 0.171 \text{ Btu}/\text{lbm} \cdot \text{R}$, and $k = 1.4$ (Table A-2Ea).

Analysis From the data specified in the problem statement,

$$r = \frac{v_1}{v_2} = \frac{v_1}{0.098v_1} = 10.20$$

Since the compression and expansion processes are isentropic,

$$T_2 = T_1 \left(\frac{v_1}{v_2} \right)^{k-1} = T_1 r^{k-1} = (565 \text{ R})(10.20)^{1.4-1} = 1430.7 \text{ R}$$

$$T_4 = T_3 \left(\frac{v_3}{v_4} \right)^{k-1} = T_3 \left(\frac{1}{r} \right)^{k-1} = (2860 \text{ R}) \left(\frac{1}{10.20} \right)^{1.4-1} = 1129.4 \text{ R}$$

Application of the first law to the compression and expansion processes gives

$$\begin{aligned} w_{\text{net}} &= c_v(T_3 - T_4) - c_v(T_2 - T_1) \\ &= (0.171 \text{ Btu}/\text{lbm} \cdot \text{R})(2860 - 1129.4) \text{ R} - (0.171 \text{ Btu}/\text{lbm} \cdot \text{R})(1430.7 - 565) \text{ R} \\ &= 147.9 \text{ Btu}/\text{lbm} \end{aligned}$$

When each cylinder is charged with the air-fuel mixture,

$$v_1 = \frac{RT_1}{P_1} = \frac{(0.3704 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(565 \text{ R})}{14 \text{ psia}} = 14.95 \text{ ft}^3/\text{lbm}$$

The total air mass taken by all 6 cylinders when they are charged is

$$m = N_{\text{cyl}} \frac{\Delta V}{v_1} = N_{\text{cyl}} \frac{\pi B^2 S / 4}{v_1} = (6) \frac{\pi (3.5/12 \text{ ft})^2 (3.9/12 \text{ ft}) / 4}{14.95 \text{ ft}^3/\text{lbm}} = 0.008716 \text{ lbm}$$

The net work produced per cycle is

$$W_{\text{net}} = mw_{\text{net}} = (0.008716 \text{ lbm})(147.9 \text{ Btu}/\text{lbm}) = 1.289 \text{ Btu}/\text{cycle}$$

The power produced is determined from

$$\dot{W}_{\text{net}} = \frac{W_{\text{net}} \dot{n}}{N_{\text{rev}}} = \frac{(1.289 \text{ Btu}/\text{cycle})(2500/60 \text{ rev/s})}{2 \text{ rev}/\text{cycle}} \left(\frac{1 \text{ hp}}{0.7068 \text{ Btu/s}} \right) = \mathbf{38.0 \text{ hp}}$$

since there are two revolutions per cycle in a four-stroke engine.

9-37E An Otto cycle with non-isentropic compression and expansion processes is considered. The thermal efficiency, the heat addition, and the mean effective pressure are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $R = 0.3704 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R}$ (Table A-1E), $c_p = 0.240 \text{ Btu}/\text{lbm} \cdot \text{R}$, $c_v = 0.171 \text{ Btu}/\text{lbm} \cdot \text{R}$, and $k = 1.4$ (Table A-2Ea).

Analysis We begin by determining the temperatures of the cycle states using the process equations and component efficiencies. The ideal temperature at the end of the compression is then

$$T_{2s} = T_1 \left(\frac{v_1}{v_2} \right)^{k-1} = T_1 r^{k-1} = (520 \text{ R})(8)^{1.4-1} = 1195 \text{ R}$$

With the isentropic compression efficiency, the actual temperature at the end of the compression is

$$\eta = \frac{T_{2s} - T_1}{T_2 - T_1} \longrightarrow T_2 = T_1 + \frac{T_{2s} - T_1}{\eta} = (520 \text{ R}) + \frac{(1195 - 520) \text{ R}}{0.85} = 1314 \text{ R}$$

Similarly for the expansion,

$$T_{4s} = T_3 \left(\frac{v_3}{v_4} \right)^{k-1} = T_3 \left(\frac{1}{r} \right)^{k-1} = (2300 + 460 \text{ R}) \left(\frac{1}{8} \right)^{1.4-1} = 1201 \text{ R}$$

$$\eta = \frac{T_3 - T_4}{T_3 - T_{4s}} \longrightarrow T_4 = T_3 - \eta(T_3 - T_{4s}) = (2760 \text{ R}) - (0.95)(2760 - 1201) \text{ R} = 1279 \text{ R}$$

The specific heat addition is that of process 2-3,

$$q_{\text{in}} = c_v(T_3 - T_2) = (0.171 \text{ Btu}/\text{lbm} \cdot \text{R})(2760 - 1314) \text{ R} = \mathbf{247.3 \text{ Btu}/\text{lbm}}$$

The net work production is the difference between the work produced by the expansion and that used by the compression,

$$\begin{aligned} w_{\text{net}} &= c_v(T_3 - T_4) - c_v(T_2 - T_1) \\ &= (0.171 \text{ Btu}/\text{lbm} \cdot \text{R})(2760 - 1279) \text{ R} - (0.171 \text{ Btu}/\text{lbm} \cdot \text{R})(1314 - 520) \text{ R} \\ &= 117.5 \text{ Btu}/\text{lbm} \end{aligned}$$

The thermal efficiency of this cycle is then

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{117.5 \text{ Btu}/\text{lbm}}{247.3 \text{ Btu}/\text{lbm}} = \mathbf{0.475}$$

At the beginning of compression, the maximum specific volume of this cycle is

$$v_1 = \frac{RT_1}{P_1} = \frac{(0.3704 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(520 \text{ R})}{13 \text{ psia}} = 14.82 \text{ ft}^3/\text{lbm}$$

while the minimum specific volume of the cycle occurs at the end of the compression

$$v_2 = \frac{v_1}{r} = \frac{14.82 \text{ ft}^3/\text{lbm}}{8} = 1.852 \text{ ft}^3/\text{lbm}$$

The engine's mean effective pressure is then

$$\text{MEP} = \frac{w_{\text{net}}}{v_1 - v_2} = \frac{117.5 \text{ Btu}/\text{lbm}}{(14.82 - 1.852) \text{ ft}^3/\text{lbm}} \left(\frac{5.404 \text{ psia} \cdot \text{ft}^3}{1 \text{ Btu}} \right) = \mathbf{49.0 \text{ psia}}$$

9-38E An ideal Otto cycle with air as the working fluid has a compression ratio of 8. The amount of heat transferred to the air during the heat addition process, the thermal efficiency, and the thermal efficiency of a Carnot cycle operating between the same temperature limits are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with variable specific heats.

Properties The properties of air are given in Table A-17E.

Analysis (a) Process 1-2: isentropic compression.

$$T_1 = 540\text{R} \longrightarrow \begin{matrix} u_1 = 92.04\text{Btu/lbm} \\ \nu_{r_1} = 144.32 \end{matrix}$$

$$\nu_{r_2} = \frac{\nu_2}{\nu_1} \nu_{r_2} = \frac{1}{r} \nu_{r_2} = \frac{1}{8}(144.32) = 18.04 \longrightarrow u_2 = 211.28\text{ Btu/lbm}$$

Process 2-3: $\nu = \text{constant}$ heat addition.

$$T_3 = 2400\text{R} \longrightarrow \begin{matrix} u_3 = 452.70\text{ Btu/lbm} \\ \nu_{r_3} = 2.419 \end{matrix}$$

$$q_{in} = u_3 - u_2 = 452.70 - 211.28 = \mathbf{241.42\text{ Btu/lbm}}$$

(b) Process 3-4: isentropic expansion.

$$\nu_{r_4} = \frac{\nu_4}{\nu_3} \nu_{r_3} = r \nu_{r_3} = (8)(2.419) = 19.35 \longrightarrow u_4 = 205.54\text{ Btu/lbm}$$

Process 4-1: $\nu = \text{constant}$ heat rejection.

$$q_{out} = u_4 - u_1 = 205.54 - 92.04 = 113.50\text{ Btu/lbm}$$

$$\eta_{th} = 1 - \frac{q_{out}}{q_{in}} = 1 - \frac{113.50\text{ Btu/lbm}}{241.42\text{ Btu/lbm}} = \mathbf{53.0\%}$$

(c) The thermal efficiency of a Carnot cycle operating between the same temperature limits is

$$\eta_{th,C} = 1 - \frac{T_L}{T_H} = 1 - \frac{540\text{ R}}{2400\text{ R}} = \mathbf{77.5\%}$$

9-39E An ideal Otto cycle with argon as the working fluid has a compression ratio of 8. The amount of heat transferred to the argon during the heat addition process, the thermal efficiency, and the thermal efficiency of a Carnot cycle operating between the same temperature limits are to be determined.

Assumptions 1 The air-standard assumptions are applicable with argon as the working fluid. **2** Kinetic and potential energy changes are negligible. **3** Argon is an ideal gas with constant specific heats.

Properties The properties of argon are $c_p = 0.1253$ Btu/lbm.R, $c_v = 0.0756$ Btu/lbm.R, and $k = 1.667$ (Table A-2E).

Analysis (a) Process 1-2: isentropic compression.

$$T_2 = T_1 \left(\frac{v_1}{v_2} \right)^{k-1} = (540 \text{ R})(8)^{0.667} = 2161 \text{ R}$$

Process 2-3: $v = \text{constant}$ heat addition.

$$\begin{aligned} q_{\text{in}} &= u_3 - u_2 = c_v(T_3 - T_2) \\ &= (0.0756 \text{ Btu/lbm.R})(2400 - 2161) \text{ R} \\ &= \mathbf{18.07 \text{ Btu/lbm}} \end{aligned}$$

(b) Process 3-4: isentropic expansion.

$$T_4 = T_3 \left(\frac{v_3}{v_4} \right)^{k-1} = (2400 \text{ R}) \left(\frac{1}{8} \right)^{0.667} = 600 \text{ R}$$

Process 4-1: $v = \text{constant}$ heat rejection.

$$q_{\text{out}} = u_4 - u_1 = c_v(T_4 - T_1) = (0.0756 \text{ Btu/lbm.R})(600 - 540) \text{ R} = 4.536 \text{ Btu/lbm}$$

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{4.536 \text{ Btu/lbm}}{18.07 \text{ Btu/lbm}} = \mathbf{74.9\%}$$

(c) The thermal efficiency of a Carnot cycle operating between the same temperature limits is

$$\eta_{\text{th,C}} = 1 - \frac{T_L}{T_H} = 1 - \frac{540 \text{ R}}{2400 \text{ R}} = \mathbf{77.5\%}$$

9-40 The expressions for the maximum gas temperature and pressure of an ideal Otto cycle are to be determined when the compression ratio is doubled.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Analysis The temperature at the end of the compression varies with the compression ratio as

$$T_2 = T_1 \left(\frac{v_1}{v_2} \right)^{k-1} = T_1 r^{k-1}$$

since T_1 is fixed. The temperature rise during the combustion remains constant since the amount of heat addition is fixed. Then, the maximum cycle temperature is given by

$$T_3 = q_{in} / c_v + T_2 = q_{in} / c_v + T_1 r^{k-1}$$

The smallest gas specific volume during the cycle is

$$v_3 = \frac{v_1}{r}$$

When this is combined with the maximum temperature, the maximum pressure is given by

$$P_3 = \frac{RT_3}{v_3} = \frac{Rr}{v_1} (q_{in} / c_v + T_1 r^{k-1})$$

9-41 It is to be determined if the polytropic exponent to be used in an Otto cycle model will be greater than or less than the isentropic exponent.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Analysis During a polytropic process,

$$Pv^n = \text{constant}$$

$$TP^{(n-1)/n} = \text{constant}$$

and for an isentropic process,

$$Pv^k = \text{constant}$$

$$TP^{(k-1)/k} = \text{constant}$$

If heat is lost during the expansion of the gas,

$$T_4 > T_{4s}$$

where T_{4s} is the temperature that would occur if the expansion were reversible and adiabatic ($n=k$). This can only occur when

$$n \leq k$$

Diesel Cycle

9-42C A diesel engine differs from the gasoline engine in the way combustion is initiated. In diesel engines combustion is initiated by compressing the air above the self-ignition temperature of the fuel whereas it is initiated by a spark plug in a gasoline engine.

9-43C The Diesel cycle differs from the Otto cycle in the heat addition process only; it takes place at constant volume in the Otto cycle, but at constant pressure in the Diesel cycle.

9-44C The gasoline engine.

9-45C Diesel engines operate at high compression ratios because the diesel engines do not have the engine knock problem.

9-46 An air-standard Diesel cycle with a compression ratio of 16 and a cutoff ratio of 2 is considered. The temperature after the heat addition process, the thermal efficiency, and the mean effective pressure are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with variable specific heats.

Properties The gas constant of air is $R = 0.287 \text{ kJ/kg}\cdot\text{K}$. The properties of air are given in Table A-17.

Analysis (a) Process 1-2: isentropic compression.

$$T_1 = 300\text{K} \longrightarrow \begin{array}{l} u_1 = 214.07\text{kJ/kg} \\ \nu_{r_1} = 621.2 \end{array}$$

$$\nu_{r_2} = \frac{\nu_2}{\nu_1} \nu_{r_1} = \frac{1}{r} \nu_{r_1} = \frac{1}{16} (621.2) = 38.825 \longrightarrow \begin{array}{l} T_2 = 862.4 \text{ K} \\ h_2 = 890.9 \text{ kJ/kg} \end{array}$$

Process 2-3: $P = \text{constant}$ heat addition.

$$\frac{P_3 \nu_3}{T_3} = \frac{P_2 \nu_2}{T_2} \longrightarrow T_3 = \frac{\nu_3}{\nu_2} T_2 = 2T_2 = (2)(862.4 \text{ K}) = \mathbf{1724.8 \text{ K}} \longrightarrow \begin{array}{l} h_3 = 1910.6 \text{ kJ/kg} \\ \nu_{r_3} = 4.546 \end{array}$$

$$(b) \quad q_{\text{in}} = h_3 - h_2 = 1910.6 - 890.9 = 1019.7 \text{ kJ/kg}$$

Process 3-4: isentropic expansion.

$$\nu_{r_4} = \frac{\nu_4}{\nu_3} \nu_{r_3} = \frac{\nu_4}{2\nu_2} \nu_{r_3} = \frac{r}{2} \nu_{r_3} = \frac{16}{2} (4.546) = 36.37 \longrightarrow u_4 = 659.7 \text{ kJ/kg}$$

Process 4-1: $\nu = \text{constant}$ heat rejection.

$$q_{\text{out}} = u_4 - u_1 = 659.7 - 214.07 = 445.63 \text{ kJ/kg}$$

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{445.63 \text{ kJ/kg}}{1019.7 \text{ kJ/kg}} = \mathbf{56.3\%}$$

$$(c) \quad w_{\text{net,out}} = q_{\text{in}} - q_{\text{out}} = 1019.7 - 445.63 = 574.07 \text{ kJ/kg}$$

$$\nu_1 = \frac{RT_1}{P_1} = \frac{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(300 \text{ K})}{95 \text{ kPa}} = 0.906 \text{ m}^3/\text{kg} = \nu_{\text{max}}$$

$$\nu_{\text{min}} = \nu_2 = \frac{\nu_{\text{max}}}{r}$$

$$\text{MEP} = \frac{w_{\text{net,out}}}{\nu_1 - \nu_2} = \frac{w_{\text{net,out}}}{\nu_1(1 - 1/r)} = \frac{574.07 \text{ kJ/kg}}{(0.906 \text{ m}^3/\text{kg})(1 - 1/16)} \left(\frac{\text{kPa}\cdot\text{m}^3}{\text{kJ}} \right) = \mathbf{675.9 \text{ kPa}}$$

9-47 An air-standard Diesel cycle with a compression ratio of 16 and a cutoff ratio of 2 is considered. The temperature after the heat addition process, the thermal efficiency, and the mean effective pressure are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2).

Analysis (a) Process 1-2: isentropic compression.

$$T_2 = T_1 \left(\frac{v_1}{v_2} \right)^{k-1} = (300\text{K})(16)^{0.4} = 909.4\text{K}$$

Process 2-3: $P = \text{constant}$ heat addition.

$$\frac{P_3 v_3}{T_3} = \frac{P_2 v_2}{T_2} \longrightarrow T_3 = \frac{v_3}{v_2} T_2 = 2T_2 = (2)(909.4\text{K}) = \mathbf{1818.8\text{K}}$$

$$(b) \quad q_{\text{in}} = h_3 - h_2 = c_p(T_3 - T_2) = (1.005 \text{ kJ/kg}\cdot\text{K})(1818.8 - 909.4)\text{K} = 913.9 \text{ kJ/kg}$$

Process 3-4: isentropic expansion.

$$T_4 = T_3 \left(\frac{v_3}{v_4} \right)^{k-1} = T_3 \left(\frac{2v_2}{v_4} \right)^{k-1} = (1818.8\text{K}) \left(\frac{2}{16} \right)^{0.4} = 791.7\text{K}$$

Process 4-1: $v = \text{constant}$ heat rejection.

$$q_{\text{out}} = u_4 - u_1 = c_v(T_4 - T_1) = (0.718 \text{ kJ/kg}\cdot\text{K})(791.7 - 300)\text{K} = 353 \text{ kJ/kg}$$

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{353 \text{ kJ/kg}}{913.9 \text{ kJ/kg}} = \mathbf{61.4\%}$$

$$(c) \quad w_{\text{net,out}} = q_{\text{in}} - q_{\text{out}} = 913.9 - 353 = 560.9 \text{ kJ/kg}$$

$$v_1 = \frac{RT_1}{P_1} = \frac{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(300 \text{ K})}{95 \text{ kPa}} = 0.906 \text{ m}^3/\text{kg} = v_{\text{max}}$$

$$v_{\text{min}} = v_2 = \frac{v_{\text{max}}}{r}$$

$$\text{MEP} = \frac{w_{\text{net,out}}}{v_1 - v_2} = \frac{w_{\text{net,out}}}{v_1(1 - 1/r)} = \frac{560.9 \text{ kJ/kg}}{(0.906 \text{ m}^3/\text{kg})(1 - 1/16)} \left(\frac{\text{kPa}\cdot\text{m}^3}{\text{kJ}} \right) = \mathbf{660.4 \text{ kPa}}$$

9-48 An ideal diesel cycle has a compression ratio of 17 and a cutoff ratio of 1.3. The maximum temperature of the air and the rate of heat addition are to be determined.

Assumptions 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2a).

Analysis We begin by using the process types to fix the temperatures of the states.

$$T_2 = T_1 \left(\frac{v_1}{v_2} \right)^{k-1} = T_1 r^{k-1} = (330 \text{ K})(17)^{1.4-1} = 1025 \text{ K}$$

$$T_3 = T_2 \left(\frac{v_3}{v_2} \right) = T_2 r_c = (1025 \text{ K})(1.3) = \mathbf{1332 \text{ K}}$$

Combining the first law as applied to the various processes with the process equations gives

$$\eta_{\text{th}} = 1 - \frac{1}{r^{k-1}} \frac{r_c^k - 1}{k(r_c - 1)} = 1 - \frac{1}{17^{1.4-1}} \frac{1.3^{1.4} - 1}{1.4(1.3 - 1)} = 0.6597$$

According to the definition of the thermal efficiency,

$$\dot{Q}_{\text{in}} = \frac{\dot{W}_{\text{net}}}{\eta_{\text{th}}} = \frac{140 \text{ kW}}{0.6597} = \mathbf{212 \text{ kW}}$$

9-49E An ideal diesel cycle has a cutoff ratio of 1.4. The power produced is to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $R = 0.3704 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R}$ (Table A-1E), $c_p = 0.240 \text{ Btu}/\text{lbm} \cdot \text{R}$, $c_v = 0.171 \text{ Btu}/\text{lbm} \cdot \text{R}$, and $k = 1.4$ (Table A-2Ea).

Analysis The specific volume of the air at the start of the compression is

$$\nu_1 = \frac{RT_1}{P_1} = \frac{(0.3704 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(510 \text{ R})}{14.4 \text{ psia}} = 13.12 \text{ ft}^3/\text{lbm}$$

The total air mass taken by all 8 cylinders when they are charged is

$$m = N_{\text{cyl}} \frac{\Delta V}{\nu_1} = N_{\text{cyl}} \frac{\pi B^2 S / 4}{\nu_1} = (8) \frac{\pi (4/12 \text{ ft})^2 (4/12 \text{ ft}) / 4}{13.12 \text{ ft}^3/\text{lbm}} = 0.01774 \text{ lbm}$$

The rate at which air is processed by the engine is determined from

$$\dot{m} = \frac{m\dot{n}}{N_{\text{rev}}} = \frac{(0.01774 \text{ lbm}/\text{cycle})(1800/60 \text{ rev/s})}{2 \text{ rev}/\text{cycle}} = 0.2661 \text{ lbm/s} = 958.0 \text{ lbm/h}$$

since there are two revolutions per cycle in a four-stroke engine. The compression ratio is

$$r = \frac{1}{0.045} = 22.22$$

At the end of the compression, the air temperature is

$$T_2 = T_1 r^{k-1} = (510 \text{ R})(22.22)^{1.4-1} = 1763 \text{ R}$$

Application of the first law and work integral to the constant pressure heat addition gives

$$q_{\text{in}} = c_p (T_3 - T_2) = (0.240 \text{ Btu}/\text{lbm} \cdot \text{R})(2760 - 1763) \text{ R} = 239.3 \text{ Btu}/\text{lbm}$$

while the thermal efficiency is

$$\eta_{\text{th}} = 1 - \frac{1}{r^{k-1}} \frac{r_c^k - 1}{k(r_c - 1)} = 1 - \frac{1}{22.22^{1.4-1}} \frac{1.4^{1.4} - 1}{1.4(1.4 - 1)} = 0.6892$$

The power produced by this engine is then

$$\begin{aligned} \dot{W}_{\text{net}} &= \dot{m} w_{\text{net}} = \dot{m} \eta_{\text{th}} q_{\text{in}} \\ &= (958.0 \text{ lbm/h})(0.6892)(239.3 \text{ Btu}/\text{lbm}) \left(\frac{1 \text{ hp}}{2544.5 \text{ Btu/h}} \right) \\ &= \mathbf{62.1 \text{ hp}} \end{aligned}$$

9-50 An ideal dual cycle has a compression ratio of 14 and cutoff ratio of 1.2. The thermal efficiency, amount of heat added, and the maximum gas pressure and temperature are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2a).

Analysis The specific volume of the air at the start of the compression is

$$\nu_1 = \frac{RT_1}{P_1} = \frac{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(293 \text{ K})}{80 \text{ kPa}} = 1.051 \text{ m}^3/\text{kg}$$

and the specific volume at the end of the compression is

$$\nu_2 = \frac{\nu_1}{r} = \frac{1.051 \text{ m}^3/\text{kg}}{14} = 0.07508 \text{ m}^3/\text{kg}$$

The pressure at the end of the compression is

$$P_2 = P_1 \left(\frac{\nu_1}{\nu_2} \right)^k = P_1 r^k = (80 \text{ kPa})(14)^{1.4} = 3219 \text{ kPa}$$

and the maximum pressure is

$$P_x = P_3 = r_p P_2 = (1.5)(3219 \text{ kPa}) = \mathbf{4829 \text{ kPa}}$$

The temperature at the end of the compression is

$$T_2 = T_1 \left(\frac{\nu_1}{\nu_2} \right)^{k-1} = T_1 r^{k-1} = (293 \text{ K})(14)^{1.4-1} = 842.0 \text{ K}$$

and
$$T_x = T_2 \left(\frac{P_3}{P_2} \right) = (842.0 \text{ K}) \left(\frac{4829 \text{ kPa}}{3219 \text{ kPa}} \right) = 1263 \text{ K}$$

From the definition of cutoff ratio

$$\nu_3 = r_c \nu_x = r_c \nu_2 = (1.2)(0.07508 \text{ m}^3/\text{kg}) = 0.09010 \text{ m}^3/\text{kg}$$

The remaining state temperatures are then

$$T_3 = T_x \left(\frac{\nu_3}{\nu_x} \right) = (1263 \text{ K}) \left(\frac{0.09010}{0.07508} \right) = \mathbf{1516 \text{ K}}$$

$$T_4 = T_3 \left(\frac{\nu_3}{\nu_4} \right)^{k-1} = (1516 \text{ K}) \left(\frac{0.09010}{1.051} \right)^{1.4-1} = 567.5 \text{ K}$$

Applying the first law and work expression to the heat addition processes gives

$$\begin{aligned} q_{\text{in}} &= c_v(T_x - T_2) + c_p(T_3 - T_x) \\ &= (0.718 \text{ kJ/kg}\cdot\text{K})(1263 - 842.0)\text{K} + (1.005 \text{ kJ/kg}\cdot\text{K})(1516 - 1263)\text{K} \\ &= \mathbf{556.5 \text{ kJ/kg}} \end{aligned}$$

The heat rejected is

$$q_{\text{out}} = c_v(T_4 - T_1) = (0.718 \text{ kJ/kg}\cdot\text{K})(567.5 - 293)\text{K} = 197.1 \text{ kJ/kg}$$

Then,
$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{197.1 \text{ kJ/kg}}{556.5 \text{ kJ/kg}} = \mathbf{0.646}$$

9-51 An ideal dual cycle has a compression ratio of 14 and cutoff ratio of 1.2. The thermal efficiency, amount of heat added, and the maximum gas pressure and temperature are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2).

Analysis The specific volume of the air at the start of the compression is

$$\nu_1 = \frac{RT_1}{P_1} = \frac{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(253 \text{ K})}{80 \text{ kPa}} = 0.9076 \text{ m}^3/\text{kg}$$

and the specific volume at the end of the compression is

$$\nu_2 = \frac{\nu_1}{r} = \frac{0.9076 \text{ m}^3/\text{kg}}{14} = 0.06483 \text{ m}^3/\text{kg}$$

The pressure at the end of the compression is

$$P_2 = P_1 \left(\frac{\nu_1}{\nu_2} \right)^k = P_1 r^k = (80 \text{ kPa})(14)^{1.4} = 3219 \text{ kPa}$$

and the maximum pressure is

$$P_x = P_3 = r_p P_2 = (1.5)(3219 \text{ kPa}) = \mathbf{4829 \text{ kPa}}$$

The temperature at the end of the compression is

$$T_2 = T_1 \left(\frac{\nu_1}{\nu_2} \right)^{k-1} = T_1 r^{k-1} = (253 \text{ K})(14)^{1.4-1} = 727.1 \text{ K}$$

and

$$T_x = T_2 \left(\frac{P_3}{P_2} \right) = (727.1 \text{ K}) \left(\frac{4829 \text{ kPa}}{3219 \text{ kPa}} \right) = 1091 \text{ K}$$

From the definition of cutoff ratio

$$\nu_3 = r_c \nu_x = r_c \nu_2 = (1.2)(0.06483 \text{ m}^3/\text{kg}) = 0.07780 \text{ m}^3/\text{kg}$$

The remaining state temperatures are then

$$T_3 = T_x \left(\frac{\nu_3}{\nu_x} \right) = (1091 \text{ K}) \left(\frac{0.07780}{0.06483} \right) = \mathbf{1309 \text{ K}}$$

$$T_4 = T_3 \left(\frac{\nu_3}{\nu_4} \right)^{k-1} = (1309 \text{ K}) \left(\frac{0.07780}{0.9076} \right)^{1.4-1} = 490.0 \text{ K}$$

Applying the first law and work expression to the heat addition processes gives

$$\begin{aligned} q_{\text{in}} &= c_v(T_x - T_2) + c_p(T_3 - T_x) \\ &= (0.718 \text{ kJ/kg}\cdot\text{K})(1091 - 727.1)\text{K} + (1.005 \text{ kJ/kg}\cdot\text{K})(1309 - 1091)\text{K} \\ &= \mathbf{480.4 \text{ kJ/kg}} \end{aligned}$$

The heat rejected is

$$q_{\text{out}} = c_v(T_4 - T_1) = (0.718 \text{ kJ/kg}\cdot\text{K})(490.0 - 253)\text{K} = 170.2 \text{ kJ/kg}$$

Then,

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{170.2 \text{ kJ/kg}}{480.4 \text{ kJ/kg}} = \mathbf{0.646}$$

9-52E An air-standard Diesel cycle with a compression ratio of 18.2 is considered. The cutoff ratio, the heat rejection per unit mass, and the thermal efficiency are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with variable specific heats.

Properties The properties of air are given in Table A-17E.

Analysis (a) Process 1-2: isentropic compression.

$$T_1 = 580 \text{ R} \longrightarrow \begin{array}{l} u_1 = 98.90 \text{ Btu/lbm} \\ v_{r_1} = 120.70 \end{array}$$

$$v_{r_2} = \frac{v_2}{v_1} v_{r_1} = \frac{1}{r} v_{r_1} = \frac{1}{18.2} (120.70) = 6.632 \longrightarrow \begin{array}{l} T_2 = 1725.8 \text{ R} \\ h_2 = 429.56 \text{ Btu/lbm} \end{array}$$

Process 2-3: $P = \text{constant}$ heat addition.

$$\frac{P_3 v_3}{T_3} = \frac{P_2 v_2}{T_2} \longrightarrow \frac{v_3}{v_2} = \frac{T_3}{T_2} = \frac{3200 \text{ R}}{1725.8 \text{ R}} = \mathbf{1.854}$$

$$(b) \quad T_3 = 3200 \text{ R} \longrightarrow \begin{array}{l} h_3 = 849.48 \text{ Btu/lbm} \\ v_{r_3} = 0.955 \end{array}$$

$$q_{\text{in}} = h_3 - h_2 = 849.48 - 429.56 = 419.9 \text{ Btu/lbm}$$

Process 3-4: isentropic expansion.

$$v_{r_4} = \frac{v_4}{v_3} v_{r_3} = \frac{v_4}{1.854 v_2} v_{r_3} = \frac{r}{1.854} v_{r_3} = \frac{18.2}{1.854} (0.955) = 9.375 \longrightarrow u_4 = 272.58 \text{ Btu/lbm}$$

Process 4-1: $v = \text{constant}$ heat rejection:

$$q_{\text{out}} = u_4 - u_1 = 272.58 - 98.90 = \mathbf{173.7 \text{ Btu/lbm}}$$

$$(c) \quad \eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{173.7 \text{ Btu/lbm}}{419.9 \text{ Btu/lbm}} = 0.586 = \mathbf{58.6\%}$$

9-53E An air-standard Diesel cycle with a compression ratio of 18.2 is considered. The cutoff ratio, the heat rejection per unit mass, and the thermal efficiency are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 0.240$ Btu/lbm.R, $c_v = 0.171$ Btu/lbm.R, and $k = 1.4$ (Table A-2E).

Analysis (a) Process 1-2: isentropic compression.

$$T_2 = T_1 \left(\frac{v_1}{v_2} \right)^{k-1} = (580 \text{ R})(18.2)^{0.4} = 1851 \text{ R}$$

Process 2-3: $P = \text{constant}$ heat addition.

$$\frac{P_3 v_3}{T_3} = \frac{P_2 v_2}{T_2} \longrightarrow \frac{v_3}{v_2} = \frac{T_3}{T_2} = \frac{3200 \text{ R}}{1851 \text{ R}} = \mathbf{1.729}$$

$$(b) \quad q_{\text{in}} = h_3 - h_2 = c_p(T_3 - T_2) = (0.240 \text{ Btu/lbm.R})(3200 - 1851) \text{ R} = 323.7 \text{ Btu/lbm}$$

Process 3-4: isentropic expansion.

$$T_4 = T_3 \left(\frac{v_3}{v_4} \right)^{k-1} = T_3 \left(\frac{1.729 v_2}{v_4} \right)^{k-1} = (3200 \text{ R}) \left(\frac{1.729}{18.2} \right)^{0.4} = 1248 \text{ R}$$

Process 4-1: $v = \text{constant}$ heat rejection.

$$\begin{aligned} q_{\text{out}} &= u_4 - u_1 = c_v(T_4 - T_1) \\ &= (0.171 \text{ Btu/lbm.R})(1248 - 580) \text{ R} \\ &= \mathbf{114.2 \text{ Btu/lbm}} \end{aligned}$$

$$(c) \quad \eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{114.2 \text{ Btu/lbm}}{323.7 \text{ Btu/lbm}} = 0.6472 = \mathbf{64.7\%}$$

9-54 An ideal diesel engine with air as the working fluid has a compression ratio of 20. The thermal efficiency and the mean effective pressure are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2).

Analysis (a) Process 1-2: isentropic compression.

$$T_2 = T_1 \left(\frac{v_1}{v_2} \right)^{k-1} = (293 \text{ K})(20)^{0.4} = 971.1 \text{ K}$$

Process 2-3: $P = \text{constant}$ heat addition.

$$\frac{P_3 v_3}{T_3} = \frac{P_2 v_2}{T_2} \longrightarrow \frac{v_3}{v_2} = \frac{T_3}{T_2} = \frac{2200 \text{ K}}{971.1 \text{ K}} = 2.265$$

Process 3-4: isentropic expansion.

$$T_4 = T_3 \left(\frac{v_3}{v_4} \right)^{k-1} = T_3 \left(\frac{2.265 v_2}{v_4} \right)^{k-1} = T_3 \left(\frac{2.265}{r} \right)^{k-1} = (2200 \text{ K}) \left(\frac{2.265}{20} \right)^{0.4} = 920.6 \text{ K}$$

$$q_{\text{in}} = h_3 - h_2 = c_p (T_3 - T_2) = (1.005 \text{ kJ/kg}\cdot\text{K})(2200 - 971.1) \text{ K} = 1235 \text{ kJ/kg}$$

$$q_{\text{out}} = u_4 - u_1 = c_v (T_4 - T_1) = (0.718 \text{ kJ/kg}\cdot\text{K})(920.6 - 293) \text{ K} = 450.6 \text{ kJ/kg}$$

$$w_{\text{net,out}} = q_{\text{in}} - q_{\text{out}} = 1235 - 450.6 = 784.4 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net,out}}}{q_{\text{in}}} = \frac{784.4 \text{ kJ/kg}}{1235 \text{ kJ/kg}} = \mathbf{63.5\%}$$

$$(b) \quad v_1 = \frac{RT_1}{P_1} = \frac{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(293 \text{ K})}{95 \text{ kPa}} = 0.885 \text{ m}^3/\text{kg} = v_{\text{max}}$$

$$v_{\text{min}} = v_2 = \frac{v_{\text{max}}}{r}$$

$$\text{MEP} = \frac{w_{\text{net,out}}}{v_1 - v_2} = \frac{w_{\text{net,out}}}{v_1 (1 - 1/r)} = \frac{784.4 \text{ kJ/kg}}{(0.885 \text{ m}^3/\text{kg})(1 - 1/20)} \left(\frac{\text{kPa}\cdot\text{m}^3}{\text{kJ}} \right) = \mathbf{933 \text{ kPa}}$$

9-55 A diesel engine with air as the working fluid has a compression ratio of 20. The thermal efficiency and the mean effective pressure are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Properties The gas constant of air is $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ (Table A-2).

Analysis (a) Process 1-2: isentropic compression.

$$T_1 = 293 \text{ K} \longrightarrow \begin{matrix} u_1 = 209.06 \text{ kJ/kg} \\ \nu_{r_1} = 659.2 \end{matrix} \quad (\text{Table A-17})$$

$$\nu_{r_2} = \frac{\nu_2}{\nu_1} \nu_{r_1} = \frac{1}{r} \nu_{r_1} = \frac{1}{20} (659.2) = 32.96 \longrightarrow \begin{matrix} T_2 = 912.7 \text{ K} \\ h_2 = 947.17 \text{ kJ/kg} \end{matrix} \quad (\text{Table A-17})$$

Process 2-3: $P = \text{constant}$ heat addition.

$$\frac{P_3 \nu_3}{T_3} = \frac{P_2 \nu_2}{T_2} \longrightarrow \frac{\nu_3}{\nu_2} = \frac{T_3}{T_2} = \frac{2200 \text{ K}}{912.7 \text{ K}} = 2.410$$

$$T_3 = 2200 \text{ K} \longrightarrow \begin{matrix} h_3 = 2503.2 \text{ kJ/kg}, \\ u_3 = 1872.4 \text{ kJ/kg} \end{matrix} \quad (\text{Table A-17})$$

$$q_{\text{in}} = h_3 - h_2 = 2503.2 - 947.17 = 1556.0 \text{ kJ/kg}$$

Process 3-4: polytropic expansion.

$$T_4 = T_3 \left(\frac{\nu_3}{\nu_4} \right)^{n-1} = T_3 \left(\frac{2.410 \nu_2}{\nu_4} \right)^{n-1} = T_3 \left(\frac{2.410}{r} \right)^{n-1} = (2200 \text{ K}) \left(\frac{2.410}{20} \right)^{0.35} = 1049 \text{ K}$$

$$w_{34,\text{out}} = \frac{R(T_4 - T_3)}{1 - n} = \frac{(0.287 \text{ kJ/kg}\cdot\text{K})(1049 - 2200) \text{ K}}{1 - 1.35} = 943.8 \text{ kJ/kg}$$

$$T_4 = 1049 \text{ K} \longrightarrow u_4 = 801.13 \text{ kJ/kg} \quad (\text{Table A-17})$$

An energy balance gives

$$E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$$

$$\begin{aligned} -q_{34,\text{out}} - w_{34,\text{out}} &= u_4 - u_3 \longrightarrow q_{34,\text{out}} = -w_{34,\text{out}} - (u_4 - u_3) \\ &= -943.8 \text{ kJ/kg} - (801.13 - 1872.4) \text{ kJ/kg} = 127.5 \text{ kJ/kg} \end{aligned}$$

Process 4-1: $\nu = \text{constant}$ heat rejection.

$$q_{41,\text{out}} = u_4 - u_1 = (801.13 - 209.06) \text{ kJ/kg} = 592.1 \text{ kJ/kg}$$

Total heat rejected is

$$q_{\text{out}} = q_{34,\text{out}} + q_{41,\text{out}} = 127.5 + 592.1 = 719.6 \text{ kJ/kg}$$

and

$$w_{\text{net,out}} = q_{\text{in}} - q_{\text{out}} = 1556 - 719.6 = 836.4 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net,out}}}{q_{\text{in}}} = \frac{836.4 \text{ kJ/kg}}{1556 \text{ kJ/kg}} = 0.5375 = \mathbf{53.8\%}$$

$$(b) \quad \nu_1 = \frac{RT_1}{P_1} = \frac{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(293 \text{ K})}{95 \text{ kPa}} = 0.8852 \text{ m}^3/\text{kg} = \nu_{\text{max}}$$

$$\nu_{\text{min}} = \nu_2 = \frac{\nu_{\text{max}}}{r}$$

$$\text{MEP} = \frac{w_{\text{net,out}}}{\nu_1 - \nu_2} = \frac{w_{\text{net,out}}}{\nu_1(1 - 1/r)} = \frac{836.4 \text{ kJ/kg}}{(0.8852 \text{ m}^3/\text{kg})(1 - 1/20)} \left(\frac{1 \text{ kPa}\cdot\text{m}^3}{\text{kJ}} \right) = \mathbf{995 \text{ kPa}}$$

9-56 Problem 9-55 is reconsidered. The effect of the compression ratio on the net work output, mean effective pressure, and thermal efficiency is to be investigated. Also, T - s and P - v diagrams for the cycle are to be plotted.

Analysis Using EES, the problem is solved as follows:

```

Procedure QTotal(q_12,q_23,q_34,q_41: q_in_total,q_out_total)
q_in_total = 0
q_out_total = 0
IF (q_12 > 0) THEN q_in_total = q_12 ELSE q_out_total = - q_12
If q_23 > 0 then q_in_total = q_in_total + q_23 else q_out_total = q_out_total - q_23
If q_34 > 0 then q_in_total = q_in_total + q_34 else q_out_total = q_out_total - q_34
If q_41 > 0 then q_in_total = q_in_total + q_41 else q_out_total = q_out_total - q_41
END

9-57 A four-cylinder ideal diesel engine with air as the working fluid has a compression ratio of 22 and a cutoff ratio of 1.8. The power the engine will deliver at 2300 rpm is to be determined.

Assumptions 1 The cold air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2).

Analysis Process 1-2: isentropic compression.

$$T_2 = T_1 \left(\frac{v_1}{v_2} \right)^{k-1} = (343 \text{ K})(22)^{0.4} = 1181 \text{ K}$$

Process 2-3: $P = \text{constant}$ heat addition.

$$\frac{P_3 v_3}{T_3} = \frac{P_2 v_2}{T_2} \longrightarrow T_3 = \frac{v_3}{v_2} T_2 = 1.8 T_2 = (1.8)(1181 \text{ K}) = 2126 \text{ K}$$

Process 3-4: isentropic expansion.

$$T_4 = T_3 \left(\frac{v_3}{v_4} \right)^{k-1} = T_3 \left(\frac{2.2 v_2}{v_4} \right)^{k-1} = T_3 \left(\frac{2.2}{r} \right)^{k-1} = (2216 \text{ K}) \left(\frac{1.8}{22} \right)^{0.4} = 781 \text{ K}$$

For the cycle:

$$m = \frac{P_1 v_1}{RT_1} = \frac{(97 \text{ kPa})(0.0024 \text{ m}^3)}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(343 \text{ K})} = 0.002365 \text{ kg}$$

$$\begin{aligned} Q_{\text{in}} &= m(h_3 - h_2) = mc_p(T_3 - T_2) \\ &= (0.002365 \text{ kg})(1.005 \text{ kJ/kg}\cdot\text{K})(2216 - 1181)\text{K} \\ &= 2.246 \text{ kJ} \end{aligned}$$

$$\begin{aligned} Q_{\text{out}} &= m(u_4 - u_1) = mc_v(T_4 - T_1) \\ &= (0.002365 \text{ kg})(0.718 \text{ kJ/kg}\cdot\text{K})(781 - 343)\text{K} \\ &= 0.7438 \text{ kJ} \end{aligned}$$

$$W_{\text{net,out}} = Q_{\text{in}} - Q_{\text{out}} = 2.246 - 0.7438 = 1.502 \text{ kJ/rev}$$

$$\dot{W}_{\text{net,out}} = \dot{n} W_{\text{net,out}} = (3500/60 \text{ rev/s})(1.502 \text{ kJ/rev}) = \mathbf{87.6 \text{ kW}}$$

Discussion Note that for 2-stroke engines, 1 thermodynamic cycle is equivalent to 1 mechanical cycle (and thus revolutions).

9-58 A four-cylinder ideal diesel engine with nitrogen as the working fluid has a compression ratio of 22 and a cutoff ratio of 1.8. The power the engine will deliver at 2300 rpm is to be determined.

Assumptions 1 The air-standard assumptions are applicable with nitrogen as the working fluid. **2** Kinetic and potential energy changes are negligible. **3** Nitrogen is an ideal gas with constant specific heats.

Properties The properties of nitrogen at room temperature are $c_p = 1.039 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.743 \text{ kJ/kg}\cdot\text{K}$, $R = 0.2968 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2).

Analysis Process 1-2: isentropic compression.

$$T_2 = T_1 \left(\frac{v_1}{v_2} \right)^{k-1} = (343 \text{ K})(22)^{0.4} = 1181 \text{ K}$$

Process 2-3: $P = \text{constant}$ heat addition.

$$\frac{P_3 v_3}{T_3} = \frac{P_2 v_2}{T_2} \longrightarrow T_3 = \frac{v_3}{v_2} T_2 = 1.8 T_2 = (1.8)(1181 \text{ K}) = 2126 \text{ K}$$

Process 3-4: isentropic expansion.

$$T_4 = T_3 \left(\frac{v_3}{v_4} \right)^{k-1} = T_3 \left(\frac{2.2 v_2}{v_4} \right)^{k-1} = T_3 \left(\frac{2.2}{r} \right)^{k-1} = (2126 \text{ K}) \left(\frac{1.8}{22} \right)^{0.4} = 781 \text{ K}$$

For the cycle:

$$m = \frac{P_1 v_1}{RT_1} = \frac{(97 \text{ kPa})(0.0024 \text{ m}^3)}{(0.2968 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(343 \text{ K})} = 0.002287 \text{ kg}$$

$$\begin{aligned} Q_{\text{in}} &= m(h_3 - h_2) = mc_p(T_3 - T_2) \\ &= (0.002287 \text{ kg})(1.039 \text{ kJ/kg}\cdot\text{K})(2126 - 1181) \text{ K} \\ &= 2.245 \text{ kJ} \end{aligned}$$

$$\begin{aligned} Q_{\text{out}} &= m(u_4 - u_1) = mc_v(T_4 - T_1) \\ &= (0.002287 \text{ kg})(0.743 \text{ kJ/kg}\cdot\text{K})(781 - 343) \text{ K} \\ &= 0.7443 \text{ kJ} \end{aligned}$$

$$W_{\text{net,out}} = Q_{\text{in}} - Q_{\text{out}} = 2.245 - 0.7443 = 1.501 \text{ kJ/rev}$$

$$\dot{W}_{\text{net,out}} = \dot{n} W_{\text{net,out}} = (3500/60 \text{ rev/s})(1.501 \text{ kJ/rev}) = \mathbf{87.5 \text{ kW}}$$

Discussion Note that for 2-stroke engines, 1 thermodynamic cycle is equivalent to 1 mechanical cycle (and thus revolutions).

9-59E An ideal dual cycle has a compression ratio of 15 and cutoff ratio of 1.4. The net work, heat addition, and the thermal efficiency are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $R = 0.3704 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R}$ (Table A-1E), $c_p = 0.240 \text{ Btu}/\text{lbm} \cdot \text{R}$, $c_v = 0.171 \text{ Btu}/\text{lbm} \cdot \text{R}$, and $k = 1.4$ (Table A-2Ea).

Analysis Working around the cycle, the germane properties at the various states are

$$T_2 = T_1 \left(\frac{v_1}{v_2} \right)^{k-1} = T_1 r^{k-1} = (535 \text{ R})(15)^{1.4-1} = 1580 \text{ R}$$

$$P_2 = P_1 \left(\frac{v_1}{v_2} \right)^k = P_1 r^k = (14.2 \text{ psia})(15)^{1.4} = 629.2 \text{ psia}$$

$$P_x = P_3 = r_p P_2 = (1.1)(629.2 \text{ psia}) = 692.1 \text{ psia}$$

$$T_x = T_2 \left(\frac{P_x}{P_2} \right) = (1580 \text{ R}) \left(\frac{692.1 \text{ psia}}{629.2 \text{ psia}} \right) = 1738 \text{ R}$$

$$T_3 = T_x \left(\frac{v_3}{v_x} \right) = T_x r_c = (1738 \text{ R})(1.4) = 2433 \text{ R}$$

$$T_4 = T_3 \left(\frac{v_3}{v_4} \right)^{k-1} = T_3 \left(\frac{r_c}{r} \right)^{k-1} = (2433 \text{ R}) \left(\frac{1.4}{15} \right)^{1.4-1} = 942.2 \text{ R}$$

Applying the first law to each of the processes gives

$$w_{1-2} = c_v(T_2 - T_1) = (0.171 \text{ Btu}/\text{lbm} \cdot \text{R})(1580 - 535)\text{R} = 178.7 \text{ Btu}/\text{lbm}$$

$$q_{2-x} = c_v(T_x - T_2) = (0.171 \text{ Btu}/\text{lbm} \cdot \text{R})(1738 - 1580)\text{R} = 27.02 \text{ Btu}/\text{lbm}$$

$$q_{x-3} = c_p(T_3 - T_x) = (0.240 \text{ Btu}/\text{lbm} \cdot \text{R})(2433 - 1738)\text{R} = 166.8 \text{ Btu}/\text{lbm}$$

$$w_{x-3} = q_{x-3} - c_v(T_3 - T_x) = 166.8 \text{ Btu}/\text{lbm} - (0.171 \text{ Btu}/\text{lbm} \cdot \text{R})(2433 - 1738)\text{R} = 47.96 \text{ Btu}/\text{lbm}$$

$$w_{3-4} = c_v(T_3 - T_4) = (0.171 \text{ Btu}/\text{lbm} \cdot \text{R})(2433 - 942.2)\text{R} = 254.9 \text{ Btu}/\text{lbm}$$

The net work of the cycle is

$$w_{\text{net}} = w_{3-4} + w_{x-3} - w_{1-2} = 254.9 + 47.96 - 178.7 = \mathbf{124.2 \text{ Btu}/\text{lbm}}$$

and the net heat addition is

$$q_{\text{in}} = q_{2-x} + q_{x-3} = 27.02 + 166.8 = \mathbf{193.8 \text{ Btu}/\text{lbm}}$$

Hence, the thermal efficiency is

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{124.2 \text{ Btu}/\text{lbm}}{193.8 \text{ Btu}/\text{lbm}} = \mathbf{0.641}$$

9-60 An ideal dual cycle with air as the working fluid has a compression ratio of 14. The fraction of heat transferred at constant volume and the thermal efficiency of the cycle are to be determined.

Assumptions **1** The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with variable specific heats.

Properties The properties of air are given in Table A-17.

Analysis (a) Process 1-2: isentropic compression.

$$T_1 = 300 \text{ K} \longrightarrow \begin{aligned} u_1 &= 214.07 \text{ kJ/kg} \\ v_{r_1} &= 621.2 \end{aligned}$$

$$v_{r_2} = \frac{v_2}{v_1} v_{r_1} = \frac{1}{r} v_{r_1} = \frac{1}{14} (621.2) = 44.37 \longrightarrow \begin{aligned} T_2 &= 823.1 \text{ K} \\ u_2 &= 611.2 \text{ kJ/kg} \end{aligned}$$

Process 2-x, x-3: heat addition,

$$T_3 = 2200 \text{ K} \longrightarrow \begin{aligned} h_3 &= 2503.2 \text{ kJ/kg} \\ v_{r_3} &= 2.012 \end{aligned}$$

$$\begin{aligned} q_{\text{in}} &= q_{2-x,\text{in}} + q_{3-x,\text{in}} = (u_x - u_2) + (h_3 - h_x) \\ 1520.4 &= (u_x - 611.2) + (2503.2 - h_x) \end{aligned}$$

By trial and error, we get

$$T_x = 1300 \text{ K} \text{ and } h_x = 1395.97, u_x = 1022.82 \text{ kJ/kg.}$$

Thus,

$$q_{2-x,\text{in}} = u_x - u_2 = 1022.82 - 611.2 = 411.62 \text{ kJ/kg}$$

and

$$\text{ratio} = \frac{q_{2-x,\text{in}}}{q_{\text{in}}} = \frac{411.62 \text{ kJ/kg}}{1520.4 \text{ kJ/kg}} = \mathbf{27.1\%}$$

$$(b) \quad \frac{P_3 v_3}{T_3} = \frac{P_x v_x}{T_x} \longrightarrow \frac{v_3}{v_x} = \frac{T_3}{T_x} = \frac{2200 \text{ K}}{1300 \text{ K}} = 1.692 = r_c$$

$$v_{r_4} = \frac{v_4}{v_3} v_{r_3} = \frac{v_4}{1.692 v_3} v_{r_3} = \frac{r}{1.692} v_{r_3} = \frac{14}{1.692} (2.012) = 16.648 \longrightarrow u_4 = 886.3 \text{ kJ/kg}$$

Process 4-1: $v = \text{constant}$ heat rejection.

$$q_{\text{out}} = u_4 - u_1 = 886.3 - 214.07 = 672.23 \text{ kJ/kg}$$

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{672.23 \text{ kJ/kg}}{1520.4 \text{ kJ/kg}} = \mathbf{55.8\%}$$

9-61 Problem 9-60 is reconsidered. The effect of the compression ratio on the net work output and thermal efficiency is to be investigated. Also, T - s and P - v diagrams for the cycle are to be plotted.

Analysis Using EES, the problem is solved as follows:

"Input Data"

T[1]=300 [K]
 P[1]=100 [kPa]

9-62 An ideal dual cycle with air as the working fluid has a compression ratio of 14. The fraction of heat transferred at constant volume and the thermal efficiency of the cycle are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2).

Analysis (a) Process 1-2: isentropic compression.

$$T_2 = T_1 \left(\frac{v_1}{v_2} \right)^{k-1} = (300 \text{ K})(14)^{0.4} = 862 \text{ K}$$

Process 2- x , x -3: heat addition,

$$\begin{aligned} q_{\text{in}} &= q_{2-x,\text{in}} + q_{3-x,\text{in}} = (u_x - u_2) + (h_3 - h_x) \\ &= c_v(T_x - T_2) + c_p(T_3 - T_x) \\ 1520.4 \text{ kJ/kg} &= (0.718 \text{ kJ/kg}\cdot\text{K})(T_x - 862) + (1.005 \text{ kJ/kg}\cdot\text{K})(2200 - T_x) \end{aligned}$$

Solving for T_x we get $T_x = 250 \text{ K}$ which is impossible. Therefore, constant specific heats at room temperature turned out to be an unreasonable assumption in this case because of the very high temperatures involved.

9-63 An expression for cutoff ratio of an ideal diesel cycle is to be developed.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Analysis Employing the isentropic process equations,

$$T_2 = T_1 r^{k-1}$$

while the ideal gas law gives

$$T_3 = T_2 r_c = r_c r^{k-1} T_1$$

When the first law and the closed system work integral is applied to the constant pressure heat addition, the result is

$$q_{\text{in}} = c_p(T_3 - T_2) = c_p(r_c r^{k-1} T_1 - r^{k-1} T_1)$$

When this is solved for cutoff ratio, the result is

$$r_c = 1 + \frac{q_{\text{in}}}{c_p r^{k-1} T_1}$$

9-64 The five processes of the dual cycle is described. The P - v and T - s diagrams for this cycle is to be sketched. An expression for the cycle thermal efficiency is to be obtained and the limit of the efficiency is to be evaluated for certain cases.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Analysis (a) The P - v and T - s diagrams for this cycle are as shown.

(b) Apply first law to the closed system for processes 2-3, 3-4, and 5-1 to show:

$$q_{in} = C_v(T_3 - T_2) + C_p(T_4 - T_3)$$

$$q_{out} = C_v(T_5 - T_1)$$

The cycle thermal efficiency is given by

$$\eta_{th} = 1 - \frac{q_{out}}{q_{in}} = 1 - \frac{C_v(T_5 - T_1)}{C_v(T_3 - T_2) + C_p(T_4 - T_3)} = 1 - \frac{T_1(T_5/T_1 - 1)}{T_2(T_3/T_2 - 1) + kT_3(T_4/T_3 - 1)}$$

$$\eta_{th} = 1 - \frac{(T_5/T_1 - 1)}{\frac{T_2}{T_1}(T_3/T_2 - 1) + k\frac{T_3}{T_1}(T_4/T_3 - 1)}$$

Process 1-2 is isentropic; therefore,

$$\frac{T_2}{T_1} = \left(\frac{V_1}{V_2}\right)^{k-1} = r^{k-1}$$

Process 2-3 is constant volume; therefore,

$$\frac{T_3}{T_2} = \frac{P_3 V_3}{P_2 V_2} = \frac{P_3}{P_2} = r_p$$

Process 3-4 is constant pressure; therefore,

$$\frac{P_4 V_4}{T_4} = \frac{P_3 V_3}{T_3} \Rightarrow \frac{T_4}{T_3} = \frac{V_4}{V_3} = r_c$$

Process 4-5 is isentropic; therefore,

$$\frac{T_5}{T_4} = \left(\frac{V_4}{V_5}\right)^{k-1} = \left(\frac{V_4}{V_1}\right)^{k-1} = \left(\frac{r_c V_3}{V_1}\right)^{k-1} = \left(\frac{r_c V_2}{V_1}\right)^{k-1} = \left(\frac{r_c}{r}\right)^{k-1}$$

Process 5-1 is constant volume; however T_5/T_1 is found from the following.

$$\frac{T_5}{T_1} = \frac{T_5}{T_4} \frac{T_4}{T_3} \frac{T_3}{T_2} \frac{T_2}{T_1} = \left(\frac{r_c}{r}\right)^{k-1} r_c r_p r^{k-1} = r_c^k r_p$$

The ratio T_3/T_1 is found from the following.

$$\frac{T_3}{T_1} = \frac{T_3}{T_2} \frac{T_2}{T_1} = r_p r^{k-1}$$

The efficiency becomes

$$\eta_{th} = 1 - \frac{r_c^k r_p - 1}{r^{k-1} (r_p - 1) + k r_p r^{k-1} (r_c - 1)}$$

(c) In the limit as r_p approaches unity, the cycle thermal efficiency becomes

$$\lim_{r_p \rightarrow 1} \eta_{th} = 1 - \left\{ \lim_{r_p \rightarrow 1} \frac{r_c^k r_p - 1}{r^{k-1} (r_p - 1) + k r_p r^{k-1} (r_c - 1)} \right\}$$

$$\lim_{r_p \rightarrow 1} \eta_{th} = 1 - \frac{1}{r^{k-1}} \left[\frac{r_c^k - 1}{k (r_c - 1)} \right] = \eta_{th \text{ Diesel}}$$

(d) In the limit as r_c approaches unity, the cycle thermal efficiency becomes

$$\lim_{r_c \rightarrow 1} \eta_{th} = 1 - \left\{ \lim_{r_c \rightarrow 1} \frac{r_c^k r_p - 1}{r^{k-1} (r_p - 1) + k r_p r^{k-1} (r_c - 1)} \right\} = 1 - \left\{ \frac{r_p - 1}{r^{k-1} (r_p - 1)} \right\}$$

$$\lim_{r_c \rightarrow 1} \eta_{th} = 1 - \frac{1}{r^{k-1}} = \eta_{th \text{ Otto}}$$

Stirling and Ericsson Cycles

9-65C The Stirling cycle.

9-66C The two isentropic processes of the Carnot cycle are replaced by two constant pressure regeneration processes in the Ericsson cycle.

9-67C The efficiencies of the Carnot and the Stirling cycles would be the same, the efficiency of the Otto cycle would be less.

9-68C The efficiencies of the Carnot and the Ericsson cycles would be the same, the efficiency of the Diesel cycle would be less.

9-69E An ideal Ericsson engine with helium as the working fluid operates between the specified temperature and pressure limits. The thermal efficiency of the cycle, the heat transfer rate in the regenerator, and the power delivered are to be determined.

Assumptions Helium is an ideal gas with constant specific heats.

Properties The gas constant and the specific heat of helium at room temperature are $R = 0.4961 \text{ Btu/lbm}\cdot\text{R}$ and $c_p = 1.25 \text{ Btu/lbm}\cdot\text{R}$ (Table A-2E).

Analysis (a) The thermal efficiency of this totally reversible cycle is determined from

$$\eta_{\text{th}} = 1 - \frac{T_L}{T_H} = 1 - \frac{550\text{R}}{3000\text{R}} = \mathbf{81.67\%}$$

(b) The amount of heat transferred in the regenerator is

$$\begin{aligned}\dot{Q}_{\text{regen}} &= \dot{Q}_{41,\text{in}} = \dot{m}(h_1 - h_4) = \dot{m}c_p(T_1 - T_4) \\ &= (14 \text{ lbm/s})(1.25 \text{ Btu/lbm}\cdot\text{R})(3000 - 550)\text{R} \\ &= \mathbf{42,875 \text{ Btu/s}}\end{aligned}$$

(c) The net power output is determined from

$$s_2 - s_1 = c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} = -(0.4961 \text{ Btu/lbm}\cdot\text{R}) \ln \frac{25 \text{ psia}}{200 \text{ psia}} = 1.0316 \text{ Btu/lbm}\cdot\text{R}$$

$$\dot{Q}_{\text{in}} = \dot{m}T_H(s_2 - s_1) = (14 \text{ lbm/s})(3000 \text{ R})(1.0316 \text{ Btu/lbm}\cdot\text{R}) = 43,328 \text{ Btu/s}$$

$$\dot{W}_{\text{net,out}} = \eta_{\text{th}} \dot{Q}_{\text{in}} = (0.8167)(43,328) = \mathbf{35,384 \text{ Btu/s}}$$

9-70 An ideal Stirling engine with helium as the working fluid operates between the specified temperature and pressure limits. The thermal efficiency of the cycle, the amount of heat transfer in the regenerator, and the work output per cycle are to be determined.

Assumptions Helium is an ideal gas with constant specific heats.

Properties The gas constant and the specific heat of helium at room temperature are $R = 2.0769 \text{ kJ/kg}\cdot\text{K}$, $c_v = 3.1156 \text{ kJ/kg}\cdot\text{K}$ and $c_p = 5.1926 \text{ kJ/kg}\cdot\text{K}$ (Table A-2).

Analysis (a) The thermal efficiency of this totally reversible cycle is determined from

$$\eta_{\text{th}} = 1 - \frac{T_L}{T_H} = 1 - \frac{300 \text{ K}}{2000 \text{ K}} = \mathbf{85.0\%}$$

(b) The amount of heat transferred in the regenerator is

$$\begin{aligned} Q_{\text{regen}} &= Q_{41\text{in}} = m(u_1 - u_4) = mc_v(T_1 - T_4) \\ &= (0.12 \text{ kg})(3.1156 \text{ kJ/kg}\cdot\text{K})(2000 - 300)\text{K} \\ &= \mathbf{635.6 \text{ kJ}} \end{aligned}$$

(c) The net work output is determined from

$$\begin{aligned} \frac{P_3 v_3}{T_3} &= \frac{P_1 v_1}{T_1} \longrightarrow \frac{v_3}{v_1} = \frac{T_3 P_1}{T_1 P_3} = \frac{(300 \text{ K})(3000 \text{ kPa})}{(2000 \text{ K})(150 \text{ kPa})} = 3 = \frac{v_2}{v_1} \\ s_2 - s_1 &= c_v \ln \frac{T_2}{T_1} + R \ln \frac{v_2}{v_1} = (2.0769 \text{ kJ/kg}\cdot\text{K}) \ln(3) = 2.282 \text{ kJ/kg}\cdot\text{K} \\ Q_{\text{in}} &= mT_H(s_2 - s_1) = (0.12 \text{ kg})(2000 \text{ K})(2.282 \text{ kJ/kg}\cdot\text{K}) = 547.6 \text{ kJ} \\ W_{\text{net,out}} &= \eta_{\text{th}} Q_{\text{in}} = (0.85)(547.6 \text{ kJ}) = \mathbf{465.5 \text{ kJ}} \end{aligned}$$

9-71 An ideal steady-flow Ericsson engine with air as the working fluid is considered. The maximum pressure in the cycle, the net work output, and the thermal efficiency of the cycle are to be determined.

Assumptions Air is an ideal gas.

Properties The gas constant of air is $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ (Table A-1).

Analysis (a) The entropy change during process 3-4 is

$$s_4 - s_3 = -\frac{q_{34,\text{out}}}{T_0} = -\frac{150 \text{ kJ/kg}}{300 \text{ K}} = -0.5 \text{ kJ/kg}\cdot\text{K}$$

and

$$\begin{aligned} s_4 - s_3 &= c_p \ln \frac{T_4}{T_3} - R \ln \frac{P_4}{P_3} \\ &= -(0.287 \text{ kJ/kg}\cdot\text{K}) \ln \frac{P_4}{120 \text{ kPa}} = -0.5 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

It yields $P_4 = \mathbf{685.2 \text{ kPa}}$

(b) For reversible cycles,

$$\frac{q_{\text{out}}}{q_{\text{in}}} = \frac{T_L}{T_H} \longrightarrow q_{\text{in}} = \frac{T_H}{T_L} q_{\text{out}} = \frac{1200 \text{ K}}{300 \text{ K}} (150 \text{ kJ/kg}) = 600 \text{ kJ/kg}$$

Thus,

$$w_{\text{net,out}} = q_{\text{in}} - q_{\text{out}} = 600 - 150 = \mathbf{450 \text{ kJ/kg}}$$

(c) The thermal efficiency of this totally reversible cycle is determined from

$$\eta_{\text{th}} = 1 - \frac{T_L}{T_H} = 1 - \frac{300 \text{ K}}{1200 \text{ K}} = \mathbf{75.0\%}$$

9-72E An ideal Stirling engine with air as the working fluid is considered. The temperature of the source-energy reservoir, the amount of air contained in the engine, and the maximum air pressure during the cycle are to be determined.

Assumptions Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $R = 0.3704 \text{ psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R}$ (Table A-1E), $c_p = 0.240 \text{ Btu/lbm}\cdot\text{R}$, $c_v = 0.171 \text{ Btu/lbm}\cdot\text{R}$, and $k = 1.4$ (Table A-2Ea).

Analysis From the thermal efficiency relation,

$$\eta_{\text{th}} = \frac{W_{\text{net}}}{Q_{\text{in}}} = 1 - \frac{T_L}{T_H} \longrightarrow \frac{2 \text{ Btu}}{5 \text{ Btu}} = 1 - \frac{535 \text{ R}}{T_H} \longrightarrow T_H = \mathbf{891.7 \text{ R}}$$

State 3 may be used to determine the mass of air in the system,

$$m = \frac{P_3 V_3}{RT_3} = \frac{(15 \text{ psia})(0.5 \text{ ft}^3)}{(0.3704 \text{ psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R})(535 \text{ R})} = \mathbf{0.03785 \text{ lbm}}$$

The maximum pressure occurs at state 1,

$$P_1 = \frac{mRT_1}{V_1} = \frac{(0.03785 \text{ lbm})(0.3704 \text{ psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R})(891.7 \text{ R})}{0.06 \text{ ft}^3} = \mathbf{208.3 \text{ psia}}$$

9-73E An ideal Stirling engine with air as the working fluid is considered. The temperature of the source-energy reservoir, the amount of air contained in the engine, and the maximum air pressure during the cycle are to be determined.

Assumptions Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $R = 0.3704 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R}$, $c_p = 0.240 \text{ Btu}/\text{lbm} \cdot \text{R}$, $c_v = 0.171 \text{ Btu}/\text{lbm} \cdot \text{R}$, and $k = 1.4$ (Table A-2E).

Analysis From the thermal efficiency relation,

$$\eta_{\text{th}} = \frac{W_{\text{net}}}{Q_{\text{in}}} = 1 - \frac{T_L}{T_H} \longrightarrow \frac{2.5 \text{ Btu}}{5 \text{ Btu}} = 1 - \frac{535 \text{ R}}{T_H} \longrightarrow T_H = \mathbf{1070 \text{ R}}$$

State 3 may be used to determine the mass of air in the system,

$$m = \frac{P_3 V_3}{RT_3} = \frac{(15 \text{ psia})(0.5 \text{ ft}^3)}{(0.3704 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(535 \text{ R})} = \mathbf{0.03785 \text{ lbm}}$$

The maximum pressure occurs at state 1,

$$P_1 = \frac{mRT_1}{V_1} = \frac{(0.03785 \text{ lbm})(0.3704 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(1070 \text{ R})}{0.06 \text{ ft}^3} = \mathbf{250 \text{ psia}}$$

9-74 An ideal Stirling engine with air as the working fluid operates between specified pressure limits. The heat added to the cycle and the net work produced by the cycle are to be determined.

Assumptions Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $R = 0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K}$, $c_p = 1.005 \text{ kJ}/\text{kg} \cdot \text{K}$, $c_v = 0.718 \text{ kJ}/\text{kg} \cdot \text{K}$, and $k = 1.4$ (Table A-2a).

Analysis Applying the ideal gas equation to the isothermal process 3-4 gives

$$P_4 = P_3 \frac{v_3}{v_4} = (50 \text{ kPa})(12) = 600 \text{ kPa}$$

Since process 4-1 is one of constant volume,

$$T_1 = T_4 \left(\frac{P_1}{P_4} \right) = (298 \text{ K}) \left(\frac{3600 \text{ kPa}}{600 \text{ kPa}} \right) = 1788 \text{ K}$$

Adapting the first law and work integral to the heat addition process gives

$$q_{\text{in}} = w_{1-2} = RT_1 \ln \frac{v_2}{v_1} = (0.287 \text{ kJ}/\text{kg} \cdot \text{K})(1788 \text{ K}) \ln(12) = \mathbf{1275 \text{ kJ}/\text{kg}}$$

Similarly,

$$q_{\text{out}} = w_{3-4} = RT_3 \ln \frac{v_4}{v_3} = (0.287 \text{ kJ}/\text{kg} \cdot \text{K})(298 \text{ K}) \ln \left(\frac{1}{12} \right) = \mathbf{212.5 \text{ kJ}/\text{kg}}$$

The net work is then

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 1275 - 212.5 = \mathbf{1063 \text{ kJ}/\text{kg}}$$

9-75 An ideal Stirling engine with air as the working fluid operates between specified pressure limits. The heat transfer in the regenerator is to be determined.

Assumptions Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $R = 0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K}$, $c_p = 1.005 \text{ kJ/kg} \cdot \text{K}$, $c_v = 0.718 \text{ kJ/kg} \cdot \text{K}$, and $k = 1.4$ (Table A-2a).

Analysis Applying the ideal gas equation to the isothermal process 3-4 gives

$$P_4 = P_3 \frac{v_3}{v_4} = (50 \text{ kPa})(12) = 600 \text{ kPa}$$

Since process 4-1 is one of constant volume,

$$T_1 = T_4 \left(\frac{P_1}{P_4} \right) = (298 \text{ K}) \left(\frac{3600 \text{ kPa}}{600 \text{ kPa}} \right) = 1788 \text{ K}$$

Application of the first law to process 4-1 gives

$$q_{\text{regen}} = c_v(T_1 - T_4) = (0.718 \text{ kJ/kg} \cdot \text{K})(1788 - 298) \text{ K} = \mathbf{1070 \text{ kJ/kg}}$$

Ideal and Actual Gas-Turbine (Brayton) Cycles

9-76C For fixed maximum and minimum temperatures, (a) the thermal efficiency increases with pressure ratio, (b) the net work first increases with pressure ratio, reaches a maximum, and then decreases.

9-77C Back work ratio is the ratio of the compressor (or pump) work input to the turbine work output. It is usually between 0.40 and 0.6 for gas turbine engines.

9-78C In gas turbine engines a gas is compressed, and thus the compression work requirements are very large since the steady-flow work is proportional to the specific volume.

9-79C As a result of turbine and compressor inefficiencies, (a) the back work ratio increases, and (b) the thermal efficiency decreases.

9-80E A simple ideal Brayton cycle with air as the working fluid has a pressure ratio of 10. The air temperature at the compressor exit, the back work ratio, and the thermal efficiency are to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with variable specific heats.

Properties The properties of air are given in Table A-17E.

Analysis (a) Noting that process 1-2 is isentropic,

$$T_1 = 520 \text{ R} \longrightarrow \begin{array}{l} h_1 = 124.27 \text{ Btu/lbm} \\ P_{r_1} = 1.2147 \end{array}$$

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = (10)(1.2147) = 12.147 \longrightarrow \begin{array}{l} T_2 = \mathbf{996.5 \text{ R}} \\ h_2 = 240.11 \text{ Btu/lbm} \end{array}$$

(b) Process 3-4 is isentropic, and thus

$$T_3 = 2000 \text{ R} \longrightarrow \begin{array}{l} h_3 = 504.71 \text{ Btu/lbm} \\ P_{r_3} = 174.0 \end{array}$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \left(\frac{1}{10}\right)(174.0) = 17.4 \longrightarrow h_4 = 265.83 \text{ Btu/lbm}$$

$$w_{C,\text{in}} = h_2 - h_1 = 240.11 - 124.27 = 115.84 \text{ Btu/lbm}$$

$$w_{T,\text{out}} = h_3 - h_4 = 504.71 - 265.83 = 238.88 \text{ Btu/lbm}$$

Then the back-work ratio becomes

$$r_{\text{bw}} = \frac{w_{C,\text{in}}}{w_{T,\text{out}}} = \frac{115.84 \text{ Btu/lbm}}{238.88 \text{ Btu/lbm}} = \mathbf{48.5\%}$$

(c) $q_{\text{in}} = h_3 - h_2 = 504.71 - 240.11 = 264.60 \text{ Btu/lbm}$

$$w_{\text{net,out}} = w_{T,\text{out}} - w_{C,\text{in}} = 238.88 - 115.84 = 123.04 \text{ Btu/lbm}$$

$$\eta_{\text{th}} = \frac{w_{\text{net,out}}}{q_{\text{in}}} = \frac{123.04 \text{ Btu/lbm}}{264.60 \text{ Btu/lbm}} = \mathbf{46.5\%}$$

9-81 A 32-MW gas-turbine power plant operates on a simple Brayton cycle with air as the working fluid. The mass flow rate of air through the cycle is to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with variable specific heats.

Properties The properties of air are given in Table A-17.

Analysis Using variable specific heats,

$$T_1 = 310 \text{ K} \longrightarrow \begin{aligned} h_1 &= 310.24 \text{ kJ/kg} \\ P_{r_1} &= 1.5546 \end{aligned}$$

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = (8)(1.5546) = 12.44 \longrightarrow h_{2s} = 562.26 \text{ kJ/kg}$$

$$T_3 = 900 \text{ K} \longrightarrow \begin{aligned} h_3 &= 932.93 \text{ kJ/kg} \\ P_{r_3} &= 75.29 \end{aligned}$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \left(\frac{1}{8}\right)(75.29) = 9.411 \longrightarrow h_{4s} = 519.32 \text{ kJ/kg}$$

$$\begin{aligned} w_{\text{net,out}} &= w_{T,\text{out}} - w_{C,\text{in}} = \eta_T (h_3 - h_{4s}) - (h_{2s} - h_1) / \eta_C \\ &= (0.86)(932.93 - 519.32) - (562.26 - 310.24) / (0.80) \\ &= 40.68 \text{ kJ/kg} \end{aligned}$$

and

$$\dot{m} = \frac{\dot{W}_{\text{net,out}}}{w_{\text{net,out}}} = \frac{32,000 \text{ kJ/s}}{40.68 \text{ kJ/kg}} = \mathbf{786.6 \text{ kg/s}}$$

9-82 A 32-MW gas-turbine power plant operates on a simple Brayton cycle with air as the working fluid. The mass flow rate of air through the cycle is to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2).

Analysis Using constant specific heats,

$$T_{2s} = T_1 \left(\frac{P_2}{P_1}\right)^{(k-1)/k} = (310 \text{ K})(8)^{0.4/1.4} = 561.5 \text{ K}$$

$$T_{4s} = T_3 \left(\frac{P_4}{P_3}\right)^{(k-1)/k} = (900 \text{ K})\left(\frac{1}{8}\right)^{0.4/1.4} = 496.8 \text{ K}$$

$$\begin{aligned} w_{\text{net,out}} &= w_{T,\text{out}} - w_{C,\text{in}} = \eta_T c_p (T_3 - T_{4s}) - c_p (T_{2s} - T_1) / \eta_C \\ &= (1.005 \text{ kJ/kg}\cdot\text{K})[(0.86)(900 - 496.8) - (561.5 - 310) / (0.80)] \text{ K} \\ &= 32.5 \text{ kJ/kg} \end{aligned}$$

and

$$\dot{m} = \frac{\dot{W}_{\text{net,out}}}{w_{\text{net,out}}} = \frac{32,000 \text{ kJ/s}}{32.5 \text{ kJ/kg}} = \mathbf{984.6 \text{ kg/s}}$$

9-83 A simple Brayton cycle with air as the working fluid has a pressure ratio of 10. The air temperature at the turbine exit, the net work output, and the thermal efficiency are to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with variable specific heats.

Properties The properties of air are given in Table A-17.

Analysis (a) Noting that process 1-2s is isentropic,

$$T_1 = 295 \text{ K} \longrightarrow \begin{aligned} h_1 &= 295.17 \text{ kJ/kg} \\ P_{r_1} &= 1.3068 \end{aligned}$$

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = (10)(1.3068) = 13.07 \longrightarrow h_{2s} = 570.26 \text{ kJ/kg} \text{ and } T_{2s} = 564.9 \text{ K}$$

$$\begin{aligned} \eta_C &= \frac{h_{2s} - h_1}{h_2 - h_1} \longrightarrow h_2 = h_1 + \frac{h_{2s} - h_1}{\eta_C} \\ &= 295.17 + \frac{570.26 - 295.17}{0.83} = 626.60 \text{ kJ/kg} \end{aligned}$$

$$T_3 = 1240 \text{ K} \longrightarrow \begin{aligned} h_3 &= 1324.93 \text{ kJ/kg} \\ P_{r_3} &= 272.3 \end{aligned}$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \left(\frac{1}{10}\right)(272.3) = 27.23 \longrightarrow h_{4s} = 702.07 \text{ kJ/kg} \text{ and } T_{4s} = 689.6 \text{ K}$$

$$\begin{aligned} \eta_T &= \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow h_4 = h_3 - \eta_T(h_3 - h_{4s}) \\ &= 1324.93 - (0.87)(1324.93 - 702.07) \\ &= 783.04 \text{ kJ/kg} \end{aligned}$$

Thus,

$$T_4 = \mathbf{764.4 \text{ K}}$$

$$(b) \quad q_{in} = h_3 - h_2 = 1324.93 - 626.60 = 698.3 \text{ kJ/kg}$$

$$q_{out} = h_4 - h_1 = 783.04 - 295.17 = 487.9 \text{ kJ/kg}$$

$$w_{net,out} = q_{in} - q_{out} = 698.3 - 487.9 = \mathbf{210.4 \text{ kJ/kg}}$$

$$(c) \quad \eta_{th} = \frac{w_{net,out}}{q_{in}} = \frac{210.4 \text{ kJ/kg}}{698.3 \text{ kJ/kg}} = 0.3013 = \mathbf{30.1\%}$$

9-84 Problem 9-83 is reconsidered. The mass flow rate, pressure ratio, turbine inlet temperature, and the isentropic efficiencies of the turbine and compressor are to be varied and a general solution for the problem by taking advantage of the diagram window method for supplying data to EES is to be developed.

Analysis Using EES, the problem is solved as follows:

"Input data - from diagram window"

```
{P_ratio = 10}
{T[1] = 295 [K]
P[1]= 100 [kPa]

9-85 A simple Brayton cycle with air as the working fluid has a pressure ratio of 10. The air temperature at the turbine exit, the net work output, and the thermal efficiency are to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2).

Analysis (a) Using the compressor and turbine efficiency relations,

$$T_{2s} = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (295 \text{ K})(10)^{0.4/1.4} = 569.6 \text{ K}$$

$$T_{4s} = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = (1240 \text{ K}) \left(\frac{1}{10} \right)^{0.4/1.4} = 642.3 \text{ K}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} = \frac{c_p(T_{2s} - T_1)}{c_p(T_2 - T_1)} \longrightarrow T_2 = T_1 + \frac{T_{2s} - T_1}{\eta_C}$$

$$= 295 + \frac{569.6 - 295}{0.83} = 625.8 \text{ K}$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} = \frac{c_p(T_3 - T_4)}{c_p(T_3 - T_{4s})} \longrightarrow T_4 = T_3 - \eta_T(T_3 - T_{4s})$$

$$= 1240 - (0.87)(1240 - 642.3)$$

$$= \mathbf{720 \text{ K}}$$

$$(b) \quad q_{in} = h_3 - h_2 = c_p(T_3 - T_2) = (1.005 \text{ kJ/kg}\cdot\text{K})(1240 - 625.8)\text{K} = 617.3 \text{ kJ/kg}$$

$$q_{out} = h_4 - h_1 = c_p(T_4 - T_1) = (1.005 \text{ kJ/kg}\cdot\text{K})(720 - 295)\text{K} = 427.1 \text{ kJ/kg}$$

$$w_{net,out} = q_{in} - q_{out} = 617.3 - 427.1 = \mathbf{190.2 \text{ kJ/kg}}$$

$$(c) \quad \eta_{th} = \frac{w_{net,out}}{q_{in}} = \frac{190.2 \text{ kJ/kg}}{617.3 \text{ kJ/kg}} = 0.3081 = \mathbf{30.8\%}$$

9-86 A simple Brayton cycle with air as the working fluid operates between the specified temperature and pressure limits. The effects of non-isentropic compressor and turbine on the back-work ratio is to be compared.

Assumptions 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2a).

Analysis For the compression process,

$$T_{2s} = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (288 \text{ K})(12)^{0.4/1.4} = 585.8 \text{ K}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} = \frac{c_p(T_{2s} - T_1)}{c_p(T_2 - T_1)} \longrightarrow T_2 = T_1 + \frac{T_{2s} - T_1}{\eta_C}$$

$$= 288 + \frac{585.8 - 288}{0.80}$$

$$= 660.2 \text{ K}$$

For the expansion process,

$$T_{4s} = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = (873 \text{ K}) \left(\frac{1}{12} \right)^{0.4/1.4} = 429.2 \text{ K}$$

$$\eta_T = \frac{h_3 - h_{4s}}{h_3 - h_4} = \frac{c_p(T_3 - T_{4s})}{c_p(T_3 - T_4)} \longrightarrow T_4 = T_3 - \eta_T(T_3 - T_{4s})$$

$$= 873 - (0.80)(873 - 429.2)$$

$$= 518.0 \text{ K}$$

The isentropic and actual work of compressor and turbine are

$$W_{\text{Comp},s} = c_p(T_{2s} - T_1) = (1.005 \text{ kJ/kg}\cdot\text{K})(585.8 - 288) \text{ K} = 299.3 \text{ kJ/kg}$$

$$W_{\text{Comp}} = c_p(T_2 - T_1) = (1.005 \text{ kJ/kg}\cdot\text{K})(660.2 - 288) \text{ K} = 374.1 \text{ kJ/kg}$$

$$W_{\text{Turb},s} = c_p(T_3 - T_{4s}) = (1.005 \text{ kJ/kg}\cdot\text{K})(873 - 429.2) \text{ K} = 446.0 \text{ kJ/kg}$$

$$W_{\text{Turb}} = c_p(T_3 - T_4) = (1.005 \text{ kJ/kg}\cdot\text{K})(873 - 518.0) \text{ K} = 356.8 \text{ kJ/kg}$$

The back work ratio for 90% efficient compressor and isentropic turbine case is

$$r_{\text{bw}} = \frac{W_{\text{Comp}}}{W_{\text{Turb},s}} = \frac{374.1 \text{ kJ/kg}}{446.0 \text{ kJ/kg}} = \mathbf{0.8387}$$

The back work ratio for 90% efficient turbine and isentropic compressor case is

$$r_{\text{bw}} = \frac{W_{\text{Comp},s}}{W_{\text{Turb}}} = \frac{299.3 \text{ kJ/kg}}{356.8 \text{ kJ/kg}} = \mathbf{0.8387}$$

The two results are identical.

9-87 A gas turbine power plant that operates on the simple Brayton cycle with air as the working fluid has a specified pressure ratio. The required mass flow rate of air is to be determined for two cases.

Assumptions **1** Steady operating conditions exist. **2** The air-standard assumptions are applicable. **3** Kinetic and potential energy changes are negligible. **4** Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2).

Analysis (a) Using the isentropic relations,

$$T_{2s} = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (300 \text{ K})(12)^{0.4/1.4} = 610.2 \text{ K}$$

$$T_{4s} = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = (1000 \text{ K}) \left(\frac{1}{12} \right)^{0.4/1.4} = 491.7 \text{ K}$$

$$w_{s,C,in} = h_{2s} - h_1 = c_p (T_{2s} - T_1) = (1.005 \text{ kJ/kg}\cdot\text{K})(610.2 - 300) \text{ K} = 311.75 \text{ kJ/kg}$$

$$w_{s,T,out} = h_3 - h_{4s} = c_p (T_3 - T_{4s}) = (1.005 \text{ kJ/kg}\cdot\text{K})(1000 - 491.7) \text{ K} = 510.84 \text{ kJ/kg}$$

$$w_{s,net,out} = w_{s,T,out} - w_{s,C,in} = 510.84 - 311.75 = 199.1 \text{ kJ/kg}$$

$$\dot{m}_s = \frac{\dot{W}_{net,out}}{w_{s,net,out}} = \frac{70,000 \text{ kJ/s}}{199.1 \text{ kJ/kg}} = \mathbf{352 \text{ kg/s}}$$

(b) The net work output is determined to be

$$w_{a,net,out} = w_{a,T,out} - w_{a,C,in} = \eta_T w_{s,T,out} - w_{s,C,in} / \eta_C$$

$$= (0.85)(510.84) - 311.75 / 0.85 = 67.5 \text{ kJ/kg}$$

$$\dot{m}_a = \frac{\dot{W}_{net,out}}{w_{a,net,out}} = \frac{70,000 \text{ kJ/s}}{67.5 \text{ kJ/kg}} = \mathbf{1037 \text{ kg/s}}$$

9-88 An aircraft engine operates as a simple ideal Brayton cycle with air as the working fluid. The pressure ratio and the rate of heat input are given. The net power and the thermal efficiency are to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2a).

Analysis For the isentropic compression process,

$$T_2 = T_1 r_p^{(k-1)/k} = (273 \text{ K})(10)^{0.4/1.4} = 527.1 \text{ K}$$

The heat addition is

$$q_{\text{in}} = \frac{\dot{Q}_{\text{in}}}{\dot{m}} = \frac{500 \text{ kW}}{1 \text{ kg/s}} = 500 \text{ kJ/kg}$$

Applying the first law to the heat addition process,

$$q_{\text{in}} = c_p(T_3 - T_2)$$

$$T_3 = T_2 + \frac{q_{\text{in}}}{c_p} = 527.1 \text{ K} + \frac{500 \text{ kJ/kg}}{1.005 \text{ kJ/kg}\cdot\text{K}} = 1025 \text{ K}$$

The temperature at the exit of the turbine is

$$T_4 = T_3 \left(\frac{1}{r_p} \right)^{(k-1)/k} = (1025 \text{ K}) \left(\frac{1}{10} \right)^{0.4/1.4} = 530.9 \text{ K}$$

Applying the first law to the adiabatic turbine and the compressor produce

$$w_T = c_p(T_3 - T_4) = (1.005 \text{ kJ/kg}\cdot\text{K})(1025 - 530.9) \text{ K} = 496.6 \text{ kJ/kg}$$

$$w_C = c_p(T_2 - T_1) = (1.005 \text{ kJ/kg}\cdot\text{K})(527.1 - 273) \text{ K} = 255.4 \text{ kJ/kg}$$

The net power produced by the engine is then

$$\dot{W}_{\text{net}} = \dot{m}(w_T - w_C) = (1 \text{ kg/s})(496.6 - 255.4) \text{ kJ/kg} = \mathbf{241.2 \text{ kW}}$$

Finally the thermal efficiency is

$$\eta_{\text{th}} = \frac{\dot{W}_{\text{net}}}{\dot{Q}_{\text{in}}} = \frac{241.2 \text{ kW}}{500 \text{ kW}} = \mathbf{0.482}$$

9-89 An aircraft engine operates as a simple ideal Brayton cycle with air as the working fluid. The pressure ratio and the rate of heat input are given. The net power and the thermal efficiency are to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2a).

Analysis For the isentropic compression process,

$$T_2 = T_1 r_p^{(k-1)/k} = (273 \text{ K})(15)^{0.4/1.4} = 591.8 \text{ K}$$

The heat addition is

$$q_{\text{in}} = \frac{\dot{Q}_{\text{in}}}{\dot{m}} = \frac{500 \text{ kW}}{1 \text{ kg/s}} = 500 \text{ kJ/kg}$$

Applying the first law to the heat addition process,

$$q_{\text{in}} = c_p (T_3 - T_2)$$

$$T_3 = T_2 + \frac{q_{\text{in}}}{c_p} = 591.8 \text{ K} + \frac{500 \text{ kJ/kg}}{1.005 \text{ kJ/kg}\cdot\text{K}} = 1089 \text{ K}$$

The temperature at the exit of the turbine is

$$T_4 = T_3 \left(\frac{1}{r_p} \right)^{(k-1)/k} = (1089 \text{ K}) \left(\frac{1}{15} \right)^{0.4/1.4} = 502.3 \text{ K}$$

Applying the first law to the adiabatic turbine and the compressor produce

$$w_T = c_p (T_3 - T_4) = (1.005 \text{ kJ/kg}\cdot\text{K})(1089 - 502.3) \text{ K} = 589.6 \text{ kJ/kg}$$

$$w_C = c_p (T_2 - T_1) = (1.005 \text{ kJ/kg}\cdot\text{K})(591.8 - 273) \text{ K} = 320.4 \text{ kJ/kg}$$

The net power produced by the engine is then

$$\dot{W}_{\text{net}} = \dot{m}(w_T - w_C) = (1 \text{ kg/s})(589.6 - 320.4) \text{ kJ/kg} = \mathbf{269.2 \text{ kW}}$$

Finally the thermal efficiency is

$$\eta_{\text{th}} = \frac{\dot{W}_{\text{net}}}{\dot{Q}_{\text{in}}} = \frac{269.2 \text{ kW}}{500 \text{ kW}} = \mathbf{0.538}$$

9-90 A gas-turbine plant operates on the simple Brayton cycle. The net power output, the back work ratio, and the thermal efficiency are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with variable specific heats.

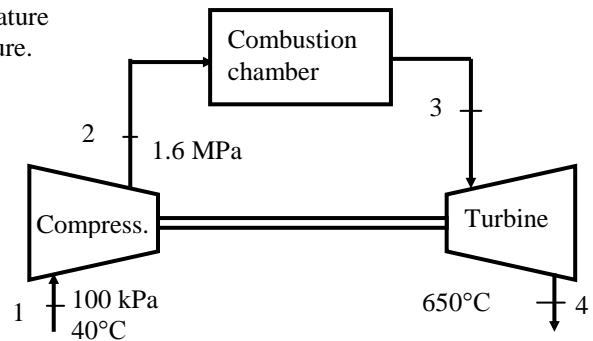

Properties The gas constant of air is $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ (Table A-1).

Analysis (a) For this problem, we use the properties from EES software.

Remember that for an ideal gas, enthalpy is a function of temperature only whereas entropy is functions of both temperature and pressure.

Process 1-2: Compression

$$\begin{aligned} T_1 &= 40^\circ\text{C} \longrightarrow h_1 = 313.6 \text{ kJ/kg} \\ \left. \begin{aligned} T_1 &= 40^\circ\text{C} \\ P_1 &= 100 \text{ kPa} \end{aligned} \right\} s_1 &= 5.749 \text{ kJ/kg}\cdot\text{K} \\ \left. \begin{aligned} P_2 &= 1600 \text{ kPa} \\ s_2 &= s_1 = 5.749 \text{ kJ/kg}\cdot\text{K} \end{aligned} \right\} h_{2s} &= 691.9 \text{ kJ/kg} \\ \eta_C &= \frac{h_{2s} - h_1}{h_2 - h_1} \longrightarrow 0.85 = \frac{691.9 - 313.6}{h_2 - 313.6} \longrightarrow h_2 = 758.6 \text{ kJ/kg} \end{aligned}$$

Process 3-4: Expansion

$$\begin{aligned} T_4 &= 650^\circ\text{C} \longrightarrow h_4 = 959.2 \text{ kJ/kg} \\ \eta_T &= \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow 0.88 = \frac{h_3 - 959.2}{h_3 - h_{4s}} \end{aligned}$$

We cannot find the enthalpy at state 3 directly. However, using the EES program, we find

$$h_3 = 1790 \text{ kJ/kg}, \quad T_3 = 1353^\circ\text{C}, \quad s_3 = 6.750 \text{ kJ/kg}\cdot\text{K}.$$

The solution by hand would require a trial-error approach. The mass flow rate is determined from

$$\dot{m} = \frac{P_1 \dot{V}_1}{RT_1} = \frac{(100 \text{ kPa})(850/60 \text{ m}^3/\text{s})}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(40 + 273 \text{ K})} = 15.77 \text{ kg/s}$$

The net power output is

$$\begin{aligned} \dot{W}_{C,\text{in}} &= \dot{m}(h_2 - h_1) = (15.77 \text{ kg/s})(758.6 - 313.6) \text{ kJ/kg} = 7017 \text{ kW} \\ \dot{W}_{T,\text{out}} &= \dot{m}(h_3 - h_4) = (15.77 \text{ kg/s})(1790 - 959.2) \text{ kJ/kg} = 13,098 \text{ kW} \\ \dot{W}_{\text{net}} &= \dot{W}_{T,\text{out}} - \dot{W}_{C,\text{in}} = 13,098 - 7017 = \mathbf{6081 \text{ kW}} \end{aligned}$$

(b) The back work ratio is

$$r_{\text{bw}} = \frac{\dot{W}_{C,\text{in}}}{\dot{W}_{T,\text{out}}} = \frac{7017 \text{ kW}}{13,098 \text{ kW}} = \mathbf{0.536}$$

(c) The rate of heat input and the thermal efficiency are

$$\begin{aligned} \dot{Q}_{\text{in}} &= \dot{m}(h_3 - h_2) = (15.77 \text{ kg/s})(1790 - 758.6) \text{ kJ/kg} = 16,262 \text{ kW} \\ \eta_{\text{th}} &= \frac{\dot{W}_{\text{net}}}{\dot{Q}_{\text{in}}} = \frac{6081 \text{ kW}}{16,262 \text{ kW}} = 0.374 = \mathbf{37.4\%} \end{aligned}$$

9-91E A gas-turbine power plant operates on a simple Brayton cycle with air as the working fluid. The net power output of the plant is to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with variable specific heats.

Properties The properties of air are given in Table A-17E.

Analysis Using variable specific heats for air,

$$T_3 = 2000 \text{ R} \longrightarrow h_3 = 504.71 \text{ Btu/lbm}$$

$$T_4 = 1200 \text{ R} \longrightarrow h_4 = 291.30 \text{ Btu/lbm}$$

$$r_p = \frac{P_2}{P_1} = \frac{120}{15} = 8$$

$$\dot{Q}_{\text{out}} = \dot{m}(h_4 - h_1) \longrightarrow h_1 = 291.30 - 6400/40 = 131.30 \text{ Btu/lbm}$$

$$\longrightarrow P_{r_1} = 1.474$$

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = (8)(1.474) = 11.79 \longrightarrow h_{2s} = 238.07 \text{ Btu/lbm}$$

$$\dot{W}_{C,\text{in}} = \dot{m}(h_{2s} - h_1) / \eta_C = (40 \text{ lbm/s})(238.07 - 131.30) / (0.80) = 5339 \text{ Btu/s}$$

$$\dot{W}_{T,\text{out}} = \dot{m}(h_3 - h_4) = (40 \text{ lbm/s})(504.71 - 291.30) \text{ Btu/lbm} = 8536 \text{ Btu/s}$$

$$\dot{W}_{\text{net,out}} = \dot{W}_{T,\text{out}} - \dot{W}_{C,\text{in}} = 8536 - 5339 = 3197 \text{ Btu/s} = \mathbf{3373 \text{ kW}}$$

9-92E A gas-turbine power plant operates on a simple Brayton cycle with air as the working fluid. The compressor efficiency for which the power plant produces zero net work is to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with variable specific heats.

Properties The properties of air are given in Table A-17E.

Analysis Using variable specific heats,

$$T_3 = 2000 \text{ R} \longrightarrow h_3 = 504.71 \text{ Btu/lbm}$$

$$T_4 = 1200 \text{ R} \longrightarrow h_4 = 291.30 \text{ Btu/lbm}$$

$$r_p = \frac{P_2}{P_1} = \frac{120}{15} = 8$$

$$\dot{Q}_{\text{out}} = \dot{m}(h_4 - h_1) \longrightarrow h_1 = 291.30 - 6400/40 = 131.30 \text{ Btu/lbm} \longrightarrow P_{r_1} = 1.474$$

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = (8)(1.474) = 11.79 \longrightarrow h_{2s} = 238.07 \text{ Btu/lbm}$$

Then, $\dot{W}_{C,\text{in}} = \dot{W}_{T,\text{out}} \longrightarrow \dot{m}(h_{2s} - h_1) / \eta_C = \dot{m}(h_3 - h_4)$

$$\eta_C = \frac{h_{2s} - h_1}{h_3 - h_4} = \frac{238.07 - 131.30}{504.71 - 291.30} = \mathbf{50.0\%}$$

9-93 A simple Brayton cycle with air as the working fluid operates between the specified temperature and pressure limits. The cycle is to be sketched on the T - s cycle and the isentropic efficiency of the turbine and the cycle thermal efficiency are to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with constant specific heats.

Properties The properties of air are given as $c_v = 0.718$ kJ/kg·K, $c_p = 1.005$ kJ/kg·K, $R = 0.287$ kJ/kg·K, $k = 1.4$.

Analysis (b) For the compression process,

$$\begin{aligned}\dot{W}_{\text{Comp}} &= \dot{m}c_p(T_2 - T_1) \\ &= (200 \text{ kg/s})(1.005 \text{ kJ/kg} \cdot \text{K})(330 - 30)\text{K} \\ &= 60,300 \text{ kW}\end{aligned}$$

For the turbine during the isentropic process,

$$T_{4s} = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = (1400 \text{ K}) \left(\frac{100 \text{ kPa}}{800 \text{ kPa}} \right)^{0.4/1.4} = 772.9 \text{ K}$$

$$\dot{W}_{\text{Turb},s} = \dot{m}c_p(T_3 - T_{4s}) = (200 \text{ kg/s})(1.005 \text{ kJ/kg} \cdot \text{K})(1400 - 772.9)\text{K} = 126,050 \text{ kW}$$

The actual power output from the turbine is

$$\begin{aligned}\dot{W}_{\text{net}} &= \dot{W}_{\text{Turb}} - \dot{W}_{\text{Comp}} \\ \dot{W}_{\text{Turb}} &= \dot{W}_{\text{net}} + \dot{W}_{\text{Comp}} = 60,000 + 60,300 = 120,300 \text{ kW}\end{aligned}$$

The isentropic efficiency of the turbine is then

$$\eta_{\text{Turb}} = \frac{\dot{W}_{\text{Turb}}}{\dot{W}_{\text{Turb},s}} = \frac{120,300 \text{ kW}}{126,050 \text{ kW}} = 0.954 = \mathbf{95.4\%}$$

(c) The rate of heat input is

$$\dot{Q}_{\text{in}} = \dot{m}c_p(T_3 - T_2) = (200 \text{ kg/s})(1.005 \text{ kJ/kg} \cdot \text{K})[(1400 - (330 + 273))\text{K}] = 160,200 \text{ kW}$$

The thermal efficiency is then

$$\eta_{\text{th}} = \frac{\dot{W}_{\text{net}}}{\dot{Q}_{\text{in}}} = \frac{60,000 \text{ kW}}{160,200 \text{ kW}} = 0.375 = \mathbf{37.5\%}$$

9-94 A modified Brayton cycle with air as the working fluid operates at a specified pressure ratio. The T - s diagram is to be sketched and the temperature and pressure at the exit of the high-pressure turbine and the mass flow rate of air are to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with constant specific heats.

Properties The properties of air are given as $c_v = 0.718$ kJ/kg·K, $c_p = 1.005$ kJ/kg·K, $R = 0.287$ kJ/kg·K, $k = 1.4$.

Analysis (b) For the compression process,

$$T_2 = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (273 \text{ K})(8)^{0.4/1.4} = 494.5 \text{ K}$$

The power input to the compressor is equal to the power output from the high-pressure turbine. Then,

$$\begin{aligned} \dot{W}_{\text{Comp, in}} &= \dot{W}_{\text{HP Turb, out}} \\ \dot{m} c_p (T_2 - T_1) &= \dot{m} c_p (T_3 - T_4) \\ T_2 - T_1 &= T_3 - T_4 \\ T_4 &= T_3 + T_1 - T_2 = 1500 + 273 - 494.5 = \mathbf{1278.5 \text{ K}} \end{aligned}$$

The pressure at this state is

$$\frac{P_4}{P_3} = \left(\frac{T_4}{T_3} \right)^{k/(k-1)} \longrightarrow P_4 = r P_1 \left(\frac{T_4}{T_3} \right)^{k/(k-1)} = 8(100 \text{ kPa}) \left(\frac{1278.5 \text{ K}}{1500 \text{ K}} \right)^{1.4/0.4} = \mathbf{457.3 \text{ kPa}}$$

(c) The temperature at state 5 is determined from

$$T_5 = T_4 \left(\frac{P_5}{P_4} \right)^{(k-1)/k} = (1278.5 \text{ K}) \left(\frac{100 \text{ kPa}}{457.3 \text{ kPa}} \right)^{0.4/1.4} = 828.1 \text{ K}$$

The net power is that generated by the low-pressure turbine since the power output from the high-pressure turbine is equal to the power input to the compressor. Then,

$$\begin{aligned} \dot{W}_{\text{LP Turb}} &= \dot{m} c_p (T_4 - T_5) \\ \dot{m} &= \frac{\dot{W}_{\text{LP Turb}}}{c_p (T_4 - T_5)} = \frac{200,000 \text{ kW}}{(1.005 \text{ kJ/kg} \cdot \text{K})(1278.5 - 828.1) \text{ K}} \\ &= \mathbf{441.8 \text{ kg/s}} \end{aligned}$$

Brayton Cycle with Regeneration

9-95C Regeneration increases the thermal efficiency of a Brayton cycle by capturing some of the waste heat from the exhaust gases and preheating the air before it enters the combustion chamber.

9-96C Yes. At very high compression ratios, the gas temperature at the turbine exit may be lower than the temperature at the compressor exit. Therefore, if these two streams are brought into thermal contact in a regenerator, heat will flow to the exhaust gases instead of from the exhaust gases. As a result, the thermal efficiency will decrease.

9-97C (b) turbine exit.

9-98C The steam injected increases the mass flow rate through the turbine and thus the power output. This, in turn, increases the thermal efficiency since $\eta = W / Q_{\text{in}}$ and W increases while Q_{in} remains constant. Steam can be obtained by utilizing the hot exhaust gases.

9-99 A Brayton cycle with regeneration produces 115 kW power. The rates of heat addition and rejection are to be determined.

Assumptions 1 The air standard assumptions are applicable. **2** Air is an ideal gas with constant specific heats at room temperature. **3** Kinetic and potential energy changes are negligible.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2a).

Analysis According to the isentropic process expressions for an ideal gas,

$$T_2 = T_1 r_p^{(k-1)/k} = (303 \text{ K})(10)^{0.4/1.4} = 585.0 \text{ K}$$

$$T_5 = T_4 \left(\frac{1}{r_p} \right)^{(k-1)/k} = (1073 \text{ K}) \left(\frac{1}{10} \right)^{0.4/1.4} = 555.8 \text{ K}$$

When the first law is applied to the heat exchanger, the result is

$$T_3 - T_2 = T_5 - T_6$$

while the regenerator temperature specification gives

$$T_3 = T_5 - 10 = 555.8 - 10 = 545.8 \text{ K}$$

The simultaneous solution of these two results gives

$$T_6 = T_5 - (T_3 - T_2) = 555.8 - (545.8 - 585.0) = 595.0 \text{ K}$$

Application of the first law to the turbine and compressor gives

$$\begin{aligned} w_{\text{net}} &= c_p (T_4 - T_5) - c_p (T_2 - T_1) \\ &= (1.005 \text{ kJ/kg}\cdot\text{K})(1073 - 555.8) \text{ K} - (1.005 \text{ kJ/kg}\cdot\text{K})(585.0 - 303) \text{ K} \\ &= 236.4 \text{ kJ/kg} \end{aligned}$$

Then,

$$\dot{m} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{115 \text{ kW}}{236.4 \text{ kJ/kg}} = 0.4864 \text{ kg/s}$$

Applying the first law to the combustion chamber produces

$$\dot{Q}_{\text{in}} = \dot{m} c_p (T_4 - T_3) = (0.4864 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(1073 - 545.8) \text{ K} = \mathbf{258 \text{ kW}}$$

Similarly,

$$\dot{Q}_{\text{out}} = \dot{m} c_p (T_6 - T_1) = (0.4864 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(595.0 - 303) \text{ K} = \mathbf{143 \text{ kW}}$$

9-100 A Brayton cycle with regeneration produces 115 kW power. The rates of heat addition and rejection are to be determined.

Assumptions 1 The air standard assumptions are applicable. **2** Air is an ideal gas with constant specific heats at room temperature. **3** Kinetic and potential energy changes are negligible.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2a).

Analysis For the compression and expansion processes we have

$$T_{2s} = T_1 r_p^{(k-1)/k} = (303 \text{ K})(10)^{0.4/1.4} = 585.0 \text{ K}$$

$$\eta_C = \frac{c_p(T_{2s} - T_1)}{c_p(T_2 - T_1)} \longrightarrow T_2 = T_1 + \frac{T_{2s} - T_1}{\eta_C}$$

$$= 303 + \frac{585.0 - 303}{0.87} = 627.1 \text{ K}$$

$$T_{5s} = T_4 \left(\frac{1}{r_p} \right)^{(k-1)/k} = (1073 \text{ K}) \left(\frac{1}{10} \right)^{0.4/1.4} = 555.8 \text{ K}$$

$$\eta_T = \frac{c_p(T_4 - T_5)}{c_p(T_4 - T_{5s})} \longrightarrow T_5 = T_4 - \eta_T(T_4 - T_{5s})$$

$$= 1073 - (0.93)(1073 - 555.8)$$

$$= 592.0 \text{ K}$$

When the first law is applied to the heat exchanger, the result is

$$T_3 - T_2 = T_5 - T_6$$

while the regenerator temperature specification gives

$$T_3 = T_5 - 10 = 592.0 - 10 = 582.0 \text{ K}$$

The simultaneous solution of these two results gives

$$T_6 = T_5 - (T_3 - T_2) = 592.0 - (582.0 - 627.1) = 637.1 \text{ K}$$

Application of the first law to the turbine and compressor gives

$$w_{\text{net}} = c_p(T_4 - T_5) - c_p(T_2 - T_1)$$

$$= (1.005 \text{ kJ/kg}\cdot\text{K})(1073 - 592.0) \text{ K} - (1.005 \text{ kJ/kg}\cdot\text{K})(627.1 - 303) \text{ K}$$

$$= 157.7 \text{ kJ/kg}$$

Then,

$$\dot{m} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{115 \text{ kW}}{157.7 \text{ kJ/kg}} = 0.7293 \text{ kg/s}$$

Applying the first law to the combustion chamber produces

$$\dot{Q}_{\text{in}} = \dot{m} c_p(T_4 - T_3) = (0.7293 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(1073 - 582.0) \text{ K} = \mathbf{360 \text{ kW}}$$

Similarly,

$$\dot{Q}_{\text{out}} = \dot{m} c_p(T_6 - T_1) = (0.7293 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(637.1 - 303) \text{ K} = \mathbf{245 \text{ kW}}$$

9-101 A Brayton cycle with regeneration is considered. The thermal efficiencies of the cycle for parallel-flow and counter-flow arrangements of the regenerator are to be compared.

Assumptions 1 The air standard assumptions are applicable. **2** Air is an ideal gas with constant specific heats at room temperature. **3** Kinetic and potential energy changes are negligible.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2a).

Analysis According to the isentropic process expressions for an ideal gas,

$$T_2 = T_1 r_p^{(k-1)/k} = (293 \text{ K})(7)^{0.4/1.4} = 510.9 \text{ K}$$

$$T_5 = T_4 \left(\frac{1}{r_p} \right)^{(k-1)/k} = (1000 \text{ K}) \left(\frac{1}{7} \right)^{0.4/1.4} = 573.5 \text{ K}$$

When the first law is applied to the heat exchanger as originally arranged, the result is

$$T_3 - T_2 = T_5 - T_6$$

while the regenerator temperature specification gives

$$T_3 = T_5 - 6 = 573.5 - 6 = 567.5 \text{ K}$$

The simultaneous solution of these two results gives

$$T_6 = T_5 - T_3 + T_2 = 573.5 - 567.5 + 510.9 = 516.9 \text{ K}$$

The thermal efficiency of the cycle is then

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{T_6 - T_1}{T_4 - T_3} = 1 - \frac{516.9 - 293}{1000 - 567.5} = \mathbf{0.482}$$

For the rearranged version of this cycle,

$$T_3 = T_6 - 6$$

An energy balance on the heat exchanger gives

$$T_3 - T_2 = T_5 - T_6$$

The solution of these two equations is

$$T_3 = 539.2 \text{ K}$$

$$T_6 = 545.2 \text{ K}$$

The thermal efficiency of the cycle is then

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{T_6 - T_1}{T_4 - T_3} = 1 - \frac{545.2 - 293}{1000 - 539.2} = \mathbf{0.453}$$

9-102E An ideal Brayton cycle with regeneration has a pressure ratio of 11. The thermal efficiency of the cycle is to be determined with and without regenerator cases.

Assumptions 1 The air standard assumptions are applicable. **2** Air is an ideal gas with constant specific heats at room temperature. **3** Kinetic and potential energy changes are negligible.

Properties The properties of air at room temperature are $c_p = 0.24$ Btu/lbm-R and $k = 1.4$ (Table A-2Ea).

Analysis According to the isentropic process expressions for an ideal gas,

$$T_2 = T_1 r_p^{(k-1)/k} = (560 \text{ R})(11)^{0.4/1.4} = 1111 \text{ R}$$

$$T_5 = T_4 \left(\frac{1}{r_p} \right)^{(k-1)/k} = (2400 \text{ R}) \left(\frac{1}{11} \right)^{0.4/1.4} = 1210 \text{ R}$$

The regenerator is ideal (i.e., the effectiveness is 100%) and thus,

$$T_3 = T_5 = 1210 \text{ R}$$

$$T_6 = T_2 = 1111 \text{ R}$$

The thermal efficiency of the cycle is then

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{T_6 - T_1}{T_4 - T_3} = 1 - \frac{1111 - 560}{2400 - 1210} = 0.537 = \mathbf{53.7\%}$$

The solution without a regenerator is as follows:

$$T_2 = T_1 r_p^{(k-1)/k} = (560 \text{ R})(11)^{0.4/1.4} = 1111 \text{ R}$$

$$T_4 = T_3 \left(\frac{1}{r_p} \right)^{(k-1)/k} = (2400 \text{ R}) \left(\frac{1}{11} \right)^{0.4/1.4} = 1210 \text{ R}$$

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{T_4 - T_1}{T_3 - T_2} = 1 - \frac{1210 - 560}{2400 - 1111} = 0.496 = \mathbf{49.6\%}$$

9-103E A car is powered by a gas turbine with a pressure ratio of 4. The thermal efficiency of the car and the mass flow rate of air for a net power output of 130 hp are to be determined.

Assumptions 1 Steady operating conditions exist. **2** Air is an ideal gas with variable specific heats. **3** The ambient air is 540 R and 14.5 psia. **4** The effectiveness of the regenerator is 0.9, and the isentropic efficiencies for both the compressor and the turbine are 80%. **5** The combustion gases can be treated as air.

Properties The properties of air at the compressor and turbine inlet temperatures can be obtained from Table A-17E.

Analysis The gas turbine cycle with regeneration can be analyzed as follows:

$$T_1 = 510 \text{ R} \longrightarrow \begin{matrix} h_1 = 121.88 \text{ Btu/lbm} \\ P_{r_1} = 1.1369 \end{matrix}$$

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = (4)(1.1369) = 4.548 \longrightarrow h_{2s} = 181.39 \text{ Btu/lbm}$$

$$T_3 = 2160 \text{ R} \longrightarrow \begin{matrix} h_3 = 549.35 \text{ Btu/lbm} \\ P_{r_3} = 230.12 \end{matrix}$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \left(\frac{1}{4}\right)(230.12) = 57.53 \longrightarrow h_{4s} = 372.2 \text{ Btu/lbm}$$

and

$$\eta_{\text{comp}} = \frac{h_{2s} - h_1}{h_2 - h_1} \rightarrow 0.80 = \frac{181.39 - 121.88}{h_2 - 121.88} \rightarrow h_2 = 196.27 \text{ Btu/lbm}$$

$$\eta_{\text{turb}} = \frac{h_3 - h_4}{h_3 - h_{4s}} \rightarrow 0.80 = \frac{549.35 - h_4}{549.35 - 372.2} \rightarrow h_4 = 407.63 \text{ Btu/lbm}$$

Then the thermal efficiency of the gas turbine cycle becomes

$$q_{\text{regen}} = \varepsilon(h_4 - h_2) = 0.9(407.63 - 196.27) = 190.2 \text{ Btu/lbm}$$

$$q_{\text{in}} = (h_3 - h_2) - q_{\text{regen}} = (549.35 - 196.27) - 190.2 = 162.9 \text{ Btu/lbm}$$

$$w_{\text{net,out}} = w_{\text{T,out}} - w_{\text{C,in}} = (h_3 - h_4) - (h_2 - h_1) = (549.35 - 407.63) - (196.27 - 121.88) = 67.33 \text{ Btu/lbm}$$

$$\eta_{\text{th}} = \frac{w_{\text{net,out}}}{q_{\text{in}}} = \frac{67.33 \text{ Btu/lbm}}{162.9 \text{ Btu/lbm}} = 0.413 = \mathbf{41.3\%}$$

Finally, the mass flow rate of air through the turbine becomes

$$\dot{m}_{\text{air}} = \frac{\dot{W}_{\text{net}}}{w_{\text{net,out}}} = \frac{130 \text{ hp}}{67.33 \text{ Btu/lbm}} \left(\frac{0.7068 \text{ Btu/s}}{1 \text{ hp}} \right) = \mathbf{1.36 \text{ lbm/s}}$$

9-104 An ideal Brayton cycle with regeneration is considered. The effectiveness of the regenerator is 100%. The net work output and the thermal efficiency of the cycle are to be determined.

Assumptions 1 The air standard assumptions are applicable. **2** Air is an ideal gas with variable specific heats. **3** Kinetic and potential energy changes are negligible.

Properties The properties of air are given in Table A-17.

Analysis Noting that this is an ideal cycle and thus the compression and expansion processes are isentropic, we have

$$T_1 = 300 \text{ K} \longrightarrow \begin{aligned} h_1 &= 300.19 \text{ kJ/kg} \\ P_{r_1} &= 1.386 \end{aligned}$$

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = (10)(1.386) = 13.86 \longrightarrow h_2 = 579.87 \text{ kJ/kg}$$

$$T_3 = 1200 \text{ K} \longrightarrow \begin{aligned} h_3 &= 1277.79 \text{ kJ/kg} \\ P_{r_3} &= 238 \end{aligned}$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \left(\frac{1}{10}\right)(238) = 23.8 \longrightarrow h_4 = 675.85 \text{ kJ/kg}$$

$$w_{C,\text{in}} = h_2 - h_1 = 579.87 - 300.19 = 279.68 \text{ kJ/kg}$$

$$w_{T,\text{out}} = h_3 - h_4 = 1277.79 - 675.85 = 601.94 \text{ kJ/kg}$$

Thus,

$$w_{\text{net}} = w_{T,\text{out}} - w_{C,\text{in}} = 601.94 - 279.68 = \mathbf{322.26 \text{ kJ/kg}}$$

Also, $\varepsilon = 100\% \longrightarrow h_5 = h_4 = 675.85 \text{ kJ/kg}$

$$q_{\text{in}} = h_3 - h_5 = 1277.79 - 675.85 = 601.94 \text{ kJ/kg}$$

and

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{322.26 \text{ kJ/kg}}{601.94 \text{ kJ/kg}} = \mathbf{53.5\%}$$

9-105 Problem 9-104 is reconsidered. The effects of the isentropic efficiencies for the compressor and turbine and regenerator effectiveness on net work done and the heat supplied to the cycle are to be studied. Also, the T - s diagram for the cycle is to be plotted.

Analysis Using EES, the problem is solved as follows:

9-106 An ideal Brayton cycle with regeneration is considered. The effectiveness of the regenerator is 100%. The net work output and the thermal efficiency of the cycle are to be determined.

Assumptions 1 The air standard assumptions are applicable. **2** Air is an ideal gas with constant specific heats at room temperature. **3** Kinetic and potential energy changes are negligible.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2a).

Analysis Noting that this is an ideal cycle and thus the compression and expansion processes are isentropic, we have

$$T_2 = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (300 \text{ K})(10)^{0.4/1.4} = 579.2 \text{ K}$$

$$T_4 = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = (1200 \text{ K}) \left(\frac{1}{10} \right)^{0.4/1.4} = 621.5 \text{ K}$$

$$\varepsilon = 100\% \longrightarrow T_5 = T_4 = 621.5 \text{ K and } T_6 = T_2 = 579.2 \text{ K}$$

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{c_p(T_6 - T_1)}{c_p(T_3 - T_5)} = 1 - \frac{T_6 - T_1}{T_3 - T_5} = 1 - \frac{579.2 - 300}{1200 - 621.5} = \mathbf{0.517}$$

or

$$\eta_{\text{th}} = 1 - \left(\frac{T_1}{T_3} \right) r_p^{(k-1)/k} = 1 - \left(\frac{300}{1200} \right) (10)^{(1.4-1)/1.4} = 0.517$$

Then,

$$\begin{aligned} w_{\text{net}} &= w_{\text{turb,out}} - w_{\text{comp,in}} = (h_3 - h_4) - (h_2 - h_1) \\ &= c_p [(T_3 - T_4) - (T_2 - T_1)] \\ &= (1.005 \text{ kJ/kg}\cdot\text{K}) [(1200 - 621.5) - (579.2 - 300)] \text{ K} \\ &= \mathbf{300.8 \text{ kJ/kg}} \end{aligned}$$

or

$$\begin{aligned} w_{\text{net}} &= \eta_{\text{th}} q_{\text{in}} \\ &= \eta_{\text{th}} (h_3 - h_5) \\ &= \eta_{\text{th}} c_p (T_3 - T_5) \\ &= (0.517)(1.005 \text{ kJ/kg}\cdot\text{K})(1200 - 621.5) \\ &= \mathbf{300.6 \text{ kJ/kg}} \end{aligned}$$

9-107 A Brayton cycle with regeneration using air as the working fluid is considered. The air temperature at the turbine exit, the net work output, and the thermal efficiency are to be determined.

Assumptions 1 The air standard assumptions are applicable. **2** Air is an ideal gas with variable specific heats. **3** Kinetic and potential energy changes are negligible.

Properties The properties of air are given in Table A-17.

Analysis (a) The properties of air at various states are

$$T_1 = 310 \text{ K} \longrightarrow \begin{aligned} h_1 &= 310.24 \text{ kJ/kg} \\ P_{r_1} &= 1.5546 \end{aligned}$$

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = (7)(1.5546) = 10.88 \longrightarrow h_{2s} = 541.26 \text{ kJ/kg}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} \longrightarrow h_2 = h_1 + (h_{2s} - h_1)/\eta_C = 310.24 + (541.26 - 310.24)/(0.75) = 618.26 \text{ kJ/kg}$$

$$T_3 = 1150 \text{ K} \longrightarrow \begin{aligned} h_3 &= 1219.25 \text{ kJ/kg} \\ P_{r_3} &= 200.15 \end{aligned}$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \left(\frac{1}{7}\right)(200.15) = 28.59 \longrightarrow h_{4s} = 711.80 \text{ kJ/kg}$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow h_4 = h_3 - \eta_T(h_3 - h_{4s}) = 1219.25 - (0.82)(1219.25 - 711.80) = 803.14 \text{ kJ/kg}$$

Thus,

$$T_4 = \mathbf{782.8 \text{ K}}$$

$$\begin{aligned} (b) \quad w_{\text{net}} &= w_{T,\text{out}} - w_{C,\text{in}} = (h_3 - h_4) - (h_2 - h_1) \\ &= (1219.25 - 803.14) - (618.26 - 310.24) \\ &= \mathbf{108.09 \text{ kJ/kg}} \end{aligned}$$

$$\begin{aligned} (c) \quad \varepsilon &= \frac{h_5 - h_2}{h_4 - h_2} \longrightarrow h_5 = h_2 + \varepsilon(h_4 - h_2) \\ &= 618.26 + (0.65)(803.14 - 618.26) \\ &= 738.43 \text{ kJ/kg} \end{aligned}$$

Then,

$$q_{\text{in}} = h_3 - h_5 = 1219.25 - 738.43 = 480.82 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{108.09 \text{ kJ/kg}}{480.82 \text{ kJ/kg}} = \mathbf{22.5\%}$$

9-108 A stationary gas-turbine power plant operating on an ideal regenerative Brayton cycle with air as the working fluid is considered. The power delivered by this plant is to be determined for two cases.

Assumptions 1 The air standard assumptions are applicable. **2** Air is an ideal gas. **3** Kinetic and potential energy changes are negligible.

Properties When assuming constant specific heats, the properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2a). When assuming variable specific heats, the properties of air are obtained from Table A-17.

Analysis The pressure ratio is

$$\frac{P_2}{P_1} = \frac{880 \text{ kPa}}{95 \text{ kPa}} = 9.263$$

(a) Assuming constant specific heats,

$$T_2 = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (290 \text{ K})(9.263)^{0.4/1.4} = 547.8 \text{ K}$$

$$T_4 = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = (1100 \text{ K}) \left(\frac{1}{9.263} \right)^{0.4/1.4} = 582.3 \text{ K}$$

$$\varepsilon = 100\% \longrightarrow T_5 = T_4 = 582.3 \text{ K} \text{ and } T_6 = T_2 = 547.8 \text{ K}$$

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{c_p(T_6 - T_1)}{c_p(T_3 - T_5)} = 1 - \frac{T_6 - T_1}{T_3 - T_5} = 1 - \frac{547.8 - 290}{1100 - 582.3} = 0.5020$$

$$\dot{W}_{\text{net}} = \eta_T \dot{Q}_{\text{in}} = (0.5020)(30,000 \text{ kW}) = \mathbf{15,060 \text{ kW}}$$

(b) Assuming variable specific heats,

$$T_1 = 290 \text{ K} \longrightarrow \begin{aligned} h_1 &= 290.16 \text{ kJ/kg} \\ P_{r_1} &= 1.2311 \end{aligned}$$

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = (9.263)(1.2311) = 11.40 \longrightarrow h_2 = 548.85 \text{ kJ/kg}$$

$$T_3 = 1100 \text{ K} \longrightarrow \begin{aligned} h_3 &= 1161.07 \text{ kJ/kg} \\ P_{r_3} &= 167.1 \end{aligned}$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \left(\frac{1}{9.263} \right) (167.1) = 18.04 \longrightarrow h_4 = 624.89 \text{ kJ/kg}$$

$$\varepsilon = 100\% \longrightarrow h_5 = h_4 = 624.89 \text{ kJ/kg} \text{ and } h_6 = h_2 = 548.85 \text{ kJ/kg}$$

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{h_6 - h_1}{h_3 - h_5} = 1 - \frac{548.85 - 290.16}{1161.07 - 624.89} = 0.5175$$

$$\dot{W}_{\text{net}} = \eta_T \dot{Q}_{\text{in}} = (0.5175)(30,000 \text{ kW}) = \mathbf{15,525 \text{ kW}}$$

9-109 A regenerative gas-turbine engine using air as the working fluid is considered. The amount of heat transfer in the regenerator and the thermal efficiency are to be determined.

Assumptions 1 The air standard assumptions are applicable. **2** Air is an ideal gas with variable specific heats. **3** Kinetic and potential energy changes are negligible.

Properties The properties of air are given in Table A-17.

Analysis (a) The properties at various states are

$$r_p = P_2 / P_1 = 900 / 100 = 9$$

$$T_1 = 310 \text{ K} \longrightarrow h_1 = 310.24 \text{ kJ/kg}$$

$$T_2 = 650 \text{ K} \longrightarrow h_2 = 659.84 \text{ kJ/kg}$$

$$T_3 = 1400 \text{ K} \longrightarrow h_3 = 1515.42 \text{ kJ/kg}$$

$$P_{r_3} = 450.5$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \left(\frac{1}{9}\right)(450.5) = 50.06 \longrightarrow h_{4s} = 832.44 \text{ kJ/kg}$$

$$\begin{aligned} \eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} &\longrightarrow h_4 = h_3 - \eta_T (h_3 - h_{4s}) \\ &= 1515.42 - (0.90)(1515.42 - 832.44) \\ &= 900.74 \text{ kJ/kg} \end{aligned}$$

$$q_{\text{regen}} = \varepsilon(h_4 - h_2) = (0.80)(900.74 - 659.84) = \mathbf{192.7 \text{ kJ/kg}}$$

$$\begin{aligned} (b) \quad w_{\text{net}} = w_{T,\text{out}} - w_{C,\text{in}} &= (h_3 - h_4) - (h_2 - h_1) \\ &= (1515.42 - 900.74) - (659.84 - 310.24) = 265.08 \text{ kJ/kg} \end{aligned}$$

$$q_{\text{in}} = (h_3 - h_2) - q_{\text{regen}} = (1515.42 - 659.84) - 192.7 = 662.88 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{265.08 \text{ kJ/kg}}{662.88 \text{ kJ/kg}} = 0.400 = \mathbf{40.0\%}$$

9-110 A regenerative gas-turbine engine using air as the working fluid is considered. The amount of heat transfer in the regenerator and the thermal efficiency are to be determined.

Assumptions 1 The air standard assumptions are applicable. **2** Air is an ideal gas with constant specific heats. **3** Kinetic and potential energy changes are negligible.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2a).

Analysis (a) Using the isentropic relations and turbine efficiency,

$$r_p = P_2 / P_1 = 900 / 100 = 9$$

$$T_{4s} = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = (1400 \text{ K}) \left(\frac{1}{9} \right)^{0.4/1.4} = 747.3 \text{ K}$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} = \frac{c_p(T_3 - T_4)}{c_p(T_3 - T_{4s})} \longrightarrow T_4 = T_3 - \eta_T(T_3 - T_{4s})$$

$$= 1400 - (0.90)(1400 - 747.3)$$

$$= 812.6 \text{ K}$$

$$q_{\text{regen}} = \varepsilon(h_4 - h_2) = \varepsilon c_p(T_4 - T_2) = (0.80)(1.005 \text{ kJ/kg}\cdot\text{K})(812.6 - 650)\text{K} = \mathbf{130.7 \text{ kJ/kg}}$$

$$(b) \quad w_{\text{net}} = w_{T,\text{out}} - w_{C,\text{in}} = c_p(T_3 - T_4) - c_p(T_2 - T_1)$$

$$= (1.005 \text{ kJ/kg}\cdot\text{K})[(1400 - 812.6) - (650 - 310)]\text{K} = 248.7 \text{ kJ/kg}$$

$$q_{\text{in}} = (h_3 - h_2) - q_{\text{regen}} = c_p(T_3 - T_2) - q_{\text{regen}}$$

$$= (1.005 \text{ kJ/kg}\cdot\text{K})(1400 - 650)\text{K} - 130.7 = 623.1 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{248.7 \text{ kJ/kg}}{623.1 \text{ kJ/kg}} = 0.399 = \mathbf{39.9\%}$$

9-111 A regenerative gas-turbine engine using air as the working fluid is considered. The amount of heat transfer in the regenerator and the thermal efficiency are to be determined.

Assumptions 1 The air standard assumptions are applicable. **2** Air is an ideal gas with variable specific heats. **3** Kinetic and potential energy changes are negligible.

Properties The properties of air are given in Table A-17.

Analysis (a) The properties at various states are

$$r_p = P_2 / P_1 = 900 / 100 = 9$$

$$T_1 = 310 \text{ K} \longrightarrow h_1 = 310.24 \text{ kJ/kg}$$

$$T_2 = 650 \text{ K} \longrightarrow h_2 = 659.84 \text{ kJ/kg}$$

$$T_3 = 1400 \text{ K} \longrightarrow h_3 = 1515.42 \text{ kJ/kg}$$

$$P_{r_3} = 450.5$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \left(\frac{1}{9}\right)(450.5) = 50.06 \longrightarrow h_{4s} = 832.44 \text{ kJ/kg}$$

$$\begin{aligned} \eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} &\longrightarrow h_4 = h_3 - \eta_T (h_3 - h_{4s}) \\ &= 1515.42 - (0.90)(1515.42 - 832.44) \\ &= 900.74 \text{ kJ/kg} \end{aligned}$$

$$q_{\text{regen}} = \varepsilon(h_4 - h_2) = (0.70)(900.74 - 659.84) = \mathbf{168.6 \text{ kJ/kg}}$$

$$\begin{aligned} (b) \quad w_{\text{net}} = w_{T,\text{out}} - w_{C,\text{in}} &= (h_3 - h_4) - (h_2 - h_1) \\ &= (1515.42 - 900.74) - (659.84 - 310.24) = 265.08 \text{ kJ/kg} \end{aligned}$$

$$q_{\text{in}} = (h_3 - h_2) - q_{\text{regen}} = (1515.42 - 659.84) - 168.6 = 687.18 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{265.08 \text{ kJ/kg}}{687.18 \text{ kJ/kg}} = 0.386 = \mathbf{38.6\%}$$

9-112 An expression for the thermal efficiency of an ideal Brayton cycle with an ideal regenerator is to be developed.

Assumptions 1 The air standard assumptions are applicable. **2** Air is an ideal gas with constant specific heats at room temperature. **3** Kinetic and potential energy changes are negligible.

Analysis The expressions for the isentropic compression and expansion processes are

$$T_2 = T_1 r_p^{(k-1)/k}$$

$$T_4 = T_3 \left(\frac{1}{r_p} \right)^{(k-1)/k}$$

For an ideal regenerator,

$$T_5 = T_4$$

$$T_6 = T_2$$

The thermal efficiency of the cycle is

$$\begin{aligned} \eta_{\text{th}} &= 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{T_6 - T_1}{T_3 - T_5} = 1 - \frac{T_1 (T_6 / T_1) - 1}{T_3 (1 - (T_5 / T_3))} \\ &= 1 - \frac{T_1 (T_2 / T_1) - 1}{T_3 (1 - (T_4 / T_3))} \\ &= 1 - \frac{T_1 r_p^{(k-1)/k} - 1}{T_3 (1 - r_p^{-(k-1)/k})} \\ &= 1 - \frac{T_1}{T_3} r_p^{(k-1)/k} \end{aligned}$$

Brayton Cycle with Intercooling, Reheating, and Regeneration

9-113C Because the steady-flow work is proportional to the specific volume of the gas. Intercooling decreases the average specific volume of the gas during compression, and thus the compressor work. Reheating increases the average specific volume of the gas, and thus the turbine work output.

9-114C (a) decrease, (b) decrease, and (c) decrease.

9-115C (a) increase, (b) decrease, and (c) decrease.

9-116C (a) increase, (b) decrease, (c) decrease, and (d) increase.

9-117C (a) increase, (b) decrease, (c) increase, and (d) decrease.

9-118C (c) The Carnot (or Ericsson) cycle efficiency.

9-119 A regenerative gas-turbine cycle with two stages of compression and two stages of expansion is considered. The minimum mass flow rate of air needed to develop a specified net power output is to be determined.

Assumptions 1 The air standard assumptions are applicable. **2** Air is an ideal gas with variable specific heats. **3** Kinetic and potential energy changes are negligible.

Properties The properties of air are given in Table A-17.

Analysis The mass flow rate will be a minimum when the cycle is ideal. That is, the turbine and the compressors are isentropic, the regenerator has an effectiveness of 100%, and the compression ratios across each compression or expansion stage are identical. In our case it is $r_p = \sqrt{9} = 3$. Then the work inputs to each stage of compressor are identical, so are the work outputs of each stage of the turbine.

$$T_1 = 300 \text{ K} \longrightarrow h_1 = 300.19 \text{ kJ/kg}, \quad P_{r_1} = 1.386$$

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = (3)(1.386) = 4.158 \longrightarrow h_2 = h_4 = 411.26 \text{ kJ/kg}$$

$$T_5 = 1200 \text{ K} \longrightarrow h_5 = h_7 = 1277.79 \text{ kJ/kg}, \quad P_{r_5} = 238$$

$$P_{r_6} = \frac{P_6}{P_5} P_{r_5} = \left(\frac{1}{3}\right)(238) = 79.33 \longrightarrow h_6 = h_8 = 946.36 \text{ kJ/kg}$$

$$w_{C,\text{in}} = 2(h_2 - h_1) = 2(411.26 - 300.19) = 222.14 \text{ kJ/kg}$$

$$w_{T,\text{out}} = 2(h_5 - h_6) = 2(1277.79 - 946.36) = 662.86 \text{ kJ/kg}$$

$$w_{\text{net}} = w_{T,\text{out}} - w_{C,\text{in}} = 662.86 - 222.14 = 440.72 \text{ kJ/kg}$$

$$\dot{m} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{110,000 \text{ kJ/s}}{440.72 \text{ kJ/kg}} = \mathbf{249.6 \text{ kg/s}}$$

9-120 A regenerative gas-turbine cycle with two stages of compression and two stages of expansion is considered. The minimum mass flow rate of air needed to develop a specified net power output is to be determined.

Assumptions 1 Argon is an ideal gas with constant specific heats. **2** Kinetic and potential energy changes are negligible.

Properties The properties of argon at room temperature are $c_p = 0.5203 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.667$ (Table A-2a).

Analysis The mass flow rate will be a minimum when the cycle is ideal. That is, the turbine and the compressors are isentropic, the regenerator has an effectiveness of 100%, and the compression ratios across each compression or expansion stage are identical. In our case it is $r_p = \sqrt{9} = 3$. Then the work inputs to each stage of compressor are identical, so are the work outputs of each stage of the turbine.

$$T_2 = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (300 \text{ K})(3)^{0.667/1.667} = 465.6 \text{ K}$$

$$T_6 = T_5 \left(\frac{P_6}{P_5} \right)^{(k-1)/k} = (1200 \text{ K}) \left(\frac{1}{3} \right)^{0.667/1.667} = 773.2 \text{ K}$$

$$w_{C,\text{in}} = 2(h_2 - h_1) = 2c_p(T_2 - T_1) = 2(0.5203 \text{ kJ/kg}\cdot\text{K})(465.6 - 300)\text{K} = 172.3 \text{ kJ/kg}$$

$$w_{T,\text{out}} = 2(h_5 - h_6) = 2c_p(T_5 - T_6) = 2(0.5203 \text{ kJ/kg}\cdot\text{K})(1200 - 773.2)\text{K} = 444.1 \text{ kJ/kg}$$

$$w_{\text{net}} = w_{T,\text{out}} - w_{C,\text{in}} = 444.1 - 172.3 = 271.8 \text{ kJ/kg}$$

$$\dot{m} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{110,000 \text{ kJ/s}}{271.8 \text{ kJ/kg}} = \mathbf{404.7 \text{ kg/s}}$$

9-121 An ideal gas-turbine cycle with two stages of compression and two stages of expansion is considered. The back work ratio and the thermal efficiency of the cycle are to be determined for the cases of with and without a regenerator.

Assumptions 1 The air standard assumptions are applicable. **2** Air is an ideal gas with variable specific heats. **3** Kinetic and potential energy changes are negligible.

Properties The properties of air are given in Table A-17.

Analysis (a) The work inputs to each stage of compressor are identical, so are the work outputs of each stage of the turbine since this is an ideal cycle. Then,

$$T_1 = 300 \text{ K} \longrightarrow \begin{matrix} h_1 = 300.19 \text{ kJ/kg} \\ P_{r_1} = 1.386 \end{matrix}$$

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = (3)(1.386) = 4.158 \longrightarrow h_2 = h_4 = 411.26 \text{ kJ/kg}$$

$$T_5 = 1200 \text{ K} \longrightarrow \begin{matrix} h_5 = h_7 = 1277.79 \text{ kJ/kg} \\ P_{r_5} = 238 \end{matrix}$$

$$P_{r_6} = \frac{P_6}{P_5} P_{r_5} = \left(\frac{1}{3}\right)(238) = 79.33 \longrightarrow h_6 = h_8 = 946.36 \text{ kJ/kg}$$

$$w_{C,\text{in}} = 2(h_2 - h_1) = 2(411.26 - 300.19) = 222.14 \text{ kJ/kg}$$

$$w_{T,\text{out}} = 2(h_5 - h_6) = 2(1277.79 - 946.36) = 662.86 \text{ kJ/kg}$$

Thus,

$$r_{\text{bw}} = \frac{w_{C,\text{in}}}{w_{T,\text{out}}} = \frac{222.14 \text{ kJ/kg}}{662.86 \text{ kJ/kg}} = \mathbf{33.5\%}$$

$$q_{\text{in}} = (h_5 - h_4) + (h_7 - h_6) = (1277.79 - 411.26) + (1277.79 - 946.36) = 1197.96 \text{ kJ/kg}$$

$$w_{\text{net}} = w_{T,\text{out}} - w_{C,\text{in}} = 662.86 - 222.14 = 440.72 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{440.72 \text{ kJ/kg}}{1197.96 \text{ kJ/kg}} = \mathbf{36.8\%}$$

(b) When a regenerator is used, r_{bw} remains the same. The thermal efficiency in this case becomes

$$q_{\text{regen}} = \varepsilon(h_8 - h_4) = (0.75)(946.36 - 411.26) = 401.33 \text{ kJ/kg}$$

$$q_{\text{in}} = q_{\text{in,old}} - q_{\text{regen}} = 1197.96 - 401.33 = 796.63 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{440.72 \text{ kJ/kg}}{796.63 \text{ kJ/kg}} = \mathbf{55.3\%}$$

9-122 A gas-turbine cycle with two stages of compression and two stages of expansion is considered. The back work ratio and the thermal efficiency of the cycle are to be determined for the cases of with and without a regenerator.

Assumptions 1 The air standard assumptions are applicable. **2** Air is an ideal gas with variable specific heats. **3** Kinetic and potential energy changes are negligible.

Properties The properties of air are given in Table A-17.

Analysis (a) The work inputs to each stage of compressor are identical, so are the work outputs of each stage of the turbine. Then,

$$T_1 = 300 \text{ K} \longrightarrow h_1 = 300.19 \text{ kJ/kg}$$

$$P_{r_1} = 1.386$$

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = (3)(1.386) = 4.158 \longrightarrow h_{2s} = h_{4s} = 411.26 \text{ kJ/kg}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} \longrightarrow h_2 = h_4 = h_1 + (h_{2s} - h_1) / \eta_C$$

$$= 300.19 + (411.26 - 300.19) / (0.86)$$

$$= 429.34 \text{ kJ/kg}$$

$$T_5 = 1200 \text{ K} \longrightarrow h_5 = h_7 = 1277.79 \text{ kJ/kg}$$

$$P_{r_5} = 238$$

$$P_{r_6} = \frac{P_6}{P_5} P_{r_5} = \left(\frac{1}{3}\right)(238) = 79.33 \longrightarrow h_{6s} = h_{8s} = 946.36 \text{ kJ/kg}$$

$$\eta_T = \frac{h_5 - h_6}{h_5 - h_{6s}} \longrightarrow h_6 = h_8 = h_5 - \eta_T (h_5 - h_{6s})$$

$$= 1277.79 - (0.90)(1277.79 - 946.36)$$

$$= 979.50 \text{ kJ/kg}$$

$$w_{C,\text{in}} = 2(h_2 - h_1) = 2(429.34 - 300.19) = 258.3 \text{ kJ/kg}$$

$$w_{T,\text{out}} = 2(h_5 - h_6) = 2(1277.79 - 979.50) = 596.6 \text{ kJ/kg}$$

Thus,

$$r_{\text{bw}} = \frac{w_{C,\text{in}}}{w_{T,\text{out}}} = \frac{258.3 \text{ kJ/kg}}{596.6 \text{ kJ/kg}} = 0.433 = \mathbf{43.3\%}$$

$$q_{\text{in}} = (h_5 - h_4) + (h_7 - h_6) = (1277.79 - 429.34) + (1277.79 - 979.50) = 1146.7 \text{ kJ/kg}$$

$$w_{\text{net}} = w_{T,\text{out}} - w_{C,\text{in}} = 596.6 - 258.3 = 338.3 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{338.3 \text{ kJ/kg}}{1146.7 \text{ kJ/kg}} = 0.295 = \mathbf{29.5\%}$$

(b) When a regenerator is used, r_{bw} remains the same. The thermal efficiency in this case becomes

$$q_{\text{regen}} = \varepsilon(h_8 - h_4) = (0.75)(979.50 - 429.34) = 412.6 \text{ kJ/kg}$$

$$q_{\text{in}} = q_{\text{in,old}} - q_{\text{regen}} = 1146.7 - 412.6 = 734.1 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{338.3 \text{ kJ/kg}}{734.1 \text{ kJ/kg}} = 0.461 = \mathbf{46.1\%}$$

9-123 A regenerative gas-turbine cycle with two stages of compression and two stages of expansion is considered. The thermal efficiency of the cycle is to be determined.

Assumptions 1 The air standard assumptions are applicable. **2** Air is an ideal gas with constant specific heats at room temperature. **3** Kinetic and potential energy changes are negligible.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2a).

Analysis The temperatures at various states are obtained as follows

$$T_2 = T_4 = T_1 r_p^{(k-1)/k} = (290 \text{ K})(4)^{0.4/1.4} = 430.9 \text{ K}$$

$$T_5 = T_4 + 20 = 430.9 + 20 = 450.9 \text{ K}$$

$$q_{\text{in}} = c_p (T_6 - T_5)$$

$$T_6 = T_5 + \frac{q_{\text{in}}}{c_p} = 450.9 \text{ K} + \frac{300 \text{ kJ/kg}}{1.005 \text{ kJ/kg}\cdot\text{K}} = 749.4 \text{ K}$$

$$T_7 = T_6 \left(\frac{1}{r_p} \right)^{(k-1)/k} = (749.4 \text{ K}) \left(\frac{1}{4} \right)^{0.4/1.4} = 504.3 \text{ K}$$

$$T_8 = T_7 + \frac{q_{\text{in}}}{c_p} = 504.3 \text{ K} + \frac{300 \text{ kJ/kg}}{1.005 \text{ kJ/kg}\cdot\text{K}} = 802.8 \text{ K}$$

$$T_9 = T_8 \left(\frac{1}{r_p} \right)^{(k-1)/k} = (802.8 \text{ K}) \left(\frac{1}{4} \right)^{0.4/1.4} = 540.2 \text{ K}$$

$$T_{10} = T_9 - 20 = 540.2 - 20 = 520.2 \text{ K}$$

The heat input is

$$q_{\text{in}} = 300 + 300 = 600 \text{ kJ/kg}$$

The heat rejected is

$$\begin{aligned} q_{\text{out}} &= c_p (T_{10} - T_1) + c_p (T_2 - T_3) \\ &= (1.005 \text{ kJ/kg}\cdot\text{K})(520.2 - 290 + 430.9 - 290) \text{ R} \\ &= 373.0 \text{ kJ/kg} \end{aligned}$$

The thermal efficiency of the cycle is then

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{373.0}{600} = \mathbf{0.378}$$

9-124 A regenerative gas-turbine cycle with three stages of compression and three stages of expansion is considered. The thermal efficiency of the cycle is to be determined.

Assumptions 1 The air standard assumptions are applicable. **2** Air is an ideal gas with constant specific heats at room temperature. **3** Kinetic and potential energy changes are negligible.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2a).

Analysis The temperatures at various states are obtained as follows

$$T_2 = T_4 = T_6 = T_1 r_p^{(k-1)/k} = (290 \text{ K})(4)^{0.4/1.4} = 430.9 \text{ K}$$

$$T_7 = T_6 + 20 = 430.9 + 20 = 450.9 \text{ K}$$

$$q_{\text{in}} = c_p (T_8 - T_7)$$

$$T_8 = T_7 + \frac{q_{\text{in}}}{c_p} = 450.9 \text{ K} + \frac{300 \text{ kJ/kg}}{1.005 \text{ kJ/kg}\cdot\text{K}} = 749.4 \text{ K}$$

$$T_9 = T_8 \left(\frac{1}{r_p} \right)^{(k-1)/k} = (749.4 \text{ K}) \left(\frac{1}{4} \right)^{0.4/1.4} = 504.3 \text{ K}$$

$$T_{10} = T_9 + \frac{q_{\text{in}}}{c_p} = 504.3 \text{ K} + \frac{300 \text{ kJ/kg}}{1.005 \text{ kJ/kg}\cdot\text{K}} = 802.8 \text{ K}$$

$$T_{11} = T_{10} \left(\frac{1}{r_p} \right)^{(k-1)/k} = (802.8 \text{ K}) \left(\frac{1}{4} \right)^{0.4/1.4} = 540.2 \text{ K}$$

$$T_{12} = T_{11} + \frac{q_{\text{in}}}{c_p} = 540.2 \text{ K} + \frac{300 \text{ kJ/kg}}{1.005 \text{ kJ/kg}\cdot\text{K}} = 838.7 \text{ K}$$

$$T_{13} = T_{12} \left(\frac{1}{r_p} \right)^{(k-1)/k} = (838.7 \text{ K}) \left(\frac{1}{4} \right)^{0.4/1.4} = 564.4 \text{ K}$$

$$T_{14} = T_{13} - 20 = 564.4 - 20 = 544.4 \text{ K}$$

The heat input is

$$q_{\text{in}} = 300 + 300 + 300 = 900 \text{ kJ/kg}$$

The heat rejected is

$$\begin{aligned} q_{\text{out}} &= c_p (T_{14} - T_1) + c_p (T_2 - T_3) + c_p (T_4 - T_5) \\ &= (1.005 \text{ kJ/kg}\cdot\text{K})(544.4 - 290 + 430.9 - 290 + 430.9 - 290) \text{ R} \\ &= 538.9 \text{ kJ/kg} \end{aligned}$$

The thermal efficiency of the cycle is then

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{538.9}{900} = 0.401 = \mathbf{40.1\%}$$

9-125 A regenerative gas-turbine cycle with three stages of compression and three stages of expansion is considered. The thermal efficiency of the cycle is to be determined.

Assumptions 1 The air standard assumptions are applicable. **2** Air is an ideal gas with constant specific heats at room temperature. **3** Kinetic and potential energy changes are negligible.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2a).

Analysis Since all compressors share the same compression ratio and begin at the same temperature,

$$T_2 = T_4 = T_6 = T_1 r_p^{(k-1)/k} = (290 \text{ K})(4)^{0.4/1.4} = 430.9 \text{ K}$$

From the problem statement,

$$T_7 = T_{13} - 80$$

The relations for heat input and expansion processes are

$$q_{\text{in}} = c_p (T_8 - T_7) \longrightarrow T_8 = T_7 + \frac{q_{\text{in}}}{c_p}$$

$$T_9 = T_8 \left(\frac{1}{r_p} \right)^{(k-1)/k}$$

$$T_{10} = T_9 + \frac{q_{\text{in}}}{c_p}, \quad T_{11} = T_{10} \left(\frac{1}{r_p} \right)^{(k-1)/k}$$

$$T_{12} = T_{11} + \frac{q_{\text{in}}}{c_p}, \quad T_{13} = T_{12} \left(\frac{1}{r_p} \right)^{(k-1)/k}$$

The simultaneous solution of above equations using EES software gives the following results

$$T_7 = 499.2 \text{ K}, \quad T_8 = 797.7 \text{ K}, \quad T_9 = 536.8 \text{ K}$$

$$T_{10} = 835.3 \text{ K}, \quad T_{11} = 562.1 \text{ K}, \quad T_{12} = 860.6 \text{ K}, \quad T_{13} = 579.2 \text{ K}$$

From an energy balance on the regenerator,

$$T_7 - T_6 = T_{13} - T_{14}$$

$$(T_{13} - 80) - T_6 = T_{13} - T_{14} \longrightarrow T_{14} = T_6 + 80 = 430.9 + 80 = 510.9 \text{ K}$$

The heat input is

$$q_{\text{in}} = 300 + 300 + 300 = 900 \text{ kJ/kg}$$

The heat rejected is

$$q_{\text{out}} = c_p (T_{14} - T_1) + c_p (T_2 - T_3) + c_p (T_4 - T_5)$$

$$= (1.005 \text{ kJ/kg}\cdot\text{K})(510.9 - 290 + 430.9 - 290 + 430.9 - 290) \text{ R}$$

$$= 505.3 \text{ kJ/kg}$$

The thermal efficiency of the cycle is then

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{505.3}{900} = 0.4385 = \mathbf{43.9\%}$$

Jet-Propulsion Cycles

9-126C The power developed from the thrust of the engine is called the propulsive power. It is equal to thrust times the aircraft velocity.

9-127C The ratio of the propulsive power developed and the rate of heat input is called the propulsive efficiency. It is determined by calculating these two quantities separately, and taking their ratio.

9-128C It reduces the exit velocity, and thus the thrust.

9-129E A turbojet engine operating on an ideal cycle is flying at an altitude of 20,000 ft. The pressure at the turbine exit, the velocity of the exhaust gases, and the propulsive efficiency are to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air standard assumptions are applicable. 3 Air is an ideal gas with constant specific heats at room temperature. 4 Kinetic and potential energies are negligible, except at the diffuser inlet and the nozzle exit. 5 The turbine work output is equal to the compressor work input.

Properties The properties of air at room temperature are $c_p = 0.24 \text{ Btu/lbm}\cdot\text{R}$ and $k = 1.4$ (Table A-2Ea).

Analysis (a) For convenience, we assume the aircraft is stationary and the air is moving towards the aircraft at a velocity of $V_1 = 900 \text{ ft/s}$. Ideally, the air will leave the diffuser with a negligible velocity ($V_2 \cong 0$).

Diffuser:

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}}^{\phi_0} \text{ (steady)}$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$P_5 = P_4 \left(\frac{P_{r_5}}{P_{r_4}} \right) = (145.8 \text{ psia}) \left(\frac{142.7}{367.6} \right) = 56.6 \text{ psia}$$

(b) Nozzle:

$$P_{r_6} = P_{r_5} \left(\frac{P_6}{P_5} \right) = (142.7) \left(\frac{7 \text{ psia}}{56.6 \text{ psia}} \right) = 17.66 \longrightarrow h_6 = 266.93 \text{ Btu/lbm}$$

$$\begin{aligned}\dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \quad \phi^0 \text{ (steady)} \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ h_5 + V_5^2 / 2 &= h_6 + V_6^2 / 2 \\ 0 &= h_6 - h_5 + \frac{V_6^2 - V_5^2}{2} \phi^0\end{aligned}$$

or

$$V_6 = \sqrt{2(h_5 - h_6)} = \sqrt{(2)(478.14 - 266.93)\text{Btu/lbm} \left(\frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right)} = \mathbf{3252 \text{ ft/s}}$$

(c) The propulsive efficiency is the ratio of the propulsive work to the heat input,

$$\begin{aligned}w_p &= (V_{\text{exit}} - V_{\text{inlet}})V_{\text{aircraft}} \\ &= [(3252 - 900) \text{ ft/s}](900 \text{ ft/s}) \left(\frac{1 \text{ Btu/lbm}}{25,037 \text{ ft}^2/\text{s}^2} \right) = 84.55 \text{ Btu/lbm} \\ q_{\text{in}} &= h_4 - h_3 = 617.22 - 267.56 = 349.66 \text{ Btu/lbm} \\ \eta_p &= \frac{w_p}{q_{\text{in}}} = \frac{84.55 \text{ Btu/lbm}}{349.66 \text{ Btu/lbm}} = \mathbf{24.2\%}\end{aligned}$$

9-131 A turbofan engine operating on an ideal cycle produces 50,000 N of thrust. The air temperature at the fan outlet needed to produce this thrust is to be determined.

Assumptions 1 Steady operating conditions exist. **2** The air standard assumptions are applicable. **3** Air is an ideal gas with constant specific heats at room temperature. **4** The turbine work output is equal to the compressor work input.

Properties The properties of air at room temperature are $R = 0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$, $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2a).

Analysis The total mass flow rate is

$$\nu_1 = \frac{RT}{P} = \frac{(0.287 \text{ kPa}\cdot\text{m}^3)(253 \text{ K})}{50 \text{ kPa}} = 1.452 \text{ m}^3/\text{kg}$$

$$\dot{m} = \frac{AV_1}{\nu_1} = \frac{\pi D^2 V_1}{4 \nu_1} = \frac{\pi(2.5 \text{ m})^2}{4} \frac{200 \text{ m/s}}{1.452 \text{ m}^3/\text{kg}} = 676.1 \text{ kg/s}$$

Now,

$$\dot{m}_e = \frac{\dot{m}}{8} = \frac{676.1 \text{ kg/s}}{8} = 84.51 \text{ kg/s}$$

The mass flow rate through the fan is

$$\dot{m}_f = \dot{m} - \dot{m}_e = 676.1 - 84.51 = 591.6 \text{ kg/s}$$

In order to produce the specified thrust force, the velocity at the fan exit will be

$$F = \dot{m}_f (V_{\text{exit}} - V_{\text{inlet}})$$

$$V_{\text{exit}} = V_{\text{inlet}} + \frac{F}{\dot{m}_f} = (200 \text{ m/s}) + \frac{50,000 \text{ N}}{591.6 \text{ kg/s}} \left(\frac{1 \text{ kg}\cdot\text{m/s}^2}{1 \text{ N}} \right) = 284.5 \text{ m/s}$$

An energy balance on the stream passing through the fan gives

$$c_p (T_4 - T_5) = \frac{V_{\text{exit}}^2 - V_{\text{inlet}}^2}{2}$$

$$T_5 = T_4 - \frac{V_{\text{exit}}^2 - V_{\text{inlet}}^2}{2c_p}$$

$$= 253 \text{ K} - \frac{(284.5 \text{ m/s})^2 - (200 \text{ m/s})^2}{2(1.005 \text{ kJ/kg}\cdot\text{K})} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right)$$

$$= \mathbf{232.6 \text{ K}}$$

9-132 A pure jet engine operating on an ideal cycle is considered. The velocity at the nozzle exit and the thrust produced are to be determined.

Assumptions 1 Steady operating conditions exist. **2** The air standard assumptions are applicable. **3** Air is an ideal gas with constant specific heats at room temperature. **4** The turbine work output is equal to the compressor work input.

Properties The properties of air at room temperature are $R = 0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$, $c_p = 1.005 \text{ kJ}/\text{kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2a).

Analysis (a) We assume the aircraft is stationary and the air is moving towards the aircraft at a velocity of $V_1 = 240 \text{ m/s}$. Ideally, the air will leave the diffuser with a negligible velocity ($V_2 \cong 0$).

Diffuser:

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \overset{\neq 0 \text{ (steady)}}{\longrightarrow} \dot{E}_{\text{in}} = \dot{E}_{\text{out}} \\ h_1 + V_1^2 / 2 &= h_2 + V_2^2 / 2 \longrightarrow 0 = h_2 - h_1 + \frac{V_2^2 \overset{\neq 0}{-} V_1^2}{2} \\ 0 &= c_p (T_2 - T_1) - V_1^2 / 2 \\ T_2 &= T_1 + \frac{V_1^2}{2c_p} = 260 \text{ K} + \frac{(240 \text{ m/s})^2}{(2)(1.005 \text{ kJ}/\text{kg}\cdot\text{K})} \left(\frac{1 \text{ kJ}/\text{kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 288.7 \text{ K} \\ P_2 &= P_1 \left(\frac{T_2}{T_1} \right)^{k/(k-1)} = (45 \text{ kPa}) \left(\frac{288.7 \text{ K}}{260 \text{ K}} \right)^{1.4/0.4} = 64.88 \text{ kPa} \end{aligned}$$

Compressor:

$$\begin{aligned} P_3 &= P_4 = (r_p)(P_2) = (13)(64.88 \text{ kPa}) = 843.5 \text{ kPa} \\ T_3 &= T_2 \left(\frac{P_3}{P_2} \right)^{(k-1)/k} = (288.7 \text{ K})(13)^{0.4/1.4} = 600.7 \text{ K} \end{aligned}$$

Turbine:

$$w_{\text{comp, in}} = w_{\text{turb, out}} \longrightarrow h_3 - h_2 = h_4 - h_5 \longrightarrow c_p (T_3 - T_2) = c_p (T_4 - T_5)$$

$$\text{or } T_5 = T_4 - T_3 + T_2 = 830 - 600.7 + 288.7 = 518.0 \text{ K}$$

Nozzle:

$$T_6 = T_4 \left(\frac{P_6}{P_4} \right)^{(k-1)/k} = (830 \text{ K}) \left(\frac{45 \text{ kPa}}{843.5 \text{ kPa}} \right)^{0.4/1.4} = 359.3 \text{ K}$$

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \overset{\neq 0 \text{ (steady)}}{\longrightarrow} \dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$h_5 + V_5^2 / 2 = h_6 + V_6^2 / 2$$

$$0 = h_6 - h_5 + \frac{V_6^2 - V_5^2 \overset{\neq 0}{-}}{2} \longrightarrow 0 = c_p (T_6 - T_5) + V_6^2 / 2$$

$$\text{or } V_6 = V_{\text{exit}} = \sqrt{(2)(1.005 \text{ kJ}/\text{kg}\cdot\text{K})(518.0 - 359.3)\text{K} \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ}/\text{kg}} \right)} = \mathbf{564.8 \text{ m/s}}$$

The mass flow rate through the engine is

$$\begin{aligned} \nu_1 &= \frac{RT}{P} = \frac{(0.287 \text{ kPa}\cdot\text{m}^3)(260 \text{ K})}{45 \text{ kPa}} = 1.658 \text{ m}^3/\text{kg} \\ \dot{m} &= \frac{AV_1}{\nu_1} = \frac{\pi D^2 V_1}{4 \nu_1} = \frac{\pi (1.6 \text{ m})^2}{4} \frac{240 \text{ m/s}}{1.658 \text{ m}^3/\text{kg}} = 291.0 \text{ kg/s} \end{aligned}$$

The thrust force generated is then

$$F = \dot{m}(V_{\text{exit}} - V_{\text{inlet}}) = (291.0 \text{ kg/s})(564.8 - 240) \text{ m/s} \left(\frac{1 \text{ N}}{1 \text{ kg}\cdot\text{m}/\text{s}^2} \right) = \mathbf{94,520 \text{ N}}$$

9-133 A turbojet aircraft flying at an altitude of 9150 m is operating on the ideal jet propulsion cycle. The velocity of exhaust gases, the propulsive power developed, and the rate of fuel consumption are to be determined.

Assumptions 1 Steady operating conditions exist. **2** The air standard assumptions are applicable. **3** Air is an ideal gas with constant specific heats at room temperature. **4** Kinetic and potential energies are negligible, except at the diffuser inlet and the nozzle exit. **5** The turbine work output is equal to the compressor work input.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2a).

Analysis (a) We assume the aircraft is stationary and the air is moving towards the aircraft at a velocity of $V_1 = 280 \text{ m/s}$. Ideally, the air will leave the diffuser with a negligible velocity ($V_2 \cong 0$).

Diffuser:

or,

$$T_5 = T_4 - T_3 + T_2 = 1100 - 641.9 + 280.0 = 738.1 \text{ K}$$

$$\eta_T = \frac{h_4 - h_5}{h_4 - h_{5s}} = \frac{c_p(T_4 - T_5)}{c_p(T_4 - T_{5s})}$$

$$T_{5s} = T_4 - (T_4 - T_5) / \eta_T = 1100 - (1100 - 738.1) / 0.85 = 674.3 \text{ K}$$

$$P_5 = P_4 \left(\frac{T_{5s}}{T_4} \right)^{k/(k-1)} = (649.2 \text{ kPa}) \left(\frac{674.3 \text{ K}}{1100 \text{ K}} \right)^{1.4/0.4} = 117.0 \text{ kPa}$$

Nozzle:

$$T_6 = T_5 \left(\frac{P_6}{P_5} \right)^{(k-1)/k} = (738.1 \text{ K}) \left(\frac{32 \text{ kPa}}{117.0 \text{ kPa}} \right)^{0.4/1.4} = 509.6 \text{ K}$$

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \quad \phi^0 \text{ (steady)}$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$h_5 + V_5^2 / 2 = h_6 + V_6^2 / 2$$

$$0 = h_6 - h_5 + \frac{V_6^2 - V_5^2}{2} \quad \phi^0$$

$$0 = c_p (T_6 - T_5) + V_6^2 / 2$$

or,

$$V_6 = \sqrt{(2)(1.005 \text{ kJ/kg} \cdot \text{K})(738.1 - 509.6) \text{ K} \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = \mathbf{677.8 \text{ m/s}}$$

$$\begin{aligned} (b) \quad \dot{W}_p &= \dot{m}(V_{\text{exit}} - V_{\text{inlet}}) V_{\text{aircraft}} \\ &= (50 \text{ kg/s})(677.8 - 280) \text{ m/s} (280 \text{ m/s}) \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) \\ &= \mathbf{5569 \text{ kW}} \end{aligned}$$

$$(c) \quad \dot{Q}_{\text{in}} = \dot{m}(h_4 - h_3) = \dot{m} c_p (T_4 - T_3) = (50 \text{ kg/s})(1.005 \text{ kJ/kg} \cdot \text{K})(1100 - 641.9) \text{ K} = 23,020 \text{ kJ/s}$$

$$\dot{m}_{\text{fuel}} = \frac{\dot{Q}_{\text{in}}}{\text{HV}} = \frac{23,020 \text{ kJ/s}}{42,700 \text{ kJ/kg}} = \mathbf{0.5391 \text{ kg/s}}$$

9-135 A turbojet aircraft that has a pressure ratio of 9 is stationary on the ground. The force that must be applied on the brakes to hold the plane stationary is to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air standard assumptions are applicable. 3 Air is an ideal gas with variable specific heats. 4 Kinetic and potential energies are negligible, except at the nozzle exit.

Properties The properties of air are given in Table A-17.

Analysis (a) Using variable specific heats for air,

Compressor:

$$T_1 = 290 \text{ K} \longrightarrow h_1 = 290.16 \text{ kJ/kg}$$

$$P_{r_1} = 1.2311$$

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = (9)(1.2311) = 11.08 \longrightarrow h_2 = 544.07 \text{ kJ/kg}$$

$$\dot{Q}_{\text{in}} = \dot{m}_{\text{fuel}} \times \text{HV} = (0.5 \text{ kg/s})(42,700 \text{ kJ/kg}) = 21,350 \text{ kJ/s}$$

$$q_{\text{in}} = \frac{\dot{Q}_{\text{in}}}{\dot{m}} = \frac{21,350 \text{ kJ/s}}{20 \text{ kg/s}} = 1067.5 \text{ kJ/kg}$$

$$q_{\text{in}} = h_3 - h_2 \longrightarrow h_3 = h_2 + q_{\text{in}} = 544.07 + 1067.5 = 1611.6 \text{ kJ/kg} \longrightarrow P_{r_3} = 568.5$$

Turbine:

$$w_{\text{comp,in}} = w_{\text{turb,out}} \longrightarrow h_2 - h_1 = h_3 - h_4$$

or

$$h_4 = h_3 - h_2 + h_1 = 1611.6 - 544.07 + 290.16 = 1357.7 \text{ kJ/kg}$$

Nozzle:

$$P_{r_5} = P_{r_3} \left(\frac{P_5}{P_3} \right) = (568.5) \left(\frac{1}{9} \right) = 63.17 \longrightarrow h_5 = 888.56 \text{ kJ/kg}$$

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\neq 0 \text{ (steady)}}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$h_4 + V_4^2 / 2 = h_5 + V_5^2 / 2$$

$$0 = h_5 - h_4 + \frac{V_5^2 - V_4^2}{2}$$

or

$$V_5 = \sqrt{2(h_4 - h_5)} = \sqrt{(2)(1357.7 - 888.56) \text{ kJ/kg} \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 968.6 \text{ m/s}$$

$$\text{Brake force} = \text{Thrust} = \dot{m}(V_{\text{exit}} - V_{\text{inlet}}) = (20 \text{ kg/s})(968.6 - 0) \text{ m/s} \left(\frac{1 \text{ N}}{1 \text{ kg} \cdot \text{m/s}^2} \right) = \mathbf{19,370 \text{ N}}$$

9-136 Problem 9-135 is reconsidered. The effect of compressor inlet temperature on the force that must be applied to the brakes to hold the plane stationary is to be investigated.

Analysis Using EES, the problem is solved as follows:

```

9-137 Air enters a turbojet engine. The thrust produced by this turbojet engine is to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air standard assumptions are applicable. 3 Air is an ideal gas with variable specific heats. 4 Kinetic and potential energies are negligible, except at the diffuser inlet and the nozzle exit.

Properties The properties of air are given in Table A-17.

Analysis We assume the aircraft is stationary and the air is moving towards the aircraft at a velocity of $V_1 = 300$ m/s. Taking the entire engine as our control volume and writing the steady-flow energy balance yield

$$T_1 = 280 \text{ K} \quad \longrightarrow \quad h_1 = 280.13 \text{ kJ/kg}$$

$$T_2 = 700 \text{ K} \quad \longrightarrow \quad h_2 = 713.27 \text{ kJ/kg}$$

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\approx 0}{\text{(steady)}}$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\dot{Q}_{\text{in}} + \dot{m}(h_1 + V_1^2 / 2) = \dot{m}(h_2 + V_2^2 / 2)$$

$$\dot{Q}_{\text{in}} = \dot{m} \left(h_2 - h_1 + \frac{V_2^2 - V_1^2}{2} \right)$$

$$15,000 \text{ kJ/s} = (16 \text{ kg/s}) \left[713.27 - 280.13 + \frac{V_2^2 - (300 \text{ m/s})^2}{2} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) \right]$$

It gives

$$V_2 = 1048 \text{ m/s}$$

Thus,

$$F_p = \dot{m}(V_2 - V_1) = (16 \text{ kg/s})(1048 - 300) \text{ m/s} = \mathbf{11,968 \text{ N}}$$

Second-Law Analysis of Gas Power Cycles

9-138 The total exergy destruction associated with the Otto cycle described in Prob. 9-33 and the exergy at the end of the power stroke are to be determined.

Analysis From Prob. 9-33, $q_{in} = 750$, $q_{out} = 357.62$ kJ/kg, $T_1 = 300$ K, and $T_4 = 774.5$ K.

The total exergy destruction associated with this Otto cycle is determined from

$$x_{\text{destroyed}} = T_0 \left(\frac{q_{\text{out}}}{T_L} - \frac{q_{\text{in}}}{T_H} \right) = (300 \text{ K}) \left(\frac{357.62 \text{ kJ/kg}}{300 \text{ K}} - \frac{750 \text{ kJ/kg}}{2000 \text{ K}} \right) = \mathbf{245.1 \text{ kJ/kg}}$$

Noting that state 4 is identical to the state of the surroundings, the exergy at the end of the power stroke (state 4) is determined from

$$\phi_4 = (u_4 - u_0) - T_0(s_4 - s_0) + P_0(v_4 - v_0)$$

where

$$u_4 - u_0 = u_4 - u_1 = q_{\text{out}} = 357.62 \text{ kJ/kg}$$

$$v_4 - v_0 = v_4 - v_1 = 0$$

$$\begin{aligned} s_4 - s_0 &= s_4 - s_1 = s_4^\circ - s_1^\circ - R \ln \frac{P_4}{P_1} = s_4^\circ - s_1^\circ - R \ln \frac{T_4 v_1}{T_1 v_4} = s_4^\circ - s_1^\circ - R \ln \frac{T_4}{T_1} \\ &= 2.6823 - 1.70203 - (0.287 \text{ kJ/kg} \cdot \text{K}) \ln \frac{774.5 \text{ K}}{300 \text{ K}} = 0.7081 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

Thus,

$$\phi_4 = (357.62 \text{ kJ/kg}) - (300 \text{ K})(0.7081 \text{ kJ/kg} \cdot \text{K}) + 0 = \mathbf{145.2 \text{ kJ/kg}}$$

9-139 The total exergy destruction associated with the Diesel cycle described in Prob. 9-46 and the exergy at the end of the compression stroke are to be determined.

Analysis From Prob. 9-46, $q_{in} = 1019.7$, $q_{out} = 445.63$ kJ/kg, $T_1 = 300$ K, $v_1 = 0.906$ m³/kg, and $v_2 = v_1 / r = 0.906 / 12 = 0.0566$ m³/kg.

The total exergy destruction associated with this Otto cycle is determined from

$$x_{\text{destroyed}} = T_0 \left(\frac{q_{\text{out}}}{T_L} - \frac{q_{\text{in}}}{T_H} \right) = (300 \text{ K}) \left(\frac{445.63 \text{ kJ/kg}}{300 \text{ K}} - \frac{1019.7 \text{ kJ/kg}}{2000 \text{ K}} \right) = \mathbf{292.7 \text{ kJ/kg}}$$

Noting that state 1 is identical to the state of the surroundings, the exergy at the end of the compression stroke (state 2) is determined from

$$\begin{aligned} \phi_2 &= (u_2 - u_0) - T_0(s_2 - s_0) + P_0(v_2 - v_0) \\ &= (u_2 - u_1) - T_0(s_2 - s_1) + P_0(v_2 - v_1) \\ &= (643.3 - 214.07) - 0 + (95 \text{ kPa})(0.0566 - 0.906) \text{ m}^3/\text{kg} \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= \mathbf{348.6 \text{ kJ/kg}} \end{aligned}$$

9-140E The exergy destruction associated with the heat rejection process of the Diesel cycle described in Prob. 9-52E and the exergy at the end of the expansion stroke are to be determined.

Analysis From Prob. 9-52E, $q_{\text{out}} = 173.7 \text{ Btu/lbm}$, $T_1 = 580 \text{ R}$, $P_1 = 14.7 \text{ psia}$, and $\nu_4 = \nu_1$.

Also, we obtain temperature and pressure at state 4 as

$$\nu_{r_4} = 9.375 \longrightarrow T_4 = 1531.8 \text{ R}$$

$$\frac{P_4}{P_1} = \frac{T_4}{T_1} \rightarrow P_4 = P_1 \frac{T_4}{T_1} = (14.7 \text{ kPa}) \frac{1531.8 \text{ K}}{580 \text{ K}} = 38.82 \text{ kPa}$$

The entropy change during process 4-1 is

$$\begin{aligned} s_1 - s_4 &= s_1^{\circ} @ 580 \text{ R} - s_4^{\circ} @ 1531.8 \text{ R} - R \ln(P_1 / P_4) \\ &= 0.61793 - 0.85970 - (0.06855) \ln(14.7 / 38.82) \\ &= -0.1752 \text{ Btu/lbm} \cdot \text{R} \end{aligned}$$

Thus,

$$x_{\text{destroyed},41} = T_0 \left(s_1 - s_4 + \frac{q_{R,41}}{T_R} \right) = (540 \text{ R}) \left(-0.1752 \text{ Btu/lbm} \cdot \text{R} + \frac{173.7 \text{ Btu/lbm}}{540 \text{ R}} \right) = \mathbf{79.1 \text{ Btu/lbm}}$$

Noting that state 4 is identical to the state of the surroundings, the exergy at the end of the power stroke (state 4) is determined from

$$\phi_4 = (u_4 - u_0) - T_0(s_4 - s_0) + P_0(\nu_4 - \nu_0)$$

where

$$\begin{aligned} u_4 - u_0 &= u_4 - u_1 = q_{\text{out}} = 173.7 \text{ Btu/lbm} \cdot \text{R} \\ \nu_4 - \nu_0 &= \nu_4 - \nu_1 = 0 \\ s_4 - s_0 &= s_4 - s_1 = 0.1752 \text{ Btu/lbm} \cdot \text{R} \end{aligned}$$

Thus,

$$\phi_4 = (173.7 \text{ Btu/lbm}) - (540 \text{ R})(0.1752 \text{ Btu/lbm} \cdot \text{R}) + 0 = \mathbf{79.1 \text{ Btu/lbm}}$$

Discussion Note that the exergy at state 4 is identical to the exergy destruction for the process 4-1 since state 1 is identical to the dead state, and the entire exergy at state 4 is wasted during process 4-1.

9-141 The exergy loss of each process for an air-standard Stirling cycle described in Prob. 9-74 is to be determined.

Analysis From Prob. 9-74, $q_{in} = 1275 \text{ kJ/kg}$, $q_{out} = 212.5 \text{ kJ/kg}$, $T_1 = T_2 = 1788 \text{ K}$, $T_3 = T_4 = 298 \text{ K}$. The exergy destruction during a process of the cycle is

$$x_{dest} = T_0 s_{gen} = T_0 \left(\Delta s - \frac{q_{in}}{T_{source}} + \frac{q_{out}}{T_{sink}} \right)$$

Application of this equation for each process of the cycle gives

$$\begin{aligned} s_2 - s_1 &= c_v \ln \frac{T_2}{T_1} + R \ln \frac{v_2}{v_1} \\ &= 0 + (0.287 \text{ kJ/kg} \cdot \text{K}) \ln(12) = 0.7132 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

$$\begin{aligned} x_{dest,1-2} &= T_0 \left(s_2 - s_1 - \frac{q_{in}}{T_{source}} \right) \\ &= (298 \text{ K}) \left(0.7132 \text{ kJ/kg} \cdot \text{K} - \frac{1275 \text{ kJ/kg}}{1788 \text{ K}} \right) = \mathbf{0.034 \text{ kJ/kg} \approx 0} \end{aligned}$$

$$\begin{aligned} s_4 - s_3 &= c_v \ln \frac{T_4}{T_3} + R \ln \frac{v_4}{v_3} \\ &= 0 + (0.287 \text{ kJ/kg} \cdot \text{K}) \ln \left(\frac{1}{12} \right) = -0.7132 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

$$\begin{aligned} x_{dest,3-4} &= T_0 \left(s_4 - s_3 + \frac{q_{out}}{T_{sink}} \right) \\ &= (298 \text{ K}) \left(-0.7132 \text{ kJ/kg} \cdot \text{K} + \frac{212.5 \text{ kJ/kg}}{298 \text{ K}} \right) = \mathbf{-0.034 \text{ kJ/kg} \approx 0} \end{aligned}$$

These results are not surprising since Stirling cycle is totally reversible. Exergy destructions are not calculated for processes 2-3 and 4-1 because there is no interaction with the surroundings during these processes to alter the exergy destruction.

9-142 The exergy destruction associated with each of the processes of the Brayton cycle described in Prob. 9-83 is to be determined.

Analysis From Prob. 9-83, $q_{\text{in}} = 698.3 \text{ kJ/kg}$, $q_{\text{out}} = 487.9 \text{ kJ/kg}$, and

$$T_1 = 295 \text{ K} \longrightarrow s_1^\circ = 1.68515 \text{ kJ/kg} \cdot \text{K}$$

$$h_2 = 626.60 \text{ kJ/kg} \longrightarrow s_2^\circ = 2.44117 \text{ kJ/kg} \cdot \text{K}$$

$$T_3 = 1240 \text{ K} \longrightarrow s_3^\circ = 3.21751 \text{ kJ/kg} \cdot \text{K}$$

$$h_4 = 783.04 \text{ kJ/kg} \longrightarrow s_4^\circ = 2.66807 \text{ kJ/kg} \cdot \text{K}$$

Thus,

$$\begin{aligned} x_{\text{destroyed},12} &= T_0 s_{\text{gen},12} = T_0 (s_2 - s_1) = T_0 \left(s_2^\circ - s_1^\circ - R \ln \frac{P_2}{P_1} \right) = \\ &= (295 \text{ K}) (2.44117 - 1.68515 - (0.287 \text{ kJ/kg} \cdot \text{K}) \ln(10)) \\ &= \mathbf{28.08 \text{ kJ/kg}} \end{aligned}$$

$$\begin{aligned} x_{\text{destroyed},23} &= T_0 s_{\text{gen},23} = T_0 \left(s_3 - s_2 + \frac{q_{R,23}}{T_R} \right) = T_0 \left(s_3^\circ - s_2^\circ - R \ln \frac{P_3}{P_2} \overset{\phi_0}{+} \frac{-q_{\text{in}}}{T_H} \right) \\ &= (295 \text{ K}) \left(3.21751 - 2.44117 - \frac{698.3 \text{ kJ/kg}}{1600 \text{ K}} \right) \\ &= \mathbf{100.3 \text{ kJ/kg}} \end{aligned}$$

$$\begin{aligned} x_{\text{destroyed},34} &= T_0 s_{\text{gen},34} = T_0 (s_4 - s_3) = T_0 \left(s_4^\circ - s_3^\circ - R \ln \frac{P_4}{P_3} \right) = \\ &= (295 \text{ K}) (2.66807 - 3.21751 - (0.287 \text{ kJ/kg} \cdot \text{K}) \ln(1/10)) \\ &= \mathbf{32.86 \text{ kJ/kg}} \end{aligned}$$

$$\begin{aligned} x_{\text{destroyed},41} &= T_0 s_{\text{gen},41} = T_0 \left(s_1 - s_4 + \frac{q_{R,41}}{T_R} \right) = T_0 \left(s_1^\circ - s_4^\circ - R \ln \frac{P_1}{P_4} \overset{\phi_0}{+} \frac{q_{\text{out}}}{T_L} \right) \\ &= (295 \text{ K}) \left(1.68515 - 2.66807 + \frac{487.9 \text{ kJ/kg}}{295 \text{ K}} \right) \\ &= \mathbf{197.9 \text{ kJ/kg}} \end{aligned}$$

9-143 Exergy analysis is to be used to answer the question in Prob. 9-86.

Analysis From Prob. 9-86, $T_1 = 288 \text{ K}$, $T_{2s} = 585.8 \text{ K}$, $T_2 = 660.2 \text{ K}$, $T_3 = 873.0 \text{ K}$, $T_{4s} = 429.2 \text{ K}$, $T_4 = 518.0 \text{ K}$, $r_p = 12$. The exergy change of a flow stream between an inlet and exit state is given by

$$\Delta\psi = h_e - h_i - T_0(s_e - s_i)$$

This is also the expression for reversible work. Application of this equation for isentropic and actual compression processes gives

$$\begin{aligned} s_{2s} - s_1 &= c_p \ln \frac{T_{2s}}{T_1} - R \ln \frac{P_2}{P_1} \\ &= (1.005 \text{ kJ/kg} \cdot \text{K}) \ln \frac{585.8 \text{ K}}{288 \text{ K}} - (0.287 \text{ kJ/kg} \cdot \text{K}) \ln(12) \\ &= 0.0003998 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

$$\begin{aligned} w_{\text{rev},1-2s} &= c_p(T_{2s} - T_1) - T_0(s_{2s} - s_1) \\ &= (1.005 \text{ kJ/kg} \cdot \text{K})(585.8 - 288) \text{ K} - (288 \text{ K})(0.0003998 \text{ kJ/kg} \cdot \text{K}) = 299.2 \text{ kJ/kg} \end{aligned}$$

$$\begin{aligned} s_2 - s_1 &= c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \\ &= (1.005 \text{ kJ/kg} \cdot \text{K}) \ln \frac{660.2 \text{ K}}{288 \text{ K}} - (0.287 \text{ kJ/kg} \cdot \text{K}) \ln(12) = 0.1206 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

$$\begin{aligned} w_{\text{rev},1-2} &= c_p(T_2 - T_1) - T_0(s_2 - s_1) \\ &= (1.005 \text{ kJ/kg} \cdot \text{K})(660.2 - 288) \text{ K} - (288 \text{ K})(0.1206 \text{ kJ/kg} \cdot \text{K}) = 339.3 \text{ kJ/kg} \end{aligned}$$

The irreversibilities therefore increase the minimum work that must be supplied to the compressor by

$$\Delta w_{\text{rev},C} = w_{\text{rev},1-2} - w_{\text{rev},1-2s} = 339.3 - 299.2 = \mathbf{40.2 \text{ kJ/kg}}$$

Repeating the calculations for the turbine,

$$\begin{aligned} s_3 - s_{4s} &= c_p \ln \frac{T_3}{T_{4s}} - R \ln \frac{P_3}{P_4} \\ &= (1.005 \text{ kJ/kg} \cdot \text{K}) \ln \frac{873 \text{ K}}{429.2 \text{ K}} - (0.287 \text{ kJ/kg} \cdot \text{K}) \ln(12) = 0.0003944 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

$$\begin{aligned} w_{\text{rev},3-4s} &= c_p(T_3 - T_{4s}) - T_0(s_3 - s_{4s}) \\ &= (1.005 \text{ kJ/kg} \cdot \text{K})(873 - 429.2) \text{ K} - (288 \text{ K})(0.0003944 \text{ kJ/kg} \cdot \text{K}) = 445.9 \text{ kJ/kg} \end{aligned}$$

$$\begin{aligned} s_3 - s_4 &= c_p \ln \frac{T_3}{T_4} - R \ln \frac{P_3}{P_4} \\ &= (1.005 \text{ kJ/kg} \cdot \text{K}) \ln \frac{873 \text{ K}}{518.0 \text{ K}} - (0.287 \text{ kJ/kg} \cdot \text{K}) \ln(12) = -0.1885 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

$$\begin{aligned} w_{\text{rev},3-4} &= c_p(T_3 - T_4) - T_0(s_3 - s_4) \\ &= (1.005 \text{ kJ/kg} \cdot \text{K})(873 - 518.0) \text{ K} - (288 \text{ K})(-0.1885 \text{ kJ/kg} \cdot \text{K}) = 411.1 \text{ kJ/kg} \end{aligned}$$

$$\Delta w_{\text{rev},T} = w_{\text{rev},3-4s} - w_{\text{rev},3-4} = 445.9 - 411.1 = \mathbf{34.8 \text{ kJ/kg}}$$

Hence, it is clear that the compressor is a little more sensitive to the irreversibilities than the turbine.

9-144 The total exergy destruction associated with the Brayton cycle described in Prob. 9-107 and the exergy at the exhaust gases at the turbine exit are to be determined.

Properties The gas constant of air is $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ (Table A-1).

Analysis From Prob. 9-107, $q_{in} = 480.82$, $q_{out} = 372.73 \text{ kJ/kg}$, and

$$T_1 = 310 \text{ K} \longrightarrow s_1^\circ = 1.73498 \text{ kJ/kg}\cdot\text{K}$$

$$h_2 = 618.26 \text{ kJ/kg} \longrightarrow s_2^\circ = 2.42763 \text{ kJ/kg}\cdot\text{K}$$

$$T_3 = 1150 \text{ K} \longrightarrow s_3^\circ = 3.12900 \text{ kJ/kg}\cdot\text{K}$$

$$h_4 = 803.14 \text{ kJ/kg} \longrightarrow s_4^\circ = 2.69407 \text{ kJ/kg}\cdot\text{K}$$

$$h_5 = 738.43 \text{ kJ/kg} \longrightarrow s_5^\circ = 2.60815 \text{ kJ/kg}\cdot\text{K}$$

and, from an energy balance on the heat exchanger,

$$h_5 - h_2 = h_4 - h_6 \longrightarrow h_6 = 803.14 - (738.43 - 618.26) = 682.97 \text{ kJ/kg}$$

$$\longrightarrow s_6^\circ = 2.52861 \text{ kJ/kg}\cdot\text{K}$$

Thus,

$$\begin{aligned} x_{\text{destroyed},12} &= T_0 s_{\text{gen},12} = T_0 (s_2 - s_1) = T_0 \left(s_2^\circ - s_1^\circ - R \ln \frac{P_2}{P_1} \right) \\ &= (290 \text{ K}) (2.42763 - 1.73498 - (0.287 \text{ kJ/kg}\cdot\text{K}) \ln(7)) = \mathbf{38.91 \text{ kJ/kg}} \end{aligned}$$

$$\begin{aligned} x_{\text{destroyed},34} &= T_0 s_{\text{gen},34} = T_0 (s_4 - s_3) = T_0 \left(s_4^\circ - s_3^\circ - R \ln \frac{P_4}{P_3} \right) \\ &= (290 \text{ K}) (2.69407 - 3.12900 - (0.287 \text{ kJ/kg}\cdot\text{K}) \ln(1/7)) = \mathbf{35.83 \text{ kJ/kg}} \end{aligned}$$

$$\begin{aligned} x_{\text{destroyed,regen}} &= T_0 s_{\text{gen,regen}} = T_0 [(s_5 - s_2) + (s_6 - s_4)] = T_0 [(s_5^\circ - s_2^\circ) + (s_6^\circ - s_4^\circ)] \\ &= (290 \text{ K}) (2.60815 - 2.42763 + 2.52861 - 2.69407) = \mathbf{4.37 \text{ kJ/kg}} \end{aligned}$$

$$\begin{aligned} x_{\text{destroyed},53} &= T_0 s_{\text{gen},53} = T_0 \left(s_3 - s_5 - \frac{q_{R,53}}{T_R} \right) = T_0 \left(s_3^\circ - s_5^\circ - R \ln \frac{P_3}{P_5} \phi^0 - \frac{q_{in}}{T_H} \right) \\ &= (290 \text{ K}) \left(3.12900 - 2.60815 - \frac{480.82 \text{ kJ/kg}}{1500 \text{ K}} \right) = \mathbf{58.09 \text{ kJ/kg}} \end{aligned}$$

$$\begin{aligned} x_{\text{destroyed},61} &= T_0 s_{\text{gen},61} = T_0 \left(s_1 - s_6 + \frac{q_{R,61}}{T_R} \right) = T_0 \left(s_1^\circ - s_6^\circ - R \ln \frac{P_1}{P_6} \phi^0 + \frac{q_{out}}{T_L} \right) \\ &= (290 \text{ K}) \left(1.73498 - 2.52861 + \frac{372.73 \text{ kJ/kg}}{290 \text{ K}} \right) = \mathbf{142.6 \text{ kJ/kg}} \end{aligned}$$

Noting that $h_0 = h_{@ 290 \text{ K}} = 290.16 \text{ kJ/kg}$ and $T_0 = 290 \text{ K} \longrightarrow s_1^\circ = 1.66802 \text{ kJ/kg}\cdot\text{K}$, the stream exergy at the exit of the regenerator (state 6) is determined from

$$\phi_6 = (h_6 - h_0) - T_0 (s_6 - s_0) + \frac{V_6^2}{2} \phi^0 + gz_6 \phi^0$$

where

$$s_6 - s_0 = s_6 - s_1 = s_6^\circ - s_1^\circ - R \ln \frac{P_6}{P_1} \phi^0 = 2.52861 - 1.66802 = 0.86059 \text{ kJ/kg}\cdot\text{K}$$

Thus,

$$\phi_6 = 682.97 - 290.16 - (290 \text{ K})(0.86059 \text{ kJ/kg}\cdot\text{K}) = \mathbf{143.2 \text{ kJ/kg}}$$

9-145 Prob. 9-144 is reconsidered. The effect of the cycle pressure on the total irreversibility for the cycle and the exergy of the exhaust gas leaving the regenerator is to be investigated.

Analysis Using EES, the problem is solved as follows:

"Given"

```

9-146 The exergy destruction associated with each of the processes of the Brayton cycle described in Prob. 9-109 and the exergy at the end of the exhaust gases at the exit of the regenerator are to be determined.

Properties The gas constant of air is $R = 0.287 \text{ kJ/kg} \cdot \text{K}$ (Table A-1).

Analysis From Prob. 9-109, $q_{\text{in}} = 662.88 \text{ kJ/kg}$, $q_{\text{out}} = 397.80 \text{ kJ/kg}$, and

$$T_1 = 310 \text{ K} \longrightarrow s_1^\circ = 1.73498 \text{ kJ/kg} \cdot \text{K}$$

$$h_2 = 659.84 \text{ kJ/kg} \longrightarrow s_2^\circ = 2.49364 \text{ kJ/kg} \cdot \text{K}$$

$$T_3 = 1400 \text{ K} \longrightarrow s_3^\circ = 3.36200 \text{ kJ/kg} \cdot \text{K}$$

$$h_4 = 900.74 \text{ kJ/kg} \longrightarrow s_4^\circ = 2.81216 \text{ kJ/kg} \cdot \text{K}$$

$$h_5 = 852.54 \text{ kJ/kg} \longrightarrow s_5^\circ = 2.75537 \text{ kJ/kg} \cdot \text{K}$$

$$h_6 = 708.04 \text{ kJ/kg} \longrightarrow s_6^\circ = 2.56525 \text{ kJ/kg} \cdot \text{K}$$

where

$$q_{\text{out}} = q_{\text{in}} - w_{\text{net}} = 662.88 - 265.08 = 397.80 \text{ kJ/kg}$$

$$h_6 = h_1 + q_{\text{out}} = 310.24 + 397.80 = 708.04 \text{ kJ/kg}$$

$$h_5 - h_2 = h_4 - h_6 \rightarrow h_5 - 659.84 = 900.74 - 708.04 \rightarrow h_5 = 852.54$$

Thus,

$$\begin{aligned} x_{\text{destroyed},12} &= T_0 s_{\text{gen},12} = T_0 (s_2 - s_1) = T_0 \left(s_2^\circ - s_1^\circ - R \ln \frac{P_2}{P_1} \right) \\ &= (300 \text{ K}) (2.49364 - 1.73498 - (0.287 \text{ kJ/kg} \cdot \text{K}) \ln(9)) = \mathbf{38.42 \text{ kJ/kg}} \end{aligned}$$

$$\begin{aligned} x_{\text{destroyed},34} &= T_0 s_{\text{gen},34} = T_0 (s_4 - s_3) = T_0 \left(s_4^\circ - s_3^\circ - R \ln \frac{P_4}{P_3} \right) \\ &= (300 \text{ K}) (2.81216 - 3.36200 - (0.287 \text{ kJ/kg} \cdot \text{K}) \ln(1/9)) = \mathbf{24.23 \text{ kJ/kg}} \end{aligned}$$

$$\begin{aligned} x_{\text{destroyed,regen}} &= T_0 s_{\text{gen,regen}} = T_0 [(s_5 - s_2) + (s_6 - s_4)] = T_0 [(s_5^\circ - s_2^\circ) + (s_6^\circ - s_4^\circ)] \\ &= (300 \text{ K}) (2.75537 - 2.49364 + 2.56525 - 2.81216) = \mathbf{4.47 \text{ kJ/kg}} \end{aligned}$$

$$\begin{aligned} x_{\text{destroyed},53} &= T_0 s_{\text{gen},53} = T_0 \left(s_3 - s_5 - \frac{q_{R,53}}{T_R} \right) = T_0 \left(s_3^\circ - s_5^\circ - R \ln \frac{P_3}{P_5} \frac{\phi_0}{T_H} - \frac{q_{\text{in}}}{T_H} \right) \\ &= (300 \text{ K}) \left(3.36200 - 2.75537 - \frac{662.88 \text{ kJ/kg}}{1260 \text{ K}} \right) = \mathbf{24.16 \text{ kJ/kg}} \end{aligned}$$

$$\begin{aligned} x_{\text{destroyed},61} &= T_0 s_{\text{gen},61} = T_0 \left(s_1 - s_6 + \frac{q_{R,61}}{T_R} \right) = T_0 \left(s_1^\circ - s_6^\circ - R \ln \frac{P_1}{P_6} \frac{\phi_0}{T_L} + \frac{q_{\text{out}}}{T_L} \right) \\ &= (300 \text{ K}) \left(1.73498 - 2.56525 + \frac{397.80 \text{ kJ/kg}}{300 \text{ K}} \right) = \mathbf{148.7 \text{ kJ/kg}} \end{aligned}$$

Noting that at $T_0 = 300 \text{ K} \rightarrow h_0 = h_{@ 300 \text{ K}} = 300.19 \text{ kJ/kg}$ and $s_0^\circ = 1.70203 \text{ kJ/kg} \cdot \text{K}$

the stream exergy at the exit of the regenerator (state 6) is determined from

$$\phi_6 = (h_6 - h_0) - T_0 (s_6 - s_0) + \frac{V_6^2}{2} \frac{\phi_0}{T_0} + g z_6 \frac{\phi_0}{T_0}$$

$$\text{where } s_6 - s_0 = s_6^\circ - s_0^\circ - R \ln \frac{P_6}{P_1} \frac{\phi_0}{T_0} = 2.56525 - 1.70203 = 0.86322 \text{ kJ/kg} \cdot \text{K}$$

$$\text{Thus, } \phi_6 = 708.04 - 300.19 - (300 \text{ K})(0.86322 \text{ kJ/kg} \cdot \text{K}) = \mathbf{148.9 \text{ kJ/kg}}$$

9-147 The exergy loss of each process for a regenerative Brayton cycle with three stages of reheating and intercooling described in Prob. 9-125 is to be determined.

Analysis From Prob. 9-125,

$$r_p = 4, \quad q_{in,7-8} = q_{in,9-10} = q_{in,11-12} = 300 \text{ kJ/kg},$$

$$q_{out,14-1} = 222.0 \text{ kJ/kg}, \quad q_{out,2-3} = q_{out,4-5} = 141.6 \text{ kJ/kg},$$

$$T_1 = T_3 = T_5 = 290 \text{ K}, \quad T_2 = T_4 = T_6 = 430.9 \text{ K}$$

$$T_7 = 499.2 \text{ K}, \quad T_8 = 797.7 \text{ K}, \quad T_9 = 536.8 \text{ K}$$

$$T_{10} = 835.3 \text{ K}, \quad T_{11} = 562.1 \text{ K}, \quad T_{12} = 860.6 \text{ K},$$

$$T_{13} = 579.2 \text{ K}, \quad T_{14} = 510.9 \text{ K}$$

The exergy destruction during a process of a stream from an inlet state to exit state is given by

$$x_{dest} = T_0 s_{gen} = T_0 \left(s_e - s_i - \frac{q_{in}}{T_{source}} + \frac{q_{out}}{T_{sink}} \right)$$

Application of this equation for each process of the cycle gives

$$\begin{aligned} x_{dest,1-2} = x_{dest,3-4} = x_{dest,5-6} &= T_0 \left(c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \right) \\ &= (290) \left[(1.005) \ln \frac{430.9}{290} - (0.287) \ln(4) \right] = \mathbf{0.03 \text{ kJ/kg} \approx 0} \end{aligned}$$

$$x_{dest,7-8} = T_0 \left(c_p \ln \frac{T_8}{T_7} - R \ln \frac{P_8}{P_7} - \frac{q_{in,7-8}}{T_{source}} \right) = (290) \left[(1.005) \ln \frac{797.7}{499.2} - 0 - \frac{300}{860.6} \right] = \mathbf{35.5 \text{ kJ/kg}}$$

$$x_{dest,9-10} = T_0 \left(c_p \ln \frac{T_{10}}{T_9} - R \ln \frac{P_{10}}{P_9} - \frac{q_{in,9-10}}{T_{source}} \right) = (290) \left[(1.005) \ln \frac{835.3}{536.8} - 0 - \frac{300}{860.6} \right] = \mathbf{27.8 \text{ kJ/kg}}$$

$$x_{dest,11-12} = T_0 \left(c_p \ln \frac{T_{12}}{T_{11}} - R \ln \frac{P_{12}}{P_{11}} - \frac{q_{in,11-12}}{T_{source}} \right) = (290) \left[(1.005) \ln \frac{860.6}{562.1} - 0 - \frac{300}{860.6} \right] = \mathbf{23.1 \text{ kJ/kg}}$$

$$x_{dest,8-9} = T_0 \left(c_p \ln \frac{T_9}{T_8} - R \ln \frac{P_9}{P_8} \right) = (290) \left[(1.005) \ln \frac{536.8}{797.7} - (0.287) \ln \left(\frac{1}{4} \right) \right] = \mathbf{-0.06 \text{ kJ/kg} \approx 0}$$

$$x_{dest,10-11} = T_0 \left(c_p \ln \frac{T_{11}}{T_{10}} - R \ln \frac{P_{11}}{P_{10}} \right) = (290) \left[(1.005) \ln \frac{562.1}{835.3} - (0.287) \ln \left(\frac{1}{4} \right) \right] = \mathbf{-0.07 \text{ kJ/kg} \approx 0}$$

$$x_{dest,12-13} = T_0 \left(c_p \ln \frac{T_{13}}{T_{12}} - R \ln \frac{P_{13}}{P_{12}} \right) = (290) \left[(1.005) \ln \frac{579.2}{860.6} - (0.287) \ln \left(\frac{1}{4} \right) \right] = \mathbf{-0.03 \text{ kJ/kg} \approx 0}$$

$$x_{dest,14-1} = T_0 \left(c_p \ln \frac{T_1}{T_{14}} - R \ln \frac{P_1}{P_{14}} + \frac{q_{out,14-1}}{T_{sink}} \right) = (290) \left[(1.005) \ln \frac{290}{510.9} - 0 + \frac{222.0}{290} \right] = \mathbf{57.0 \text{ kJ/kg}}$$

$$x_{dest,2-3} = x_{dest,4-5} = T_0 \left(c_p \ln \frac{T_3}{T_2} - R \ln \frac{P_3}{P_2} + \frac{q_{out,2-3}}{T_{sink}} \right) = (290) \left[(1.005) \ln \frac{290}{430.9} - 0 + \frac{141.6}{290} \right] = \mathbf{26.2 \text{ kJ/kg}}$$

$$\begin{aligned} x_{dest,regen} &= T_0 (\Delta s_{6-7} + \Delta s_{13-14}) = T_0 \left(c_p \ln \frac{T_7}{T_6} + c_p \ln \frac{T_{14}}{T_{13}} \right) \\ &= (290) \left[(1.005) \ln \frac{499.2}{430.9} + (1.005) \ln \frac{510.9}{579.2} \right] = \mathbf{6.30 \text{ kJ/kg}} \end{aligned}$$

9-148 A gas-turbine plant operates on the regenerative Brayton cycle. The isentropic efficiency of the compressor, the effectiveness of the regenerator, the air-fuel ratio in the combustion chamber, the net power output, the back work ratio, the thermal efficiency, the second law efficiency, the exergy efficiencies of the compressor, the turbine, and the regenerator, and the rate of the exergy of the combustion gases at the regenerator exit are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Properties The properties of air at $500^\circ\text{C} = 773\text{ K}$ are $c_p = 1.093\text{ kJ/kg}\cdot\text{K}$, $c_v = 0.806\text{ kJ/kg}\cdot\text{K}$, $R = 0.287\text{ kJ/kg}\cdot\text{K}$, and $k = 1.357$ (Table A-2b).

Analysis (a) For the compressor and the turbine:

$$T_{2s} = T_1 \left(\frac{P_2}{P_1} \right)^{\frac{k-1}{k}} = (303\text{ K}) \left(\frac{700\text{ kPa}}{100\text{ kPa}} \right)^{\frac{1.357-1}{1.357}} = 505.6\text{ K}$$

$$\eta_c = \frac{T_{2s} - T_1}{T_2 - T_1} = \frac{(505.6 - 303)\text{ K}}{(533 - 303)\text{ K}} = \mathbf{0.881}$$

$$T_{4s} = T_3 \left(\frac{P_4}{P_3} \right)^{\frac{k-1}{k}} = (1144\text{ K}) \left(\frac{100\text{ kPa}}{700\text{ kPa}} \right)^{\frac{1.357-1}{1.357}} = 685.6\text{ K}$$

$$\eta_T = \frac{T_3 - T_4}{T_3 - T_{4s}} \rightarrow 0.85 = \frac{(1144 - T_4)\text{ K}}{(1144 - 685.6)\text{ K}} \rightarrow T_4 = 754.4\text{ K}$$

(b) The effectiveness of the regenerator is

$$\varepsilon_{\text{regen}} = \frac{T_5 - T_2}{T_4 - T_2} = \frac{(673 - 533)\text{ K}}{(754.4 - 533)\text{ K}} = \mathbf{0.632}$$

(c) The fuel rate and air-fuel ratio are

$$\dot{Q}_{\text{in}} = \dot{m}_f q_{\text{HV}} \eta_c = (\dot{m}_f + \dot{m}_a) c_p (T_3 - T_5)$$

$$\dot{m}_f (42,000\text{ kJ/kg})(0.97) = (\dot{m}_f + 12.6)(1.093\text{ kJ/kg}\cdot\text{K})(1144 - 673)\text{ K} \rightarrow \dot{m}_f = 0.1613\text{ kg/s}$$

$$\text{AF} = \frac{\dot{m}_a}{\dot{m}_f} = \frac{12.6}{0.1613} = \mathbf{78.14}$$

Also,

$$\dot{m} = \dot{m}_a + \dot{m}_f = 12.6 + 0.1613 = 12.76\text{ kg/s}$$

$$\dot{Q}_{\text{in}} = \dot{m}_f q_{\text{HV}} \eta_c = (0.1613\text{ kg/s})(42,000\text{ kJ/kg})(0.97) = 6570\text{ kW}$$

(d) The net power and the back work ratio are

$$\dot{W}_{\text{C,in}} = \dot{m}_a c_p (T_2 - T_1) = (12.6\text{ kg/s})(1.093\text{ kJ/kg}\cdot\text{K})(533 - 303)\text{ K} = 3168\text{ kW}$$

$$\dot{W}_{\text{T,out}} = \dot{m} c_p (T_3 - T_4) = (12.76\text{ kg/s})(1.093\text{ kJ/kg}\cdot\text{K})(1144 - 754.4)\text{ K} = 5434\text{ kW}$$

$$\dot{W}_{\text{net}} = \dot{W}_{\text{T,out}} - \dot{W}_{\text{C,in}} = 5434 - 3168 = \mathbf{2267\text{ kW}}$$

$$r_{\text{bw}} = \frac{\dot{W}_{\text{C,in}}}{\dot{W}_{\text{T,out}}} = \frac{3168\text{ kW}}{5434\text{ kW}} = \mathbf{0.583}$$

(e) The thermal efficiency is

$$\eta_{th} = \frac{\dot{W}_{net}}{\dot{Q}_{in}} = \frac{2267 \text{ kW}}{6570 \text{ kW}} = \mathbf{0.345}$$

(f) The second-law efficiency of the cycle is defined as the ratio of actual thermal efficiency to the maximum possible thermal efficiency (Carnot efficiency). The maximum temperature for the cycle can be taken to be the turbine inlet temperature. That is,

$$\eta_{max} = 1 - \frac{T_1}{T_3} = 1 - \frac{303 \text{ K}}{1144 \text{ K}} = 0.735$$

and

$$\eta_{II} = \frac{\eta_{th}}{\eta_{max}} = \frac{0.345}{0.735} = \mathbf{0.469}$$

(g) The exergy efficiency for the compressor is defined as the ratio of stream exergy difference between the inlet and exit of the compressor to the actual power input:

$$\begin{aligned} \Delta \dot{X}_C &= \dot{m}_a [h_2 - h_1 - T_0 (s_2 - s_1)] = \dot{m}_a \left\{ c_p (T_2 - T_1) - T_0 \left[c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \right] \right\} \\ &= (12.6) \left\{ (1.093)(533 - 303) - (303) \left[(1.093) \ln \left(\frac{533}{303} \right) - 0.287 \ln \left(\frac{700}{100} \right) \right] \right\} \\ &= 2943 \text{ kW} \\ \eta_{II,C} &= \frac{\Delta \dot{X}_C}{\dot{W}_{C,in}} = \frac{2943 \text{ kW}}{3168 \text{ kW}} = \mathbf{0.929} \end{aligned}$$

The exergy efficiency for the turbine is defined as the ratio of actual turbine power to the stream exergy difference between the inlet and exit of the turbine:

$$\begin{aligned} \Delta \dot{X}_T &= \dot{m} \left\{ c_p (T_3 - T_4) - T_0 \left[c_p \ln \frac{T_3}{T_4} - R \ln \frac{P_3}{P_4} \right] \right\} \\ &= (12.76) \left\{ (1.093)(1144 - 754.4) - (303) \left[(1.093) \ln \left(\frac{1144}{754.4} \right) - 0.287 \ln \left(\frac{700}{100} \right) \right] \right\} \\ &= 5834 \text{ kW} \\ \eta_{II,T} &= \frac{\dot{W}_{T,in}}{\Delta \dot{X}_T} = \frac{5434 \text{ kW}}{5834 \text{ kW}} = \mathbf{0.932} \end{aligned}$$

An energy balance on the regenerator gives

$$\begin{aligned} \dot{m}_a c_p (T_5 - T_2) &= \dot{m} c_p (T_4 - T_6) \\ (12.6)(1.093)(673 - 533) &= (12.76)(1.093)(754.4 - T_6) \longrightarrow T_6 = 616.2 \text{ K} \end{aligned}$$

The exergy efficiency for the regenerator is defined as the ratio of the exergy increase of the cold fluid to the exergy decrease of the hot fluid:

$$\begin{aligned} \Delta \dot{X}_{regen,hot} &= \dot{m} \left\{ c_p (T_4 - T_6) - T_0 \left[c_p \ln \frac{T_4}{T_6} - 0 \right] \right\} \\ &= (12.76) \left\{ (1.093)(754.4 - 616.2) - (303) \left[(1.093) \ln \left(\frac{754.4}{616.2} \right) - 0 \right] \right\} \\ &= 1073 \text{ kW} \end{aligned}$$

$$\begin{aligned}\Delta\dot{X}_{\text{regen,cold}} &= \dot{m} \left\{ c_p (T_5 - T_2) - T_0 \left[c_p \ln \frac{T_5}{T_2} - 0 \right] \right\} \\ &= (12.76) \left\{ (1.093)(673 - 533) - (303) \left[(1.093) \ln \left(\frac{673}{533} \right) - 0 \right] \right\} \\ &= 954.8 \text{ kW}\end{aligned}$$

$$\eta_{II,T} = \frac{\Delta\dot{X}_{\text{regen,cold}}}{\Delta\dot{X}_{\text{regen,hot}}} = \frac{954.8 \text{ kW}}{1073 \text{ kW}} = \mathbf{0.890}$$

The exergy of the combustion gases at the regenerator exit:

$$\begin{aligned}\dot{X}_6 &= \dot{m} \left\{ c_p (T_6 - T_0) - T_0 \left[c_p \ln \frac{T_6}{T_0} - 0 \right] \right\} \\ &= (12.76) \left\{ (1.093)(616.2 - 303) - (303) \left[(1.093) \ln \left(\frac{616.2}{303} \right) - 0 \right] \right\} \\ &= \mathbf{1351 \text{ kW}}\end{aligned}$$

9-149 A modern compression ignition engine operates on the ideal dual cycle. The maximum temperature in the cycle, the net work output, the thermal efficiency, the mean effective pressure, the net power output, the second-law efficiency of the cycle, and the rate of exergy of the exhaust gases are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Properties The properties of air at 1000 K are $c_p = 1.142 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.855 \text{ kJ/kg}\cdot\text{K}$, $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.336$ (Table A-2b).

Analysis (a) The clearance volume and the total volume of the engine at the beginning of compression process (state 1) are

$$r = \frac{V_c + V_d}{V_c} \rightarrow 16 = \frac{V_c + 0.0018 \text{ m}^3}{V_c} \rightarrow V_c = 0.00012 \text{ m}^3 = V_2 = V_x$$

$$V_1 = V_c + V_d = 0.00012 + 0.0018 = 0.00192 \text{ m}^3 = V_4$$

Process 1-2: Isentropic compression

$$T_2 = T_1 \left(\frac{V_1}{V_2} \right)^{k-1} = (343 \text{ K})(16)^{1.3361} = 870.7 \text{ K}$$

$$P_2 = P_1 \left(\frac{V_1}{V_2} \right)^k = (95 \text{ kPa})(16)^{1.336} = 3859 \text{ kPa}$$

Process 2-x and x-3: Constant-volume and constant pressure heat addition processes:

$$T_x = T_2 \frac{P_x}{P_2} = (870.7 \text{ K}) \frac{7500 \text{ kPa}}{3859 \text{ kPa}} = 1692 \text{ K}$$

$$q_{2-x} = c_v(T_x - T_2) = (0.855 \text{ kJ/kg}\cdot\text{K})(1692 - 870.7) \text{ K} = 702.6 \text{ kJ/kg}$$

$$q_{2-x} = q_{x-3} = c_p(T_3 - T_x) \rightarrow 702.6 \text{ kJ/kg} = (0.855 \text{ kJ/kg}\cdot\text{K})(T_3 - 1692) \text{ K} \rightarrow T_3 = \mathbf{2308 \text{ K}}$$

(b) $q_{in} = q_{2-x} + q_{x-3} = 702.6 + 702.6 = 1405 \text{ kJ/kg}$

$$V_3 = V_x \frac{T_3}{T_x} = (0.00012 \text{ m}^3) \frac{2308 \text{ K}}{1692 \text{ K}} = 0.0001636 \text{ m}^3$$

Process 3-4: isentropic expansion.

$$T_4 = T_3 \left(\frac{V_3}{V_4} \right)^{k-1} = (2308 \text{ K}) \left(\frac{0.0001636 \text{ m}^3}{0.00192 \text{ m}^3} \right)^{1.3361} = 1009 \text{ K}$$

$$P_4 = P_3 \left(\frac{V_3}{V_4} \right)^k = (7500 \text{ kPa}) \left(\frac{0.0001636 \text{ m}^3}{0.00192 \text{ m}^3} \right)^{1.336} = 279.4 \text{ kPa}$$

Process 4-1: constant volume heat rejection.

$$q_{out} = c_v(T_4 - T_1) = (0.855 \text{ kJ/kg}\cdot\text{K})(1009 - 343) \text{ K} = 569.3 \text{ kJ/kg}$$

The net work output and the thermal efficiency are

$$w_{net,out} = q_{in} - q_{out} = 1405 - 569.3 = \mathbf{835.8 \text{ kJ/kg}}$$

$$\eta_{th} = \frac{w_{net,out}}{q_{in}} = \frac{835.8 \text{ kJ/kg}}{1405 \text{ kJ/kg}} = 0.5948 = \mathbf{59.5\%}$$

(c) The mean effective pressure is determined to be

$$m = \frac{P_1 v_1}{RT_1} = \frac{(95 \text{ kPa})(0.00192 \text{ m}^3)}{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(343 \text{ K})} = 0.001853 \text{ kg}$$

$$\text{MEP} = \frac{mw_{\text{net,out}}}{v_1 - v_2} = \frac{(0.001853 \text{ kg})(835.8 \text{ kJ/kg})}{(0.00192 - 0.00012) \text{ m}^3} \left(\frac{\text{kPa} \cdot \text{m}^3}{\text{kJ}} \right) = \mathbf{860.4 \text{ kPa}}$$

(d) The power for engine speed of 3500 rpm is

$$\dot{W}_{\text{net}} = mw_{\text{net}} \frac{\dot{n}}{2} = (0.001853 \text{ kg})(835.8 \text{ kJ/kg}) \frac{2200 \text{ (rev/min)}}{(2 \text{ rev/cycle})} \left(\frac{1 \text{ min}}{60 \text{ s}} \right) = \mathbf{28.39 \text{ kW}}$$

Note that there are two revolutions in one cycle in four-stroke engines.

(e) The second-law efficiency of the cycle is defined as the ratio of actual thermal efficiency to the maximum possible thermal efficiency (Carnot efficiency). We take the dead state temperature and pressure to be 25°C and 100 kPa.

$$\eta_{\text{max}} = 1 - \frac{T_0}{T_3} = 1 - \frac{(25 + 273) \text{ K}}{2308 \text{ K}} = 0.8709$$

and

$$\eta_{\text{II}} = \frac{\eta_{\text{th}}}{\eta_{\text{max}}} = \frac{0.5948}{0.8709} = 0.683 = \mathbf{68.3\%}$$

The rate of exergy of the exhaust gases is determined as follows

$$v_4 = \frac{v_4}{m} = \frac{0.00192 \text{ m}^3}{0.001853 \text{ kg}} = 1.036 \text{ m}^3/\text{kg}$$

$$v_0 = \frac{RT_0}{P_0} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(298 \text{ K})}{100 \text{ kPa}} = 0.8553 \text{ m}^3/\text{kg}$$

$$\begin{aligned} x_4 &= u_4 - u_0 + P_0(v_4 - v_0) - T_0(s_4 - s_0) = c_v(T_4 - T_0) + P_0(v_4 - v_0) - T_0 \left[c_p \ln \frac{T_4}{T_0} - R \ln \frac{P_4}{P_0} \right] \\ &= (0.855)(1009 - 298) + (100 \text{ kPa})(1.036 - 0.8533) \text{ m}^3/\text{kg} \\ &\quad - (298 \text{ K}) \left[(1.142 \text{ kJ/kg} \cdot \text{K}) \ln \frac{1009}{298} - (0.287 \text{ kJ/kg} \cdot \text{K}) \ln \frac{279.4}{100} \right] \\ &= 303.3 \text{ kJ/kg} \end{aligned}$$

$$\dot{X}_4 = mx_4 \frac{\dot{n}}{2} = (0.001853 \text{ kg})(303.3 \text{ kJ/kg}) \frac{2200 \text{ (rev/min)}}{(2 \text{ rev/cycle})} \left(\frac{1 \text{ min}}{60 \text{ s}} \right) = \mathbf{10.30 \text{ kW}}$$

Review Problems

9-150 A Carnot cycle executed in a closed system uses air as the working fluid. The net work output per cycle is to be determined.

Assumptions 1 Air is an ideal gas with variable specific heats.

Properties The gas constant of air is $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ (Table A-1).

Analysis (a) The maximum temperature is determined from

$$\eta_{th} = 1 - \frac{T_L}{T_H} \longrightarrow 0.60 = 1 - \frac{300 \text{ K}}{T_H} \longrightarrow T_H = 750 \text{ K}$$

$$\begin{aligned} s_2 - s_1 &= s_2^{\circ} - s_1^{\circ} - R \ln \frac{P_2}{P_1} = -(0.287 \text{ kJ/kg}\cdot\text{K}) \ln \frac{700 \text{ kPa}}{1000 \text{ kPa}} \\ &= 0.1204 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

$$\begin{aligned} W_{net} &= m(s_2 - s_1)(T_H - T_L) \\ &= (0.0025 \text{ kg})(0.1024 \text{ kJ/kg}\cdot\text{K})(750 - 300)\text{K} \\ &= \mathbf{0.115 \text{ kJ}} \end{aligned}$$

9-151 The four processes of an air-standard cycle are described. The cycle is to be shown on P - v and T - s diagrams, and the net work output and the thermal efficiency are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with variable specific heats.

Properties The properties of air are given in Table A-17.

Analysis (b) We treat air as an ideal gas with variable specific heats,

$$T_1 = 300 \text{ K} \longrightarrow u_1 = 214.07 \text{ kJ/kg}$$

$$h_1 = 300.19 \text{ kJ/kg}$$

$$\frac{P_2 v_2}{T_2} = \frac{P_1 v_1}{T_1} \longrightarrow T_2 = \frac{P_2}{P_1} T_1 = \left(\frac{300 \text{ kPa}}{100 \text{ kPa}} \right) (300 \text{ K})$$

$$= 900 \text{ K} \longrightarrow u_2 = 674.58 \text{ kJ/kg}$$

$$h_2 = 932.93 \text{ kJ/kg}$$

$$T_3 = 1300 \text{ K} \longrightarrow u_3 = 1022.82 \text{ kJ/kg}$$

$$h_3 = 1395.97 \text{ kJ/kg}, P_{r3} = 330.9$$

$$P_{r4} = \frac{P_4}{P_3} P_{r3} = \left(\frac{100 \text{ kPa}}{300 \text{ kPa}} \right) (330.9) = 110.3$$

$$\longrightarrow h_4 = 1036.46 \text{ kJ/kg}$$

$$\begin{aligned} q_{\text{in}} &= q_{12, \text{in}} + q_{23, \text{in}} = (u_2 - u_1) + (h_3 - h_2) \\ &= (674.58 - 214.07) + (1395.97 - 932.93) \\ &= 923.55 \text{ kJ/kg} \end{aligned}$$

$$q_{\text{out}} = h_4 - h_1 = 1036.46 - 300.19 = 736.27 \text{ kJ/kg}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 923.55 - 736.27 = \mathbf{187.28 \text{ kJ/kg}}$$

$$(c) \quad \eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{187.28 \text{ kJ/kg}}{923.55 \text{ kJ/kg}} = \mathbf{20.3\%}$$

9-152 All four processes of an air-standard cycle are described. The cycle is to be shown on P - v and T - s diagrams, and the net work output and the thermal efficiency are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2).

Analysis (b) Process 3-4 is isentropic:

$$T_4 = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = (1300 \text{ K}) \left(\frac{1}{3} \right)^{0.4/1.4} = 949.8 \text{ K}$$

$$\frac{P_2 v_2}{T_2} = \frac{P_1 v_1}{T_1} \longrightarrow T_2 = \frac{P_2}{P_1} T_1 = \left(\frac{300 \text{ kPa}}{100 \text{ kPa}} \right) (300 \text{ K}) = 900 \text{ K}$$

$$\begin{aligned} q_{\text{in}} &= q_{12,\text{in}} + q_{23,\text{in}} = (u_2 - u_1) + (h_3 - h_2) = c_v(T_2 - T_1) + c_p(T_3 - T_2) \\ &= (0.718 \text{ kJ/kg}\cdot\text{K})(900 - 300)\text{K} + (1.005 \text{ kJ/kg}\cdot\text{K})(1300 - 900)\text{K} \\ &= 832.8 \text{ kJ/kg} \end{aligned}$$

$$\begin{aligned} q_{\text{out}} &= h_4 - h_1 = c_p(T_4 - T_1) = (1.005 \text{ kJ/kg}\cdot\text{K})(949.8 - 300)\text{K} \\ &= 653 \text{ kJ/kg} \end{aligned}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 832.8 - 653 = \mathbf{179.8 \text{ kJ/kg}}$$

$$(c) \quad \eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{179.8 \text{ kJ/kg}}{832.8 \text{ kJ/kg}} = \mathbf{21.6\%}$$

9-153 An Otto cycle with a compression ratio of 10.5 is considered. The thermal efficiency is to be determined using constant and variable specific heats.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible.

Properties The properties of air at room temperature are $R = 0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K}$, $c_p = 1.005 \text{ kJ/kg} \cdot \text{K}$, $c_v = 0.718 \text{ kJ/kg} \cdot \text{K}$, and $k = 1.4$ (Table A-2a).

Analysis (a) Constant specific heats:

$$\eta_{\text{th}} = 1 - \frac{1}{r^{k-1}} = 1 - \frac{1}{10.5^{1.4-1}} = 0.6096 = \mathbf{61.0\%}$$

(b) Variable specific heats: (using air properties from Table A-17)

Process 1-2: isentropic compression.

$$T_1 = 308 \text{ K} \longrightarrow \begin{aligned} u_1 &= 219.82 \text{ kJ/kg} \\ v_{r1} &= 581.8 \end{aligned}$$

$$v_{r2} = \frac{v_2}{v_1} v_{r1} = \frac{1}{r} v_{r1} = \frac{1}{10.5} (581.8) = 55.41 \longrightarrow u_2 = 560.55 \text{ kJ/kg}$$

Process 2-3: $v = \text{constant}$ heat addition.

$$T_3 = 1273 \text{ K} \longrightarrow \begin{aligned} u_3 &= 998.51 \text{ kJ/kg} \\ v_{r3} &= 12.045 \end{aligned}$$

$$q_{\text{in}} = u_3 - u_2 = 998.51 - 560.55 = 437.96 \text{ kJ/kg}$$

Process 3-4: isentropic expansion.

$$v_{r4} = \frac{v_4}{v_3} v_{r3} = r v_{r3} = (10.5)(12.045) = 126.5 \longrightarrow u_4 = 405.11 \text{ kJ/kg}$$

Process 4-1: $v = \text{constant}$ heat rejection.

$$q_{\text{out}} = u_4 - u_1 = 405.11 - 219.82 = 185.29 \text{ kJ/kg}$$

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{185.29 \text{ kJ/kg}}{437.96 \text{ kJ/kg}} = 0.5769 = \mathbf{57.7\%}$$

9-154E An ideal diesel engine with air as the working fluid has a compression ratio of 20. The thermal efficiency is to be determined using constant and variable specific heats.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 0.240$ Btu/lbm·R, $c_v = 0.171$ Btu/lbm·R, $R = 0.06855$ Btu/lbm·R, and $k = 1.4$ (Table A-2Ea).

Analysis (a) Constant specific heats:

Process 1-2: isentropic compression.

$$T_2 = T_1 \left(\frac{v_1}{v_2} \right)^{k-1} = (505 \text{ R})(20)^{0.4} = 1673.8 \text{ R}$$

Process 2-3: $P = \text{constant}$ heat addition.

$$\frac{P_3 v_3}{T_3} = \frac{P_2 v_2}{T_2} \longrightarrow \frac{v_3}{v_2} = \frac{T_3}{T_2} = \frac{2260 \text{ R}}{1673.8 \text{ R}} = 1.350$$

Process 3-4: isentropic expansion.

$$T_4 = T_3 \left(\frac{v_3}{v_4} \right)^{k-1} = T_3 \left(\frac{1.350 v_2}{v_4} \right)^{k-1} = T_3 \left(\frac{1.350}{r} \right)^{k-1} = (2260 \text{ R}) \left(\frac{1.350}{20} \right)^{0.4} = 768.8 \text{ R}$$

$$q_{\text{in}} = h_3 - h_2 = c_p (T_3 - T_2) = (0.240 \text{ Btu/lbm} \cdot \text{R})(2260 - 1673.8) \text{ R} = 140.7 \text{ Btu/lbm}$$

$$q_{\text{out}} = u_4 - u_1 = c_v (T_4 - T_1) = (0.171 \text{ Btu/lbm} \cdot \text{R})(768.8 - 505) \text{ R} = 45.11 \text{ Btu/lbm}$$

$$w_{\text{net,out}} = q_{\text{in}} - q_{\text{out}} = 140.7 - 45.11 = 95.59 \text{ Btu/lbm}$$

$$\eta_{\text{th}} = \frac{w_{\text{net,out}}}{q_{\text{in}}} = \frac{95.59 \text{ Btu/lbm}}{140.7 \text{ Btu/lbm}} = 0.6794 = \mathbf{67.9\%}$$

(b) Variable specific heats: (using air properties from Table A-17)

Process 1-2: isentropic compression.

$$T_1 = 505 \text{ R} \longrightarrow \begin{aligned} u_1 &= 86.06 \text{ Btu/lbm} \\ v_{r1} &= 170.82 \end{aligned}$$

$$v_{r2} = \frac{v_2}{v_1} v_{r1} = \frac{1}{r} v_{r1} = \frac{1}{20} (170.82) = 8.541 \longrightarrow \begin{aligned} T_2 &= 1582.3 \text{ R} \\ h_2 &= 391.01 \text{ Btu/lbm} \end{aligned}$$

Process 2-3: $P = \text{constant}$ heat addition.

$$\frac{P_3 v_3}{T_3} = \frac{P_2 v_2}{T_2} \longrightarrow \frac{v_3}{v_2} = \frac{T_3}{T_2} = \frac{2260 \text{ R}}{1582.3 \text{ R}} = 1.428$$

$$T_3 = 2260 \text{ R} \longrightarrow \begin{aligned} h_3 &= 577.52 \text{ Btu/lbm} \\ v_{r3} &= 2.922 \end{aligned}$$

$$q_{\text{in}} = h_3 - h_2 = 577.52 - 391.01 = 186.51 \text{ Btu/lbm}$$

Process 3-4: isentropic expansion.

$$v_{r4} = \frac{v_4}{v_3} v_{r3} = \frac{v_4}{1.428 v_2} v_{r3} = \frac{r}{1.428} v_{r3} = \frac{20}{1.428} (2.922) = 40.92 \longrightarrow u_4 = 152.65 \text{ Btu/lbm}$$

Process 4-1: $v = \text{constant}$ heat rejection.

$$q_{\text{out}} = u_4 - u_1 = 152.65 - 86.06 = 66.59 \text{ Btu/lbm}$$

$$\text{Then } \eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{66.59 \text{ Btu/lbm}}{186.51 \text{ Btu/lbm}} = 0.6430 = \mathbf{64.3\%}$$

9-155E A simple ideal Brayton cycle with air as the working fluid operates between the specified temperature limits. The net work is to be determined using constant and variable specific heats.

Assumptions 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable. 3 Kinetic and potential energy changes are negligible.

Properties The properties of air at room temperature are $c_p = 0.240$ Btu/lbm·R and $k = 1.4$ (Table A-2Ea).

Analysis (a) Constant specific heats:

$$T_2 = T_1 r_p^{(k-1)/k} = (480 \text{ R})(12)^{0.4/1.4} = 976.3 \text{ R}$$

$$T_4 = T_3 \left(\frac{1}{r_p} \right)^{(k-1)/k} = (1460 \text{ R}) \left(\frac{1}{12} \right)^{0.4/1.4} = 717.8 \text{ R}$$

$$\begin{aligned} w_{\text{net}} &= w_{\text{turb}} - w_{\text{comp}} \\ &= c_p (T_3 - T_4) - c_p (T_2 - T_1) \\ &= c_p (T_3 - T_4 + T_1 - T_2) \\ &= (0.240 \text{ Btu/lbm} \cdot \text{R})(1460 - 717.8 + 480 - 976.3) \text{ R} \\ &= \mathbf{59.0 \text{ Btu/lbm}} \end{aligned}$$

(b) Variable specific heats: (using air properties from Table A-17E)

$$T_1 = 480 \text{ R} \longrightarrow \begin{aligned} h_1 &= 114.69 \text{ Btu/lbm} \\ P_{r1} &= 0.9182 \end{aligned}$$

$$P_{r2} = \frac{P_2}{P_1} P_{r1} = (12)(0.9182) = 11.02 \longrightarrow h_2 = 233.63 \text{ Btu/lbm}$$

$$T_3 = 1460 \text{ R} \longrightarrow \begin{aligned} h_3 &= 358.63 \text{ Btu/lbm} \\ P_{r3} &= 50.40 \end{aligned}$$

$$P_{r4} = \frac{P_4}{P_3} P_{r3} = \left(\frac{1}{12} \right) (50.40) = 4.12 \longrightarrow h_4 = 176.32 \text{ Btu/lbm}$$

$$\begin{aligned} w_{\text{net}} &= w_{\text{turb}} - w_{\text{comp}} \\ &= (h_3 - h_4) - (h_2 - h_1) \\ &= (358.63 - 176.32) - (233.63 - 114.69) \\ &= \mathbf{63.4 \text{ Btu/lbm}} \end{aligned}$$

9-156 A turbocharged four-stroke V-16 diesel engine produces 4400 hp at 1500 rpm. The amount of work produced per cylinder per mechanical and per thermodynamic cycle is to be determined.

Analysis Noting that there are 16 cylinders and each thermodynamic cycle corresponds to 2 mechanical cycles (revolutions), we have

(a)

$$\begin{aligned} w_{\text{mechanical}} &= \frac{\text{Total power produced}}{(\text{No. of cylinders})(\text{No. of mechanical cycles})} \\ &= \frac{4400 \text{ hp}}{(16 \text{ cylinders})(1500 \text{ rev/min})} \left(\frac{42.41 \text{ Btu/min}}{1 \text{ hp}} \right) \\ &= \mathbf{7.78 \text{ Btu/cyl} \cdot \text{mech cycle}} \quad (= 7.37 \text{ kJ/cyl} \cdot \text{mech cycle}) \end{aligned}$$

(b)

$$\begin{aligned} w_{\text{thermodynamic}} &= \frac{\text{Total power produced}}{(\text{No. of cylinders})(\text{No. of thermodynamic cycles})} \\ &= \frac{4400 \text{ hp}}{(16 \text{ cylinders})(1500/2 \text{ rev/min})} \left(\frac{42.41 \text{ Btu/min}}{1 \text{ hp}} \right) \\ &= \mathbf{15.55 \text{ Btu/cyl} \cdot \text{therm cycle}} \quad (= 14.74 \text{ kJ/cyl} \cdot \text{therm cycle}) \end{aligned}$$

9-157 A simple ideal Brayton cycle operating between the specified temperature limits is considered. The pressure ratio for which the compressor and the turbine exit temperature of air are equal is to be determined.

Assumptions 1 Steady operating conditions exist. **2** The air-standard assumptions are applicable. **3** Kinetic and potential energy changes are negligible. **4** Air is an ideal gas with constant specific heats.

Properties The specific heat ratio of air is $k=1.4$ (Table A-2).

Analysis We treat air as an ideal gas with constant specific heats. Using the isentropic relations, the temperatures at the compressor and turbine exit can be expressed as

$$\begin{aligned} T_2 &= T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = T_1 (r_p)^{(k-1)/k} \\ T_4 &= T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = T_3 \left(\frac{1}{r_p} \right)^{(k-1)/k} \end{aligned}$$

Setting $T_2 = T_4$ and solving for r_p gives

$$r_p = \left(\frac{T_3}{T_1} \right)^{k/2(k-1)} = \left(\frac{1500 \text{ K}}{300 \text{ K}} \right)^{1.4/0.8} = \mathbf{16.7}$$

Therefore, the compressor and turbine exit temperatures will be equal when the compression ratio is 16.7.

9-158 A spark-ignition engine operates on an ideal Otto cycle with a compression ratio of 11. The maximum temperature and pressure in the cycle, the net work per cycle and per cylinder, the thermal efficiency, the mean effective pressure, and the power output for a specified engine speed are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with variable specific heats.

Properties The gas constant of air is $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ (Table A-1).

Analysis (a) First the mass in one cylinder is determined as follows

$$r = \frac{V_c + V_d}{V_c} \rightarrow 11 = \frac{V_c + (0.0018)/4}{V_c} \rightarrow V_c = 0.000045 \text{ m}^3 \text{ for one cylinder}$$

$$V_1 = V_c + V_d = 0.000045 + 0.00045 = 0.000495 \text{ m}^3$$

$$m = \frac{P_1 V_1}{RT_1} = \frac{(90 \text{ kPa})(0.000495 \text{ m}^3)}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(323 \text{ K})} = 0.0004805 \text{ kg}$$

For this problem, we use the properties from EES software. Remember that for an ideal gas, enthalpy is a function of temperature only whereas entropy is functions of both temperature and pressure.

Process 1-2: Isentropic compression

$$T_1 = 50^\circ\text{C} = 323 \text{ K} \rightarrow u_1 = 230.88 \text{ kJ/kg}$$

$$\left. \begin{array}{l} T_1 = 50^\circ\text{C} = 323 \text{ K} \\ P_1 = 90 \text{ kPa} \end{array} \right\} s_1 = 5.8100 \text{ kJ/kg}\cdot\text{K}$$

$$v_1 = \frac{V_1}{m} = \frac{0.000495 \text{ m}^3}{0.0004805 \text{ kg}} = 1.0302 \text{ m}^3/\text{kg}$$

$$V_2 = V_c = 0.000045 \text{ m}^3$$

$$v_2 = \frac{V_2}{m} = \frac{0.000045 \text{ m}^3}{0.0004805 \text{ kg}} = 0.09364 \text{ m}^3/\text{kg}$$

$$\left. \begin{array}{l} s_2 = s_1 = 5.8100 \text{ kJ/kg}\cdot\text{K} \\ v_2 = 0.09364 \text{ m}^3/\text{kg} \end{array} \right\} T_2 = 807.3 \text{ K}$$

$$T_2 = 807.3 \text{ K} \rightarrow u_2 = 598.33 \text{ kJ/kg}$$

$$P_2 = P_1 \frac{v_1}{v_2} \frac{T_2}{T_1} = (90 \text{ kPa}) \left(\frac{0.000495 \text{ m}^3}{0.000045 \text{ m}^3} \right) \left(\frac{807.3 \text{ K}}{323 \text{ K}} \right) = 2474 \text{ kPa}$$

Process 2-3: constant volume heat addition

$$Q_{\text{in}} = m(u_3 - u_2) \rightarrow 1.5 \text{ kJ} = (0.0004805 \text{ kg})(u_3 - 598.33 \text{ kJ/kg}) \rightarrow u_3 = 3719.8 \text{ kJ/kg}$$

$$u_2 = 598.33 \text{ kJ/kg} \rightarrow T_3 = \mathbf{4037 \text{ K}}$$

$$P_3 = P_2 \left(\frac{T_3}{T_2} \right) = (2474 \text{ kPa}) \left(\frac{4037 \text{ K}}{807.3 \text{ K}} \right) = \mathbf{12,375 \text{ kPa}}$$

$$\left. \begin{array}{l} T_3 = 4037 \text{ K} \\ P_3 = 12,375 \text{ kPa} \end{array} \right\} s_3 = 7.3218 \text{ kJ/kg}\cdot\text{K}$$

(b) Process 3-4: isentropic expansion.

$$\left. \begin{array}{l} s_4 = s_3 = 7.3218 \text{ kJ/kg}\cdot\text{K} \\ v_4 = v_1 = 1.0302 \text{ m}^3/\text{kg} \end{array} \right\} T_4 = 2028 \text{ K}$$

$$T_4 = 2028 \text{ K} \longrightarrow u_4 = 1703.6 \text{ kJ/kg}$$

$$P_4 = P_3 \frac{V_3}{V_4} \frac{T_4}{T_3} = (12,375 \text{ kPa}) \left(\frac{1}{11} \right) \left(\frac{2028 \text{ K}}{4037 \text{ K}} \right) = 565 \text{ kPa}$$

Process 4-1: constant volume heat rejection

$$Q_{\text{out}} = m(u_4 - u_1) = (0.0004805 \text{ kg})(1703.6 - 230.88) \text{ kJ/kg} = 0.7077 \text{ kJ}$$

The net work output and the thermal efficiency are

$$W_{\text{net,out}} = Q_{\text{in}} - Q_{\text{out}} = 1.5 - 0.7077 = \mathbf{0.792 \text{ kJ}} \text{ (per cycle per cylinder)}$$

$$\eta_{\text{th}} = \frac{W_{\text{net,out}}}{Q_{\text{in}}} = \frac{0.792 \text{ kJ}}{1.5 \text{ kJ}} = \mathbf{0.528}$$

(c) The mean effective pressure is determined to be

$$\text{MEP} = \frac{W_{\text{net,out}}}{V_1 - V_2} = \frac{0.7923 \text{ kJ}}{(0.000495 - 0.000045) \text{ m}^3} \left(\frac{\text{kPa} \cdot \text{m}^3}{\text{kJ}} \right) = \mathbf{1761 \text{ kPa}}$$

(d) The power for engine speed of 3000 rpm is

$$\dot{W}_{\text{net}} = n_{\text{cyl}} W_{\text{net}} \frac{\dot{n}}{n_{\text{rev}}} = (4 \text{ cylinder})(0.792 \text{ kJ/cylinder - cycle}) \frac{(3000 \text{ rev/min}) \left(\frac{1 \text{ min}}{60 \text{ s}} \right)}{(2 \text{ rev/cycle})} = \mathbf{79.2 \text{ kW}}$$

Note that there are two revolutions in one cycle in four-stroke engines.

9-159  A four-cylinder spark-ignition engine with a compression ratio of 8 is considered. The amount of heat supplied per cylinder, the thermal efficiency, and the rpm for a net power output of 60 kW are to be determined.

Assumptions **1** The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with variable specific heats.

Properties The gas constant of air is $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ (Table A-1). The properties of air are given in Table A-17.

Analysis (a) Process 1-2: isentropic compression.

$$T_1 = 310 \text{ K} \longrightarrow u_1 = 221.25 \text{ kJ/kg}$$

$$v_{r_1} = 572.3$$

$$v_{r_2} = \frac{v_2}{v_1} v_{r_1} = \frac{1}{r} v_{r_1} = \frac{1}{10.5} (572.3) = 54.50$$

$$\longrightarrow u_2 = 564.29 \text{ kJ/kg}$$

Process 2-3: $v = \text{constant}$ heat addition.

$$T_3 = 2100 \text{ K} \longrightarrow u_3 = 1775.3 \text{ kJ/kg}$$

$$v_{r_3} = 2.356$$

$$m = \frac{P_1 V_1}{RT_1} = \frac{(98 \text{ kPa})(0.0004 \text{ m}^3)}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(310 \text{ K})} = 4.406 \times 10^{-4} \text{ kg}$$

$$Q_{\text{in}} = m(u_3 - u_2) = (4.406 \times 10^{-4} \text{ kg})(1775.3 - 564.29) \text{ kJ/kg} = \mathbf{0.5336 \text{ kJ}}$$

(b) Process 3-4: isentropic expansion.

$$v_{r_4} = \frac{v_4}{v_3} v_{r_3} = r v_{r_3} = (10.5)(2.356) = 24.74 \longrightarrow u_4 = 764.05 \text{ kJ/kg}$$

Process 4-1: $v = \text{constant}$ heat rejection.

$$Q_{\text{out}} = m(u_4 - u_1) = (4.406 \times 10^{-4} \text{ kg})(764.05 - 221.25) \text{ kJ/kg} = 0.2392 \text{ kJ}$$

$$W_{\text{net}} = Q_{\text{in}} - Q_{\text{out}} = 0.5336 - 0.2392 = 0.2944 \text{ kJ}$$

$$\eta_{\text{th}} = \frac{W_{\text{net}}}{Q_{\text{in}}} = \frac{0.2944 \text{ kJ}}{0.5336 \text{ kJ}} = 0.5517 = \mathbf{55.2\%}$$

$$(c) \quad \dot{n} = 2 \frac{\dot{W}_{\text{net}}}{n_{\text{cyl}} W_{\text{net,cyl}}} = (2 \text{ rev/cycle}) \frac{45 \text{ kJ/s}}{4 \times (0.2944 \text{ kJ/cycle})} \left(\frac{60 \text{ s}}{1 \text{ min}} \right) = \mathbf{4586 \text{ rpm}}$$

Note that for four-stroke cycles, there are two revolutions per cycle.

9-160 Problem 9-159 is reconsidered. The effect of the compression ratio net work done and the efficiency of the cycle is to be investigated. Also, the T - s and P - v diagrams for the cycle are to be plotted.

Analysis Using EES, the problem is solved as follows:

9-161 The compression ratio required for an ideal Otto cycle to produce certain amount of work when consuming a given amount of fuel is to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats. **4** The combustion efficiency is 100 percent.

Properties The properties of air at room temperature are $k = 1.4$ (Table A-2).

Analysis The heat input to the cycle for 0.039 grams of fuel consumption is

$$Q_{\text{in}} = m_{\text{fuel}} q_{\text{HV}} = (0.039 \times 10^{-3} \text{ kg})(43,000 \text{ kJ/kg}) = 1.677 \text{ kJ}$$

The thermal efficiency is then

$$\eta_{\text{th}} = \frac{W_{\text{net}}}{Q_{\text{in}}} = \frac{1 \text{ kJ}}{1.677 \text{ kJ}} = 0.5963$$

From the definition of thermal efficiency, we obtain the required compression ratio to be

$$\eta_{\text{th}} = 1 - \frac{1}{r^{k-1}} \longrightarrow r = \frac{1}{(1 - \eta_{\text{th}})^{1/(k-1)}} = \frac{1}{(1 - 0.5963)^{1/(1.4-1)}} = \mathbf{9.66}$$

9-162E An ideal dual cycle with air as the working fluid with a compression ratio of 12 is considered. The thermal efficiency of the cycle is to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 0.240$ Btu/lbm·R, $c_v = 0.171$ Btu/lbm·R, and $k = 1.4$ (Table A-2E).

Analysis The mass of air is

$$m = \frac{P_1 V_1}{RT_1} = \frac{(14.7 \text{ psia})(98/1728 \text{ ft}^3)}{(0.3704 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(580 \text{ R})} = 0.003881 \text{ lbm}$$

Process 1-2: isentropic compression.

$$T_2 = T_1 \left(\frac{V_1}{V_2} \right)^{k-1} = (580 \text{ R})(14)^{0.4} = 1667 \text{ R}$$

Process 2-x: $v = \text{constant}$ heat addition,

$$Q_{2-x,\text{in}} = m(u_x - u_2) = mc_v(T_x - T_2)$$

$$0.6 \text{ Btu} = (0.003881 \text{ lbm})(0.171 \text{ Btu/lbm} \cdot \text{R})(T_x - 1667) \text{ R} \longrightarrow T_x = 2571 \text{ R}$$

Process x-3: $P = \text{constant}$ heat addition.

$$Q_{x-3,\text{in}} = m(h_3 - h_x) = mc_p(T_3 - T_x)$$

$$1.1 \text{ Btu} = (0.003881 \text{ lbm})(0.240 \text{ Btu/lbm} \cdot \text{R})(T_3 - 2571) \text{ R} \longrightarrow T_3 = 3752 \text{ R}$$

$$\frac{P_3 V_3}{T_3} = \frac{P_x V_x}{T_x} \longrightarrow r_c = \frac{V_3}{V_x} = \frac{T_3}{T_x} = \frac{3752 \text{ R}}{2571 \text{ R}} = 1.459$$

Process 3-4: isentropic expansion.

$$T_4 = T_3 \left(\frac{V_3}{V_4} \right)^{k-1} = T_3 \left(\frac{1.459 V_1}{V_4} \right)^{k-1} = T_3 \left(\frac{1.459}{r} \right)^{k-1} = (3752 \text{ R}) \left(\frac{1.459}{14} \right)^{0.4} = 1519 \text{ R}$$

Process 4-1: $v = \text{constant}$ heat rejection.

$$Q_{\text{out}} = m(u_4 - u_1) = mc_v(T_4 - T_1)$$

$$= (0.003881 \text{ lbm})(0.171 \text{ Btu/lbm} \cdot \text{R})(1519 - 580) \text{ R} = 0.6229 \text{ Btu}$$

$$\eta_{\text{th}} = 1 - \frac{Q_{\text{out}}}{Q_{\text{in}}} = 1 - \frac{0.6229 \text{ Btu}}{1.7 \text{ Btu}} = 0.6336 = \mathbf{63.4\%}$$

9-163 An ideal Stirling cycle with air as the working fluid is considered. The maximum pressure in the cycle and the net work output are to be determined.

Assumptions 1 The air-standard assumptions are applicable. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $R = 0.287$ kJ/kg·K, $c_p = 1.005$ kJ/kg·K, $c_v = 0.718$ kJ/kg·K, and $k = 1.4$ (Table A-2).

Analysis (a) The entropy change during process 1-2 is

$$s_2 - s_1 = \frac{q_{12}}{T_H} = \frac{750 \text{ kJ/kg}}{1800 \text{ K}} = 0.4167 \text{ kJ/kg} \cdot \text{K}$$

and

$$s_2 - s_1 = c_v \ln \frac{T_2}{T_1} + R \ln \frac{v_2}{v_1} \longrightarrow 0.4167 \text{ kJ/kg} \cdot \text{K} = (0.287 \text{ kJ/kg} \cdot \text{K}) \ln \frac{v_2}{v_1} \longrightarrow \frac{v_2}{v_1} = 4.271$$

$$\frac{P_3 v_3}{T_3} = \frac{P_1 v_1}{T_1} \longrightarrow P_1 = P_3 \frac{v_3}{v_1} \frac{T_1}{T_3} = P_3 \frac{v_2}{v_1} \frac{T_1}{T_3} = (200 \text{ kPa}) (4.271) \left(\frac{1800 \text{ K}}{400 \text{ K}} \right) = \mathbf{3844 \text{ kPa}}$$

(b) The net work output is

$$w_{\text{net}} = \eta_{\text{th}} q_{\text{in}} = \left(1 - \frac{T_L}{T_H} \right) q_{\text{in}} = \left(1 - \frac{400 \text{ K}}{1800 \text{ K}} \right) (750 \text{ kJ/kg}) = \mathbf{583 \text{ kJ/kg}}$$

9-164 A simple ideal Brayton cycle with air as the working fluid is considered. The changes in the net work output per unit mass and the thermal efficiency are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with variable specific heats.

Properties The properties of air are given in Table A-17.

Analysis The properties at various states are

$$T_1 = 300 \text{ K} \longrightarrow h_1 = 300.19 \text{ kJ/kg}$$

$$P_{r_1} = 1.386$$

$$T_3 = 1300 \text{ K} \longrightarrow h_3 = 1395.97 \text{ kJ/kg}$$

$$P_{r_3} = 330.9$$

For $r_p = 6$,

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = (6)(1.386) = 8.316 \longrightarrow h_2 = 501.40 \text{ kJ/kg}$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \left(\frac{1}{6}\right)(330.9) = 55.15 \longrightarrow h_4 = 855.3 \text{ kJ/kg}$$

$$q_{\text{in}} = h_3 - h_2 = 1395.97 - 501.40 = 894.57 \text{ kJ/kg}$$

$$q_{\text{out}} = h_4 - h_1 = 855.3 - 300.19 = 555.11 \text{ kJ/kg}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 894.57 - 555.11 = 339.46 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{339.46 \text{ kJ/kg}}{894.57 \text{ kJ/kg}} = 37.9\%$$

For $r_p = 12$,

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = (12)(1.386) = 16.63 \longrightarrow h_2 = 610.6 \text{ kJ/kg}$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \left(\frac{1}{12}\right)(330.9) = 27.58 \longrightarrow h_4 = 704.6 \text{ kJ/kg}$$

$$q_{\text{in}} = h_3 - h_2 = 1395.97 - 610.60 = 785.37 \text{ kJ/kg}$$

$$q_{\text{out}} = h_4 - h_1 = 704.6 - 300.19 = 404.41 \text{ kJ/kg}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 785.37 - 404.41 = 380.96 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{380.96 \text{ kJ/kg}}{785.37 \text{ kJ/kg}} = 48.5\%$$

Thus,

$$(a) \quad \Delta w_{\text{net}} = 380.96 - 339.46 = \mathbf{41.5 \text{ kJ/kg}} \quad (\text{increase})$$

$$(b) \quad \Delta \eta_{\text{th}} = 48.5\% - 37.9\% = \mathbf{10.6\%} \quad (\text{increase})$$

9-165 A simple ideal Brayton cycle with air as the working fluid is considered. The changes in the net work output per unit mass and the thermal efficiency are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, $c_v = 0.718 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$ (Table A-2).

Analysis Processes 1-2 and 3-4 are isentropic. Therefore, For $r_p = 6$,

$$T_2 = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (300 \text{ K})(6)^{0.4/1.4} = 500.6 \text{ K}$$

$$T_4 = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = (1300 \text{ K}) \left(\frac{1}{6} \right)^{0.4/1.4} = 779.1 \text{ K}$$

$$q_{\text{in}} = h_3 - h_2 = c_p (T_3 - T_2) \\ = (1.005 \text{ kJ/kg}\cdot\text{K})(1300 - 500.6)\text{K} = 803.4 \text{ kJ/kg}$$

$$q_{\text{out}} = h_4 - h_1 = c_p (T_4 - T_1) \\ = (1.005 \text{ kJ/kg}\cdot\text{K})(779.1 - 300)\text{K} = 481.5 \text{ kJ/kg}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 803.4 - 481.5 = 321.9 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{321.9 \text{ kJ/kg}}{803.4 \text{ kJ/kg}} = 40.1\%$$

For $r_p = 12$,

$$T_2 = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (300 \text{ K})(12)^{0.4/1.4} = 610.2 \text{ K}$$

$$T_4 = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = (1300 \text{ K}) \left(\frac{1}{12} \right)^{0.4/1.4} = 639.2 \text{ K}$$

$$q_{\text{in}} = h_3 - h_2 = c_p (T_3 - T_2) \\ = (1.005 \text{ kJ/kg}\cdot\text{K})(1300 - 610.2)\text{K} = 693.2 \text{ kJ/kg}$$

$$q_{\text{out}} = h_4 - h_1 = c_p (T_4 - T_1) \\ = (1.005 \text{ kJ/kg}\cdot\text{K})(639.2 - 300)\text{K} = 340.9 \text{ kJ/kg}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 693.2 - 340.9 = 352.3 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{352.3 \text{ kJ/kg}}{693.2 \text{ kJ/kg}} = 50.8\%$$

Thus,

$$(a) \quad \Delta w_{\text{net}} = 352.3 - 321.9 = \mathbf{30.4 \text{ kJ/kg}} \quad (\text{increase})$$

$$(b) \quad \Delta \eta_{\text{th}} = 50.8\% - 40.1\% = \mathbf{10.7\%} \quad (\text{increase})$$

9-166 A regenerative Brayton cycle with helium as the working fluid is considered. The thermal efficiency and the required mass flow rate of helium are to be determined for 100 percent and 80 percent isentropic efficiencies for both the compressor and the turbine.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Helium is an ideal gas with constant specific heats.

Properties The properties of helium are $c_p = 5.1926 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.667$ (Table A-2).

Analysis (a) Assuming $\eta_T = \eta_C = 100\%$,

$$T_{2s} = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (300 \text{ K})(8)^{0.667/1.667} = 689.4 \text{ K}$$

$$T_{4s} = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = (1800 \text{ K}) \left(\frac{1}{8} \right)^{0.667/1.667} = 783.3 \text{ K}$$

$$\varepsilon = \frac{h_5 - h_2}{h_4 - h_2} = \frac{c_p(T_5 - T_2)}{c_p(T_4 - T_2)} \longrightarrow T_5 = T_2 + \varepsilon(T_4 - T_2) = 689.4 + (0.75)(783.3 - 689.4) = 759.8 \text{ K}$$

$$w_{\text{net}} = w_{T,\text{out}} - w_{C,\text{in}} = (h_3 - h_4) - (h_2 - h_1) = c_p [(T_3 - T_4) - (T_2 - T_1)] \\ = (5.1926 \text{ kJ/kg}\cdot\text{K}) [(1800 - 783.3) - (689.4 - 300)] \text{ K} = 3257.3 \text{ kJ/kg}$$

$$\dot{m} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{60,000 \text{ kJ/s}}{3257.3 \text{ kJ/kg}} = \mathbf{18.42 \text{ kg/s}}$$

$$q_{\text{in}} = h_3 - h_5 = c_p(T_3 - T_5) = (5.1926 \text{ kJ/kg}\cdot\text{K})(1800 - 759.8) \text{ K} = 5401.3 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{3257.3 \text{ kJ/kg}}{5401.3 \text{ kJ/kg}} = \mathbf{60.3\%}$$

(b) Assuming $\eta_T = \eta_C = 80\%$,

$$T_{2s} = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (300 \text{ K})(8)^{0.667/1.667} = 689.4 \text{ K}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} = \frac{c_p(T_{2s} - T_1)}{c_p(T_2 - T_1)} \longrightarrow T_2 = T_1 + (T_{2s} - T_1)/\eta_C = 300 + (689.4 - 300)/(0.80) = 786.8 \text{ K}$$

$$T_{4s} = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = (1800 \text{ K}) \left(\frac{1}{8} \right)^{0.667/1.667} = 783.3 \text{ K}$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} = \frac{c_p(T_3 - T_4)}{c_p(T_3 - T_{4s})} \longrightarrow T_4 = T_3 - \eta_T(T_3 - T_{4s}) = 1800 - (0.80)(1800 - 783.3) = 986.6 \text{ K}$$

$$\varepsilon = \frac{h_5 - h_2}{h_4 - h_2} = \frac{c_p(T_5 - T_2)}{c_p(T_4 - T_2)} \longrightarrow T_5 = T_2 + \varepsilon(T_4 - T_2) = 786.8 + (0.75)(986.6 - 786.8) = 936.7 \text{ K}$$

$$w_{\text{net}} = w_{T,\text{out}} - w_{C,\text{in}} = (h_3 - h_4) - (h_2 - h_1) = c_p [(T_3 - T_4) - (T_2 - T_1)] \\ = (5.1926 \text{ kJ/kg}\cdot\text{K}) [(1800 - 986.6) - (786.8 - 300)] \text{ K} = 1695.9 \text{ kJ/kg}$$

$$\dot{m} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{60,000 \text{ kJ/s}}{1695.9 \text{ kJ/kg}} = \mathbf{35.4 \text{ kg/s}}$$

$$q_{\text{in}} = h_3 - h_5 = c_p(T_3 - T_5) = (5.1926 \text{ kJ/kg}\cdot\text{K})(1800 - 936.7) \text{ K} = 4482.8 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{1695.9 \text{ kJ/kg}}{4482.8 \text{ kJ/kg}} = \mathbf{37.8\%}$$

9-167 An ideal gas-turbine cycle with one stage of compression and two stages of expansion and regeneration is considered. The thermal efficiency of the cycle as a function of the compressor pressure ratio and the high-pressure turbine to compressor inlet temperature ratio is to be determined, and to be compared with the efficiency of the standard regenerative cycle.

Analysis The T - s diagram of the cycle is as shown in the figure. If the overall pressure ratio of the cycle is r_p , which is the pressure ratio across the compressor, then the pressure ratio across each turbine stage in the ideal case becomes $\sqrt{r_p}$. Using the isentropic relations, the temperatures at the compressor and turbine exit can be expressed as

$$T_5 = T_2 = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = T_1 (r_p)^{(k-1)/k}$$

$$T_7 = T_4 = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = T_3 \left(\frac{1}{\sqrt{r_p}} \right)^{(k-1)/k} = T_3 r_p^{(1-k)/2k}$$

$$T_6 = T_5 \left(\frac{P_6}{P_5} \right)^{(k-1)/k} = T_5 \left(\frac{1}{\sqrt{r_p}} \right)^{(k-1)/k} = T_2 r_p^{(1-k)/2k} = T_1 r_p^{(k-1)/k} r_p^{(1-k)/2k} = T_1 r_p^{(k-1)/2k}$$

Then,

$$q_{in} = h_3 - h_7 = c_p (T_3 - T_7) = c_p T_3 (1 - r_p^{(1-k)/2k})$$

$$q_{out} = h_6 - h_1 = c_p (T_6 - T_1) = c_p T_1 (r_p^{(k-1)/2k} - 1)$$

and thus

$$\eta_{th} = 1 - \frac{q_{out}}{q_{in}} = 1 - \frac{c_p T_1 (r_p^{(k-1)/2k} - 1)}{c_p T_3 (1 - r_p^{(1-k)/2k})}$$

which simplifies to

$$\eta_{th} = 1 - \frac{T_1}{T_3} r_p^{(k-1)/2k}$$

The thermal efficiency of the single stage ideal regenerative cycle is given as

$$\eta_{th} = 1 - \frac{T_1}{T_3} r_p^{(k-1)/k}$$

Therefore, the regenerative cycle with two stages of expansion has a higher thermal efficiency than the standard regenerative cycle with a single stage of expansion for any given value of the pressure ratio r_p .

9-168 A gas-turbine plant operates on the regenerative Brayton cycle with reheating and intercooling. The back work ratio, the net work output, the thermal efficiency, the second-law efficiency, and the exergies at the exits of the combustion chamber and the regenerator are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with variable specific heats.

Properties The gas constant of air is $R = 0.287 \text{ kJ/kg}\cdot\text{K}$.

Analysis (a) For this problem, we use the properties from EES software. Remember that for an ideal gas, enthalpy is a function of temperature only whereas entropy is functions of both temperature and pressure.

Optimum intercooling and reheating pressure is

$$P_2 = \sqrt{P_1 P_4} = \sqrt{(100)(1200)} = 346.4 \text{ kPa}$$

Process 1-2, 3-4: Compression

$$T_1 = 300 \text{ K} \longrightarrow h_1 = 300.43 \text{ kJ/kg}$$

$$\left. \begin{array}{l} T_1 = 300 \text{ K} \\ P_1 = 100 \text{ kPa} \end{array} \right\} s_1 = 5.7054 \text{ kJ/kg}\cdot\text{K}$$

$$\left. \begin{array}{l} P_2 = 346.4 \text{ kPa} \\ s_2 = s_1 = 5.7054 \text{ kJ/kg}\cdot\text{K} \end{array} \right\} h_{2s} = 428.79 \text{ kJ/kg}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} \longrightarrow 0.80 = \frac{428.79 - 300.43}{h_2 - 300.43} \longrightarrow h_2 = 460.88 \text{ kJ/kg}$$

$$T_3 = 350 \text{ K} \longrightarrow h_3 = 350.78 \text{ kJ/kg}$$

$$\left. \begin{array}{l} T_3 = 350 \text{ K} \\ P_3 = 346.4 \text{ kPa} \end{array} \right\} s_3 = 5.5040 \text{ kJ/kg}\cdot\text{K}$$

$$\left. \begin{array}{l} P_4 = 1200 \text{ kPa} \\ s_4 = s_3 = 5.5040 \text{ kJ/kg}\cdot\text{K} \end{array} \right\} h_{4s} = 500.42 \text{ kJ/kg}$$

$$\eta_C = \frac{h_{4s} - h_3}{h_4 - h_3} \longrightarrow 0.80 = \frac{500.42 - 350.78}{h_4 - 350.78} \longrightarrow h_4 = 537.83 \text{ kJ/kg}$$

Process 6-7, 8-9: Expansion

$$T_6 = 1400 \text{ K} \longrightarrow h_6 = 1514.9 \text{ kJ/kg}$$

$$\left. \begin{array}{l} T_6 = 1400 \text{ K} \\ P_6 = 1200 \text{ kPa} \end{array} \right\} s_6 = 6.6514 \text{ kJ/kg}\cdot\text{K}$$

$$\left. \begin{array}{l} P_7 = 346.4 \text{ kPa} \\ s_7 = s_6 = 6.6514 \text{ kJ/kg}\cdot\text{K} \end{array} \right\} h_{7s} = 1083.9 \text{ kJ/kg}$$

$$\eta_T = \frac{h_6 - h_7}{h_6 - h_{7s}} \longrightarrow 0.80 = \frac{1514.9 - h_7}{1514.9 - 1083.9} \longrightarrow h_7 = 1170.1 \text{ kJ/kg}$$

$$T_8 = 1300 \text{ K} \longrightarrow h_8 = 1395.6 \text{ kJ/kg}$$

$$\left. \begin{array}{l} T_8 = 1300 \text{ K} \\ P_8 = 346.4 \text{ kPa} \end{array} \right\} s_8 = 6.9196 \text{ kJ/kg}\cdot\text{K}$$

$$\left. \begin{array}{l} P_9 = 100 \text{ kPa} \\ s_9 = s_8 = 6.9196 \text{ kJ/kg}\cdot\text{K} \end{array} \right\} h_{9s} = 996.00 \text{ kJ/kg}$$

$$\eta_T = \frac{h_8 - h_9}{h_8 - h_{9s}} \longrightarrow 0.80 = \frac{1395.6 - h_9}{1395.6 - 996.00} \longrightarrow h_9 = 1075.9 \text{ kJ/kg}$$

Cycle analysis:

$$w_{C,\text{in}} = h_2 - h_1 + h_4 - h_3 = 460.88 - 300.43 + 537.83 - 350.78 = 347.50 \text{ kJ/kg}$$

$$w_{T,\text{out}} = h_6 - h_7 + h_8 - h_9 = 1514.9 - 1170.1 + 1395.6 - 1075.9 = 664.50 \text{ kJ/kg}$$

$$r_{\text{bw}} = \frac{w_{C,\text{in}}}{w_{T,\text{out}}} = \frac{347.50}{664.50} = \mathbf{0.523}$$

$$w_{\text{net}} = w_{T,\text{out}} - w_{C,\text{in}} = 664.50 - 347.50 = \mathbf{317.0 \text{ kJ/kg}}$$

Regenerator analysis:

$$\varepsilon_{\text{regen}} = \frac{h_9 - h_{10}}{h_9 - h_4} \longrightarrow 0.75 = \frac{1075.9 - h_{10}}{1075.9 - 537.83} \longrightarrow h_{10} = 672.36 \text{ kJ/kg}$$

$$\left. \begin{array}{l} h_{10} = 672.36 \text{ K} \\ P_{10} = 100 \text{ kPa} \end{array} \right\} s_{10} = 6.5157 \text{ kJ/kg} \cdot \text{K}$$

$$q_{\text{regen}} = h_9 - h_{10} = h_5 - h_4 \longrightarrow 1075.9 - 672.36 = h_5 - 537.83 \longrightarrow h_5 = 941.40 \text{ kJ/kg}$$

$$(b) \quad q_{\text{in}} = h_6 - h_5 = 1514.9 - 941.40 = 573.54 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{317.0}{573.54} = \mathbf{0.553}$$

(c) The second-law efficiency of the cycle is defined as the ratio of actual thermal efficiency to the maximum possible thermal efficiency (Carnot efficiency). The maximum temperature for the cycle can be taken to be the turbine inlet temperature. That is,

$$\eta_{\text{max}} = 1 - \frac{T_1}{T_6} = 1 - \frac{300 \text{ K}}{1400 \text{ K}} = 0.786$$

and

$$\eta_{II} = \frac{\eta_{\text{th}}}{\eta_{\text{max}}} = \frac{0.553}{0.786} = \mathbf{0.704}$$

(d) The exergies at the combustion chamber exit and the regenerator exit are

$$\begin{aligned} x_6 &= h_6 - h_0 - T_0(s_6 - s_0) \\ &= (1514.9 - 300.43) \text{ kJ/kg} - (300 \text{ K})(6.6514 - 5.7054) \text{ kJ/kg} \cdot \text{K} \\ &= \mathbf{930.7 \text{ kJ/kg}} \end{aligned}$$

$$\begin{aligned} x_{10} &= h_{10} - h_0 - T_0(s_{10} - s_0) \\ &= (672.36 - 300.43) \text{ kJ/kg} - (300 \text{ K})(6.5157 - 5.7054) \text{ kJ/kg} \cdot \text{K} \\ &= \mathbf{128.8 \text{ kJ/kg}} \end{aligned}$$

9-169 The thermal efficiency of a two-stage gas turbine with regeneration, reheating and intercooling to that of a three-stage gas turbine is to be compared.

Assumptions 1 The air standard assumptions are applicable. **2** Air is an ideal gas with constant specific heats at room temperature. **3** Kinetic and potential energy changes are negligible.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2a).

Analysis

Two Stages:

The pressure ratio across each stage is

$$r_p = \sqrt{16} = 4$$

The temperatures at the end of compression and expansion are

$$T_c = T_{\min} r_p^{(k-1)/k} = (293 \text{ K})(4)^{0.4/1.4} = 435.4 \text{ K}$$

$$T_e = T_{\max} \left(\frac{1}{r_p} \right)^{(k-1)/k} = (1073 \text{ K}) \left(\frac{1}{4} \right)^{0.4/1.4} = 722.1 \text{ K}$$

The heat input and heat output are

$$q_{\text{in}} = 2c_p(T_{\max} - T_e) = 2(1.005 \text{ kJ/kg}\cdot\text{K})(1073 - 722.1) \text{ K} = 705.4 \text{ kJ/kg}$$

$$q_{\text{out}} = 2c_p(T_c - T_{\min}) = 2(1.005 \text{ kJ/kg}\cdot\text{K})(435.4 - 293) \text{ K} = 286.2 \text{ kJ/kg}$$

The thermal efficiency of the cycle is then

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{286.4}{705.4} = 0.5942 = \mathbf{59.4\%}$$

Three Stages:

The pressure ratio across each stage is

$$r_p = 16^{1/3} = 2.520$$

The temperatures at the end of compression and expansion are

$$T_c = T_{\min} r_p^{(k-1)/k} = (293 \text{ K})(2.520)^{0.4/1.4} = 381.5 \text{ K}$$

$$T_e = T_{\max} \left(\frac{1}{r_p} \right)^{(k-1)/k} = (1073 \text{ K}) \left(\frac{1}{2.520} \right)^{0.4/1.4} = 824.0 \text{ K}$$

The heat input and heat output are

$$q_{\text{in}} = 3c_p(T_{\max} - T_e) = 3(1.005 \text{ kJ/kg}\cdot\text{K})(1073 - 824.0) \text{ K} = 500.5 \text{ kJ/kg}$$

$$q_{\text{out}} = 3c_p(T_c - T_{\min}) = 3(1.005 \text{ kJ/kg}\cdot\text{K})(381.5 - 293) \text{ K} = 178.0 \text{ kJ/kg}$$

The thermal efficiency of the cycle is then

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{178.0}{500.5} = 0.6444 = \mathbf{64.4\%}$$

9-170E A pure jet engine operating on an ideal cycle is considered. The thrust force produced per unit mass flow rate is to be determined.

Assumptions 1 Steady operating conditions exist. **2** The air standard assumptions are applicable. **3** Air is an ideal gas with constant specific heats at room temperature. **4** The turbine work output is equal to the compressor work input.

Properties The properties of air at room temperature are $R = 0.3704 \text{ psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R}$ (Table A-1E), $c_p = 0.24 \text{ Btu}/\text{lbm}\cdot\text{R}$ and $k = 1.4$ (Table A-2Ea).

Analysis (a) We assume the aircraft is stationary and the air is moving towards the aircraft at a velocity of $V_1 = 1200 \text{ ft/s}$. Ideally, the air will leave the diffuser with a negligible velocity ($V_2 \cong 0$).

Diffuser:

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}}^{\phi_0 \text{ (steady)}} \longrightarrow \dot{E}_{\text{in}} = \dot{E}_{\text{out}} \\ h_1 + V_1^2/2 &= h_2 + V_2^2/2 \longrightarrow 0 = h_2 - h_1 + \frac{V_2^2 - V_1^2}{2} \\ 0 &= c_p(T_2 - T_1) - V_1^2/2 \\ T_2 &= T_1 + \frac{V_1^2}{2c_p} = 490 \text{ R} + \frac{(1200 \text{ ft/s})^2}{(2)(0.24 \text{ Btu}/\text{lbm}\cdot\text{R})} \left(\frac{1 \text{ Btu}/\text{lbm}}{25,037 \text{ ft}^2/\text{s}^2} \right) = 609.8 \text{ R} \\ P_2 &= P_1 \left(\frac{T_2}{T_1} \right)^{k/(k-1)} = (10 \text{ psia}) \left(\frac{609.8 \text{ R}}{490 \text{ R}} \right)^{1.4/0.4} = 21.5 \text{ psia} \end{aligned}$$

Compressor:

$$\begin{aligned} P_3 &= P_4 = (r_p)(P_2) = (9)(21.5 \text{ psia}) = 193.5 \text{ psia} \\ T_3 &= T_2 \left(\frac{P_3}{P_2} \right)^{(k-1)/k} = (609.8 \text{ R})(9)^{0.4/1.4} = 1142.4 \text{ R} \end{aligned}$$

Turbine:

$$w_{\text{comp,in}} = w_{\text{turb,out}} \longrightarrow h_3 - h_2 = h_4 - h_5 \longrightarrow c_p(T_3 - T_2) = c_p(T_4 - T_5)$$

$$\text{or } T_5 = T_4 - T_3 + T_2 = 1160 - 1142.4 + 609.8 = 627.4 \text{ R}$$

Nozzle:

$$T_6 = T_4 \left(\frac{P_6}{P_4} \right)^{(k-1)/k} = (1160 \text{ R}) \left(\frac{10 \text{ psia}}{193.5 \text{ psia}} \right)^{0.4/1.4} = 497.5 \text{ R}$$

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}}^{\phi_0 \text{ (steady)}} \longrightarrow \dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$h_5 + V_5^2/2 = h_6 + V_6^2/2$$

$$0 = h_6 - h_5 + \frac{V_6^2 - V_5^2}{2} \longrightarrow 0 = c_p(T_6 - T_5) + V_6^2/2$$

$$\text{or, } V_6 = V_{\text{exit}} = \sqrt{(2)(0.24 \text{ Btu}/\text{lbm}\cdot\text{R})(627.4 - 497.5)\text{R} \left(\frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu}/\text{lbm}} \right)} = 1249 \text{ ft/s}$$

The specific impulse is then

$$\frac{F}{\dot{m}} = V_{\text{exit}} - V_{\text{inlet}} = 1249 - 1200 = \mathbf{49 \text{ m/s}}$$

9-171 The electricity and the process heat requirements of a manufacturing facility are to be met by a cogeneration plant consisting of a gas-turbine and a heat exchanger for steam production. The mass flow rate of the air in the cycle, the back work ratio, the thermal efficiency, the rate at which steam is produced in the heat exchanger, and the utilization efficiency of the cogeneration plant are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with variable specific heats.

Analysis (a) For this problem, we use the properties of air from EES software. Remember that for an ideal gas, enthalpy is a function of temperature only whereas entropy is functions of both temperature and pressure.

Process 1-2: Compression

$$T_1 = 20^\circ\text{C} \longrightarrow h_1 = 293.5 \text{ kJ/kg}$$

$$\left. \begin{array}{l} T_1 = 20^\circ\text{C} \\ P_1 = 100 \text{ kPa} \end{array} \right\} s_1 = 5.682 \text{ kJ/kg} \cdot \text{K}$$

$$\left. \begin{array}{l} P_2 = 1000 \text{ kPa} \\ s_2 = s_1 = 5.682 \text{ kJ/kg} \cdot \text{K} \end{array} \right\} h_{2s} = 567.2 \text{ kJ/kg}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} \longrightarrow 0.86 = \frac{567.2 - 293.5}{h_2 - 293.5} \longrightarrow h_2 = 611.8 \text{ kJ/kg}$$

Process 3-4: Expansion

$$T_4 = 450^\circ\text{C} \longrightarrow h_4 = 738.5 \text{ kJ/kg}$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow 0.88 = \frac{h_3 - 738.5}{h_3 - h_{4s}}$$

We cannot find the enthalpy at state 3 directly. However, using EES, we find

$$h_3 = 1262 \text{ kJ/kg}, T_3 = 913.2^\circ\text{C}, s_3 = 6.507 \text{ kJ/kg} \cdot \text{K}.$$

The solution by hand would require a trial-error approach. Also,

$$T_5 = 325^\circ\text{C} \longrightarrow h_5 = 605.4 \text{ kJ/kg}$$

The inlet water is compressed liquid at 15°C and at the saturation pressure of steam at 200°C (1555 kPa). This is not available in the tables but we can obtain it in EES. The alternative is to use saturated liquid enthalpy at the given temperature.

$$\left. \begin{array}{l} T_{w1} = 15^\circ\text{C} \\ P_1 = 1555 \text{ kPa} \end{array} \right\} h_{w1} = 64.47 \text{ kJ/kg}$$

$$\left. \begin{array}{l} T_{w2} = 200^\circ\text{C} \\ x_2 = 1 \end{array} \right\} h_{w2} = 2792 \text{ kJ/kg}$$

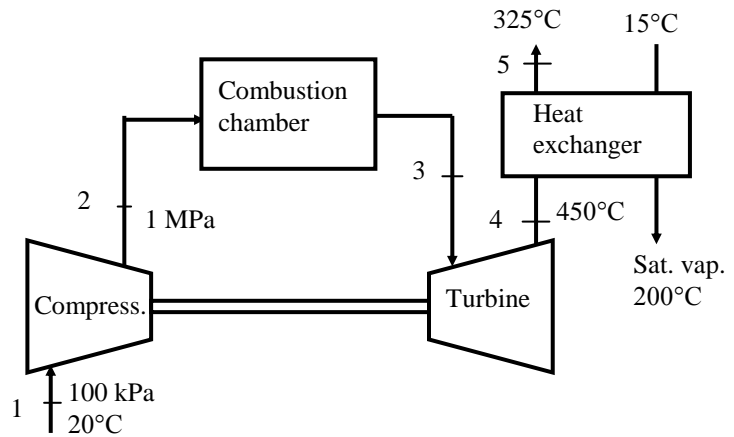

The net work output is

$$w_{C,\text{in}} = h_2 - h_1 = 611.8 - 293.5 = 318.2 \text{ kJ/kg}$$

$$w_{T,\text{out}} = h_3 - h_4 = 1262 - 738.5 = 523.4 \text{ kJ/kg}$$

$$w_{\text{net}} = w_{T,\text{out}} - w_{C,\text{in}} = 523.4 - 318.2 = 205.2 \text{ kJ/kg}$$

The mass flow rate of air is

$$\dot{m}_a = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{1500 \text{ kJ/s}}{205.2 \text{ kJ/kg}} = \mathbf{7.311 \text{ kg/s}}$$

(b) The back work ratio is

$$r_{\text{bw}} = \frac{w_{\text{C,in}}}{w_{\text{T,out}}} = \frac{318.2}{523.4} = \mathbf{0.608}$$

The rate of heat input and the thermal efficiency are

$$\dot{Q}_{\text{in}} = \dot{m}_a (h_3 - h_2) = (7.311 \text{ kg/s})(1262 - 611.8) \text{ kJ/kg} = 4753 \text{ kW}$$

$$\eta_{\text{th}} = \frac{\dot{W}_{\text{net}}}{\dot{Q}_{\text{in}}} = \frac{1500 \text{ kW}}{4753 \text{ kW}} = 0.3156 = \mathbf{31.6\%}$$

(c) An energy balance on the heat exchanger gives

$$\begin{aligned} \dot{m}_a (h_4 - h_5) &= \dot{m}_w (h_{w2} - h_{w1}) \\ (7.311 \text{ kg/s})(738.5 - 605.4) \text{ kJ/kg} &= \dot{m}_w (2792 - 64.47) \text{ kJ/kg} \longrightarrow \dot{m}_w = \mathbf{0.3569 \text{ kg/s}} \end{aligned}$$

(d) The heat supplied to the water in the heat exchanger (process heat) and the utilization efficiency are

$$\dot{Q}_p = \dot{m}_w (h_{w2} - h_{w1}) = (0.3569 \text{ kg/s})(2792 - 64.47) \text{ kJ/kg} = 973.5 \text{ kW}$$

$$\varepsilon_u = \frac{\dot{W}_{\text{net}} + \dot{Q}_p}{\dot{Q}_{\text{in}}} = \frac{1500 + 973.5}{4753 \text{ kW}} = 0.5204 = \mathbf{52.0\%}$$

9-172 A turbojet aircraft flying is considered. The pressure of the gases at the turbine exit, the mass flow rate of the air through the compressor, the velocity of the gases at the nozzle exit, the propulsive power, and the propulsive efficiency of the cycle are to be determined.

Assumptions 1 The air-standard assumptions are applicable. **2** Potential energy changes are negligible. **3** Air is an ideal gas with variable specific heats.

Properties The gas constant of air is $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ (Table A-1).

Analysis (a) For this problem, we use the properties from EES software. Remember that for an ideal gas, enthalpy is a function of temperature only whereas entropy is functions of both temperature and pressure.

Diffuser, Process 1-2:

$$T_1 = -35^\circ\text{C} \longrightarrow h_1 = 238.36 \text{ kJ/kg}$$

$$h_1 + \frac{V_1^2}{2} = h_2 + \frac{V_2^2}{2}$$

$$(238.36 \text{ kJ/kg}) + \frac{(1100/3.6 \text{ m/s})^2}{2} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = h_2 + \frac{(15 \text{ m/s})^2}{2} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) \longrightarrow h_2 = 284.93 \text{ kJ/kg}$$

$$\left. \begin{array}{l} h_2 = 284.93 \text{ kJ/kg} \\ P_2 = 50 \text{ kPa} \end{array} \right\} s_2 = 5.8513 \text{ kJ/kg}\cdot\text{K}$$

Compressor, Process 2-3:

$$\left. \begin{array}{l} P_3 = 450 \text{ kPa} \\ s_3 = s_2 = 5.8513 \text{ kJ/kg}\cdot\text{K} \end{array} \right\} h_{3s} = 534.42 \text{ kJ/kg}$$

$$\eta_C = \frac{h_{3s} - h_2}{h_3 - h_2} \longrightarrow 0.83 = \frac{534.42 - 284.93}{h_3 - 284.93} \longrightarrow h_3 = 585.52 \text{ kJ/kg}$$

Turbine, Process 3-4:

$$T_4 = 950^\circ\text{C} \longrightarrow h_4 = 1305.2 \text{ kJ/kg}$$

$$h_3 - h_2 = h_4 - h_5 \longrightarrow 585.52 - 284.93 = 1305.2 - h_5 \longrightarrow h_5 = 1004.6 \text{ kJ/kg}$$

where the mass flow rates through the compressor and the turbine are assumed equal.

$$\eta_T = \frac{h_4 - h_5}{h_4 - h_{5s}} \longrightarrow 0.83 = \frac{1305.2 - 1004.6}{1305.2 - h_{5s}} \longrightarrow h_{5s} = 943.04 \text{ kJ/kg}$$

$$\left. \begin{array}{l} T_4 = 950^\circ\text{C} \\ P_4 = 450 \text{ kPa} \end{array} \right\} s_4 = 6.7725 \text{ kJ/kg}\cdot\text{K}$$

$$\left. \begin{array}{l} h_{5s} = 943.04 \text{ kJ/kg} \\ s_5 = s_4 = 6.7725 \text{ kJ/kg}\cdot\text{K} \end{array} \right\} P_5 = \mathbf{136.9 \text{ kPa}}$$

(b) The mass flow rate of the air through the compressor is

$$\dot{m} = \frac{\dot{W}_C}{h_3 - h_2} = \frac{800 \text{ kJ/s}}{(585.52 - 284.93) \text{ kJ/kg}} = \mathbf{2.661 \text{ kg/s}}$$

(c) *Nozzle, Process 5-6:*

$$\left. \begin{array}{l} h_5 = 1004.6 \text{ kJ/kg} \\ P_5 = 136.9 \text{ kPa} \end{array} \right\} s_5 = 6.8382 \text{ kJ/kg}\cdot\text{K}$$

$$\left. \begin{aligned} P_6 &= 40 \text{ kPa} \\ s_6 &= s_5 = 6.8382 \text{ kJ/kg}\cdot\text{K} \end{aligned} \right\} h_{6s} = 713.12 \text{ kJ/kg}$$

$$\eta_N = \frac{h_5 - h_6}{h_5 - h_{6s}} \rightarrow 0.83 = \frac{1004.6 - h_6}{1004.6 - 713.12} \rightarrow h_6 = 762.68 \text{ kJ/kg}$$

$$h_5 + \frac{V_5^2}{2} = h_6 + \frac{V_6^2}{2}$$

$$(1004.6 \text{ kJ/kg}) + 0 = 762.68 \text{ kJ/kg} + \frac{V_6^2}{2} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) \rightarrow V_6 = \mathbf{695.6 \text{ m/s}}$$

where the velocity at nozzle inlet is assumed zero.

(d) The propulsive power and the propulsive efficiency are

$$\dot{W}_p = \dot{m}(V_6 - V_1)V_1 = [2.661 \text{ kg/s}](695.6 \text{ m/s} - (1100/3.6) \text{ m/s})[(1100/3.6) \text{ m/s}] \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = \mathbf{317.2 \text{ kW}}$$

$$\dot{Q}_{\text{in}} = \dot{m}(h_4 - h_3) = (2.661 \text{ kg/s})(1305.2 - 585.52) \text{ kJ/kg} = 1915 \text{ kW}$$

$$\eta_p = \frac{\dot{W}_p}{\dot{Q}_{\text{in}}} = \frac{317.2 \text{ kW}}{1915 \text{ kW}} = 0.1656 = \mathbf{16.6\%}$$

$$\eta_P = W_{\text{dot}_P} / Q_{\text{dot}_{in}}$$

9-173 The three processes of an air standard cycle are described. The cycle is to be shown on the P - v and T - s diagrams, and the expressions for back work ratio and the thermal efficiency are to be obtained.

Assumptions 1 The air-standard assumptions are applicable. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with constant specific heats.

Analysis (a) The P - v and T - s diagrams for this cycle are as shown.

(b) The work of expansion is found by the first law for process 2-3:

$$q_{2-3} - w_{2-3} = \Delta u_{2-3}$$

$$q_{2-3} = 0 \text{ (isentropic process)}$$

$$w_{2-3} = -\Delta u_{2-3} = -C_v (T_3 - T_2)$$

$$w_{\text{exp}} = w_{2-3} = C_v (T_2 - T_3)$$

The compression work is found by

$$w_{\text{comp}} = -w_{3-1} = -\int_3^1 P dv = -P(v_1 - v_3) = R(T_3 - T_1)$$

The back work ratio is

$$\frac{w_{\text{comp}}}{w_{\text{exp}}} = \frac{C_v (T_3 - T_1)}{R(T_2 - T_3)} = \frac{C_v T_3 (1 - T_1/T_3)}{R T_3 (T_2/T_3 - 1)} = \frac{C_v (1 - T_1/T_3)}{R (T_2/T_3 - 1)}$$

Process 3-1 is constant pressure; therefore,

$$\frac{P_3 V_3}{T_3} = \frac{P_1 V_1}{T_1} \Rightarrow \frac{T_1}{T_3} = \frac{V_1}{V_3} = \frac{V_2}{V_3} = \frac{1}{r}$$

Process 2-3 is isentropic; therefore,

$$\frac{T_2}{T_3} = \left(\frac{V_2}{V_3} \right)^{k-1} = r^{k-1} \quad \text{and} \quad \frac{P_2}{P_3} = \left(\frac{V_3}{V_2} \right)^k = r^k$$

The back work ratio becomes ($C_v = R/(k-1)$)

$$\frac{w_{\text{comp}}}{w_{\text{exp}}} = (k-1) \frac{1 - \frac{1}{r}}{r^{k-1} - 1} = \frac{k-1}{r} \frac{r-1}{r^{k-1} - 1}$$

(c) Apply first law to the closed system for processes 1-2 and 3-1 to show:

$$q_{\text{in}} = C_v (T_2 - T_1)$$

$$q_{\text{out}} = C_p (T_3 - T_1)$$

The cycle thermal efficiency is given by

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{C_p (T_3 - T_1)}{C_v (T_2 - T_1)} = 1 - k \frac{T_1 (T_3/T_1 - 1)}{T_1 (T_2/T_1 - 1)}$$

Process 1-2 is constant volume; therefore,

$$\frac{P_2 V_2}{T_2} = \frac{P_1 V_1}{T_1} \Rightarrow \frac{T_2}{T_1} = \frac{P_2}{P_1} = \frac{P_2}{P_3} = r^k$$

The efficiency becomes

$$\eta_{th} = 1 - k \frac{r-1}{r^k - 1}$$

(d) Determine the value of the back work ratio and efficiency as r goes to unity.

$$\frac{W_{comp}}{W_{exp}} = (k-1) \frac{1 - \frac{1}{r}}{r^{k-1} - 1} = \frac{k-1}{r} \frac{r-1}{r^{k-1} - 1}$$

$$\lim_{r \rightarrow 1} \frac{W_{comp}}{W_{exp}} = (k-1) \left\{ \lim_{r \rightarrow 1} \frac{r-1}{r^k - r} \right\} = (k-1) \left\{ \lim_{r \rightarrow 1} \frac{1}{kr^{k-1} - 1} \right\}$$

$$\lim_{r \rightarrow 1} \frac{W_{comp}}{W_{exp}} = (k-1) \left\{ \frac{1}{k-1} \right\} = 1$$

$$\eta_{th} = 1 - k \frac{r-1}{r^k - 1}$$

$$\lim_{r \rightarrow 1} \eta_{th} = 1 - k \left\{ \lim_{r \rightarrow 1} \frac{r-1}{r^k - 1} \right\} = 1 - k \left\{ \lim_{r \rightarrow 1} \frac{1}{kr^{k-1}} \right\}$$

$$\lim_{r \rightarrow 1} \eta_{th} = 1 - k \left\{ \frac{1}{k} \right\} = 0$$

These results show that if there is no compression (i.e. $r = 1$), there can be no expansion and no net work will be done even though heat may be added to the system.

9-174 An ideal regenerative Brayton cycle is considered. The pressure ratio that maximizes the thermal efficiency of the cycle is to be determined, and to be compared with the pressure ratio that maximizes the cycle net work.

Analysis Using the isentropic relations, the temperatures at the compressor and turbine exit can be expressed as

$$T_2 = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = T_1 (r_p)^{(k-1)/k}$$

$$T_4 = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = T_3 \left(\frac{1}{r_p} \right)^{(k-1)/k} = T_3 r_p^{-(k-1)/k}$$

Then,

$$q_{\text{in}} = h_3 - h_5 = c_p (T_3 - T_5) = c_p (T_3 - T_4) = c_p T_3 (1 - r_p^{-(k-1)/k})$$

$$q_{\text{out}} = h_6 - h_1 = c_p (T_6 - T_1) = c_p (T_2 - T_1) = c_p T_1 (r_p^{(k-1)/k} - 1)$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = c_p (T_3 - T_3 r_p^{(1-k)/k} - T_1 r_p^{(k-1)/k} + T_1)$$

To maximize the net work, we must have

$$\frac{\partial w_{\text{net}}}{\partial r_p} = c_p \left(-\frac{1-k}{k} T_3 r_p^{(1-k)/k} - 1 - \frac{k-1}{k} T_1 r_p^{(k-1)/k} - 1 \right) = 0$$

Solving for r_p gives

$$r_p = \left(\frac{T_1}{T_3} \right)^{k/2(1-k)}$$

Similarly,

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{c_p T_1 (r_p^{(k-1)/k} - 1)}{c_p T_3 (1 - r_p^{-(k-1)/k})}$$

which simplifies to

$$\eta_{\text{th}} = 1 - \frac{T_1}{T_3} r_p^{(k-1)/k}$$

When $r_p = 1$, the thermal efficiency becomes $\eta_{\text{th}} = 1 - T_1/T_3$, which is the Carnot efficiency. Therefore, the efficiency is a maximum when $r_p = 1$, and must decrease as r_p increases for the fixed values of T_1 and T_3 . Note that the compression ratio cannot be less than 1, and the factor

$$r_p^{(k-1)/k}$$

is always greater than 1 for $r_p > 1$. Also note that the net work $w_{\text{net}} = 0$ for $r_p = 1$. This being the case, the pressure ratio for maximum thermal efficiency, which is $r_p = 1$, is always less than the pressure ratio for maximum work.

9-175 The effect of variable specific heats on the thermal efficiency of the ideal Otto cycle using air as the working fluid is to be investigated. The percentage of error involved in using constant specific heat values at room temperature for different combinations of compression ratio and maximum cycle temperature is to be determined.

Fundamentals of Engineering (FE) Exam Problems

9-184 An Otto cycle with air as the working fluid has a compression ratio of 10.4. Under cold air standard conditions, the thermal efficiency of this cycle is

- (a) 10% (b) 39% (c) 61% (d) 79% (e) 82%

Answer (c) 61%

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

$$r=10.4$$

$$k=1.4$$

$$\text{Eta_Otto}=1-1/r^{(k-1)}$$

"Some Wrong Solutions with Common Mistakes:"

$$W1_Eta = 1/r \text{ "Taking efficiency to be } 1/r\text{"}$$

$$W2_Eta = 1/r^{(k-1)} \text{ "Using incorrect relation"}$$

$$W3_Eta = 1-1/r^{(k1-1)}; k1=1.667 \text{ "Using wrong k value"}$$

9-185 For specified limits for the maximum and minimum temperatures, the ideal cycle with the lowest thermal efficiency is

- (a) Carnot (b) Stirling (c) Ericsson (d) Otto (e) All are the same

Answer (d) Otto

9-186 A Carnot cycle operates between the temperatures limits of 300 K and 2000 K, and produces 600 kW of net power. The rate of entropy change of the working fluid during the heat addition process is

- (a) 0 (b) 0.300 kW/K (c) 0.353 kW/K (d) 0.261 kW/K (e) 2.0 kW/K

Answer (c) 0.353 kW/K

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

$$TL=300 \text{ "K"}$$

$$TH=2000 \text{ "K"}$$

$$W_{net}=600 \text{ "kJ/s"}$$

$$W_{net} = (TH-TL)*DS$$

"Some Wrong Solutions with Common Mistakes:"

$$W1_DS = W_{net}/TH \text{ "Using TH instead of TH-TL"}$$

$$W2_DS = W_{net}/TL \text{ "Using TL instead of TH-TL"}$$

$$W3_DS = W_{net}/(TH+TL) \text{ "Using TH+TL instead of TH-TL"}$$

9-187 Air in an ideal Diesel cycle is compressed from 2 L to 0.13 L, and then it expands during the constant pressure heat addition process to 0.30 L. Under cold air standard conditions, the thermal efficiency of this cycle is

- (a) 41% (b) 59% (c) 66% (d) 70% (e) 78%

Answer (b) 59%

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
V1=2 "L"
V2= 0.13 "L"
V3= 0.30 "L"
r=V1/V2
rc=V3/V2
k=1.4
Eta_Diesel=1-(1/r^(k-1))*(rc^k-1)/k/(rc-1)
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_Eta = 1-(1/r1^(k-1))*(rc^k-1)/k/(rc-1); r1=V1/V3 "Wrong r value"
W2_Eta = 1-Eta_Diesel "Using incorrect relation"
W3_Eta = 1-(1/r^(k1-1))*(rc^k1-1)/k1/(rc-1); k1=1.667 "Using wrong k value"
W4_Eta = 1-1/r^(k-1) "Using Otto cycle efficiency"
```

9-188 Helium gas in an ideal Otto cycle is compressed from 20°C and 2.5 L to 0.25 L, and its temperature increases by an additional 700°C during the heat addition process. The temperature of helium before the expansion process is

- (a) 1790°C (b) 2060°C (c) 1240°C (d) 620°C (e) 820°C

Answer (a) 1790°C

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
k=1.667
V1=2.5
V2=0.25
r=V1/V2
T1=20+273 "K"
T2=T1*r^(k-1)
T3=T2+700-273 "C"
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_T3 = T22+700-273; T22=T1*r^(k1-1); k1=1.4 "Using wrong k value"
W2_T3 = T3+273 "Using K instead of C"
W3_T3 = T1+700-273 "Disregarding temp rise during compression"
W4_T3 = T222+700-273; T222=(T1-273)*r^(k-1) "Using C for T1 instead of K"
```

9-189 In an ideal Otto cycle, air is compressed from 1.20 kg/m³ and 2.2 L to 0.26 L, and the net work output of the cycle is 440 kJ/kg. The mean effective pressure (MEP) for this cycle is

- (a) 612 kPa (b) 599 kPa (c) 528 kPa (d) 416 kPa (e) 367 kPa

Answer (b) 599 kPa

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
rho1=1.20 "kg/m^3"
k=1.4
V1=2.2
V2=0.26
m=rho1*V1/1000 "kg"
w_net=440 "kJ/kg"
Wtotal=m*w_net
MEP=Wtotal/((V1-V2)/1000)
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_MEP = w_net/((V1-V2)/1000) "Disregarding mass"
W2_MEP = Wtotal/(V1/1000) "Using V1 instead of V1-V2"
W3_MEP = (rho1*V2/1000)*w_net/((V1-V2)/1000); "Finding mass using V2 instead of V1"
W4_MEP = Wtotal/((V1+V2)/1000) "Adding V1 and V2 instead of subtracting"
```

9-190 In an ideal Brayton cycle, air is compressed from 95 kPa and 25°C to 1100 kPa. Under cold air standard conditions, the thermal efficiency of this cycle is

- (a) 45% (b) 50% (c) 62% (d) 73% (e) 86%

Answer (b) 50%

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
P1=95 "kPa"
P2=1100 "kPa"
T1=25+273 "K"
rp=P2/P1
k=1.4
Eta_Brayton=1-1/rp^((k-1)/k)

Carnot Vapor Cycle

10-1C The Carnot cycle is not a realistic model for steam power plants because (1) limiting the heat transfer processes to two-phase systems to maintain isothermal conditions severely limits the maximum temperature that can be used in the cycle, (2) the turbine will have to handle steam with a high moisture content which causes erosion, and (3) it is not practical to design a compressor that will handle two phases.

10-2E A steady-flow Carnot engine with water as the working fluid operates at specified conditions. The thermal efficiency, the quality at the end of the heat rejection process, and the net work output are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) We note that

$$T_H = T_{\text{sat}@400 \text{ psia}} = 444.6^\circ\text{F} = 904.6 \text{ R}$$

$$T_L = T_{\text{sat}@20 \text{ psia}} = 227.9^\circ\text{F} = 687.9 \text{ R}$$

and

$$\eta_{\text{th,C}} = 1 - \frac{T_L}{T_H} = 1 - \frac{687.9 \text{ R}}{904.6 \text{ R}} = 0.2395 = \mathbf{24.0\%}$$

(b) Noting that $s_4 = s_1 = s_f @ 400 \text{ psia} = 0.62168 \text{ Btu/lbm}\cdot\text{R}$,

$$x_4 = \frac{s_4 - s_f}{s_{fg}} = \frac{0.62168 - 0.3358}{1.3961} = \mathbf{0.205}$$

(c) The enthalpies before and after the heat addition process are

$$h_1 = h_f @ 400 \text{ psia} = 424.13 \text{ Btu/lbm}$$

$$h_2 = h_f + x_2 h_{fg} = 424.13 + (0.95)(780.87) = 1166.0 \text{ Btu/lbm}$$

Thus,

$$q_{\text{in}} = h_2 - h_1 = 1166.0 - 424.13 = 741.8 \text{ Btu/lbm}$$

and

$$w_{\text{net}} = \eta_{\text{th}} q_{\text{in}} = (0.2395)(741.8 \text{ Btu/lbm}) = \mathbf{178 \text{ Btu/lbm}}$$

10-3 A steady-flow Carnot engine with water as the working fluid operates at specified conditions. The thermal efficiency, the amount of heat rejected, and the net work output are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) Noting that $T_H = 250^\circ\text{C} = 523\text{ K}$ and $T_L = T_{\text{sat}} @ 20\text{ kPa} = 60.06^\circ\text{C} = 333.1\text{ K}$, the thermal efficiency becomes

$$\eta_{\text{th,C}} = 1 - \frac{T_L}{T_H} = 1 - \frac{333.1\text{ K}}{523\text{ K}} = 0.3632 = \mathbf{36.3\%}$$

(b) The heat supplied during this cycle is simply the enthalpy of vaporization,

$$q_{\text{in}} = h_{fg @ 250^\circ\text{C}} = 1715.3\text{ kJ/kg}$$

Thus,

$$q_{\text{out}} = q_L = \frac{T_L}{T_H} q_{\text{in}} = \left(\frac{333.1\text{ K}}{523\text{ K}} \right) (1715.3\text{ kJ/kg}) = \mathbf{1092.3\text{ kJ/kg}}$$

(c) The net work output of this cycle is

$$w_{\text{net}} = \eta_{\text{th}} q_{\text{in}} = (0.3632)(1715.3\text{ kJ/kg}) = \mathbf{623.0\text{ kJ/kg}}$$

10-4 A steady-flow Carnot engine with water as the working fluid operates at specified conditions. The thermal efficiency, the amount of heat rejected, and the net work output are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) Noting that $T_H = 250^\circ\text{C} = 523\text{ K}$ and $T_L = T_{\text{sat}} @ 10\text{ kPa} = 45.81^\circ\text{C} = 318.8\text{ K}$, the thermal efficiency becomes

$$\eta_{\text{th,C}} = 1 - \frac{T_L}{T_H} = 1 - \frac{318.8\text{ K}}{523\text{ K}} = \mathbf{39.04\%}$$

(b) The heat supplied during this cycle is simply the enthalpy of vaporization,

$$q_{\text{in}} = h_{fg @ 250^\circ\text{C}} = 1715.3\text{ kJ/kg}$$

Thus,

$$q_{\text{out}} = q_L = \frac{T_L}{T_H} q_{\text{in}} = \left(\frac{318.8\text{ K}}{523\text{ K}} \right) (1715.3\text{ kJ/kg}) = \mathbf{1045.6\text{ kJ/kg}}$$

(c) The net work output of this cycle is

$$w_{\text{net}} = \eta_{\text{th}} q_{\text{in}} = (0.3904)(1715.3\text{ kJ/kg}) = \mathbf{669.7\text{ kJ/kg}}$$

10-5 A steady-flow Carnot engine with water as the working fluid operates at specified conditions. The thermal efficiency, the pressure at the turbine inlet, and the net work output are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) The thermal efficiency is determined from

$$\eta_{\text{th,C}} = 1 - \frac{T_L}{T_H} = 1 - \frac{60 + 273 \text{ K}}{350 + 273 \text{ K}} = \mathbf{46.5\%}$$

(b) Note that

$$\begin{aligned} s_2 = s_3 &= s_f + x_3 s_{fg} \\ &= 0.8313 + 0.891 \times 7.0769 = 7.1368 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

Thus,

$$\left. \begin{aligned} T_2 &= 350^\circ\text{C} \\ s_2 &= 7.1368 \text{ kJ/kg} \cdot \text{K} \end{aligned} \right\} P_2 \cong \mathbf{1.40 \text{ MPa}} \text{ (Table A-6)}$$

(c) The net work can be determined by calculating the enclosed area on the T - s diagram,

$$s_4 = s_f + x_4 s_{fg} = 0.8313 + (0.1)(7.0769) = 1.5390 \text{ kJ/kg} \cdot \text{K}$$

Thus,

$$w_{\text{net}} = \text{Area} = (T_H - T_L)(s_3 - s_4) = (350 - 60)(7.1368 - 1.5390) = \mathbf{1623 \text{ kJ/kg}}$$

The Simple Rankine Cycle

10-6C Heat rejected decreases; everything else increases.

10-7C Heat rejected decreases; everything else increases.

10-8C The pump work remains the same, the moisture content decreases, everything else increases.

10-9C The actual vapor power cycles differ from the idealized ones in that the actual cycles involve friction and pressure drops in various components and the piping, and heat loss to the surrounding medium from these components and piping.

10-10C We would reject this proposal because $w_{\text{turb}} = h_1 - h_2 - q_{\text{out}}$, and any heat loss from the steam will adversely affect the turbine work output.

10-11C Yes, because the saturation temperature of steam at 10 kPa is 45.81°C, which is much higher than the temperature of the cooling water.

10-12 A steam power plant operates on a simple ideal Rankine cycle between the specified pressure limits. The thermal efficiency of the cycle and the net power output of the plant are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 50 \text{ kPa} = 340.54 \text{ kJ/kg}$$

$$\nu_1 = \nu_f @ 50 \text{ kPa} = 0.001030 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,\text{in}} &= \nu_1 (P_2 - P_1) \\ &= (0.001030 \text{ m}^3/\text{kg})(3000 - 50) \text{ kPa} \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 3.04 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 340.54 + 3.04 = 343.58 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 3 \text{ MPa} \\ T_3 = 300^\circ\text{C} \end{array} \right\} \begin{array}{l} h_3 = 2994.3 \text{ kJ/kg} \\ s_3 = 6.5412 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_4 = 50 \text{ kPa} \\ s_4 = s_3 \end{array} \right\} x_4 = \frac{s_4 - s_f}{s_{fg}} = \frac{6.5412 - 1.0912}{6.5019} = 0.8382$$

$$\begin{aligned} h_4 &= h_f + x_4 h_{fg} = 340.54 + (0.8382)(2304.7) \\ &= 2272.3 \text{ kJ/kg} \end{aligned}$$

Thus,

$$q_{\text{in}} = h_3 - h_2 = 2994.3 - 343.58 = 2650.7 \text{ kJ/kg}$$

$$q_{\text{out}} = h_4 - h_1 = 2272.3 - 340.54 = 1931.8 \text{ kJ/kg}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 2650.7 - 1931.8 = 718.9 \text{ kJ/kg}$$

and

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{1931.8}{2650.7} = \mathbf{27.1\%}$$

$$(b) \quad \dot{W}_{\text{net}} = \dot{m} w_{\text{net}} = (35 \text{ kg/s})(718.9 \text{ kJ/kg}) = \mathbf{25.2 \text{ MW}}$$

10-13 A simple ideal Rankine cycle with R-134a as the working fluid is considered. The turbine inlet temperature, the cycle thermal efficiency, and the back-work ratio of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the refrigerant tables (Tables A-11, A-12, and A-13),

$$P_1 = P_{\text{sat}} @ 24^\circ\text{C} = 646.2 \text{ kPa}$$

$$h_1 = h_f @ 24^\circ\text{C} = 84.98 \text{ kJ/kg}$$

$$v_1 = v_f @ 24^\circ\text{C} = 0.0008260 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{\text{p,in}} &= v_1(P_2 - P_1) \\ &= (0.0008260 \text{ m}^3/\text{kg})(2000 - 646.2) \text{ kPa} \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 1.118 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{\text{p,in}} = 84.98 + 1.118 = 86.09 \text{ kJ/kg}$$

$$\left. \begin{array}{l} T_4 = 24^\circ\text{C} \\ x_4 = 0.93 \end{array} \right\} \begin{array}{l} h_4 = h_f + x_4 h_{fg} = 84.98 + (0.93)(178.74) = 251.21 \text{ kJ/kg} \\ s_4 = s_f + x_4 s_{fg} = 0.31959 + (0.93)(0.60148) = 0.87897 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_3 = 2000 \text{ kPa} \\ s_3 = s_4 = 0.87897 \text{ kJ/kg} \cdot \text{K} \end{array} \right\} \begin{array}{l} h_3 = 272.29 \text{ kJ/kg} \\ T_3 = \mathbf{67.5^\circ\text{C}} \end{array}$$

Thus,

$$q_{\text{in}} = h_3 - h_2 = 272.29 - 86.09 = 186.2 \text{ kJ/kg}$$

$$q_{\text{out}} = h_4 - h_1 = 251.21 - 84.98 = 166.2 \text{ kJ/kg}$$

The thermal efficiency of the cycle is

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{166.2}{186.2} = 0.1072 = \mathbf{10.7\%}$$

The back-work ratio is determined from

$$r_{\text{bw}} = \frac{w_{\text{P,in}}}{W_{\text{T,out}}} = \frac{w_{\text{P,in}}}{h_3 - h_4} = \frac{1.118 \text{ kJ/kg}}{(272.29 - 251.21) \text{ kJ/kg}} = \mathbf{0.0530}$$

10-14 A simple ideal Rankine cycle with water as the working fluid is considered. The work output from the turbine, the heat addition in the boiler, and the thermal efficiency of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the steam tables (Tables A-4, A-5, and A-6),

$$P_1 = P_{\text{sat @ } 40^\circ\text{C}} = 7.385 \text{ kPa}$$

$$P_2 = P_{\text{sat @ } 300^\circ\text{C}} = 8588 \text{ kPa}$$

$$h_1 = h_f @ 40^\circ\text{C} = 167.53 \text{ kJ/kg}$$

$$\nu_1 = \nu_f @ 40^\circ\text{C} = 0.001008 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{\text{p,in}} &= \nu_1 (P_2 - P_1) \\ &= (0.001008 \text{ m}^3/\text{kg})(8588 - 7.385) \text{ kPa} \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 8.65 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{\text{p,in}} = 167.53 + 8.65 = 176.18 \text{ kJ/kg}$$

$$\left. \begin{array}{l} T_3 = 300^\circ\text{C} \\ x_3 = 1 \end{array} \right\} \begin{array}{l} h_3 = 2749.6 \text{ kJ/kg} \\ s_3 = 5.7059 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} T_4 = 40^\circ\text{C} \\ s_4 = s_3 \end{array} \right\} \begin{array}{l} x_4 = \frac{s_4 - s_f}{s_{fg}} = \frac{5.7059 - 0.5724}{7.6832} = 0.6681 \\ h_4 = h_f + x_4 h_{fg} = 167.53 + (0.6681)(2406.0) = 1775.1 \text{ kJ/kg} \end{array}$$

Thus,

$$w_{\text{T,out}} = h_3 - h_4 = 2749.6 - 1775.1 = \mathbf{974.5 \text{ kJ/kg}}$$

$$q_{\text{in}} = h_3 - h_2 = 2749.6 - 176.18 = \mathbf{2573.4 \text{ kJ/kg}}$$

$$q_{\text{out}} = h_4 - h_1 = 1775.1 - 167.53 = 1607.6 \text{ kJ/kg}$$

The thermal efficiency of the cycle is

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{1607.6}{2573.4} = \mathbf{0.375}$$

10-15E A simple ideal Rankine cycle with water as the working fluid operates between the specified pressure limits. The turbine inlet temperature and the thermal efficiency of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the steam tables (Tables A-4E, A-5E, and A-6E),

$$h_1 = h_f @ 5 \text{ psia} = 130.18 \text{ Btu/lbm}$$

$$v_1 = v_f @ 5 \text{ psia} = 0.01641 \text{ ft}^3/\text{lbm}$$

$$\begin{aligned} w_{p,\text{in}} &= v_1 (P_2 - P_1) \\ &= (0.01641 \text{ ft}^3/\text{lbm})(2500 - 5) \text{ psia} \left(\frac{1 \text{ Btu}}{5.404 \text{ psia} \cdot \text{ft}^3} \right) \\ &= 7.58 \text{ Btu/lbm} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 130.18 + 7.58 = 137.76 \text{ Btu/lbm}$$

$$\left. \begin{array}{l} P_4 = 5 \text{ psia} \\ x_4 = 0.80 \end{array} \right\} \begin{array}{l} h_4 = h_f + x_4 h_{fg} = 130.18 + (0.80)(1000.5) = 930.58 \text{ Btu/lbm} \\ s_4 = s_f + x_4 s_{fg} = 0.23488 + (0.80)(1.60894) = 1.52203 \text{ Btu/lbm} \cdot \text{R} \end{array}$$

$$\left. \begin{array}{l} P_3 = 2500 \text{ psia} \\ s_3 = s_4 = 1.52203 \text{ Btu/lbm} \cdot \text{R} \end{array} \right\} \begin{array}{l} h_3 = 1450.8 \text{ Btu/lbm} \\ T_3 = \mathbf{989.2^\circ\text{F}} \end{array}$$

Thus,

$$q_{\text{in}} = h_3 - h_2 = 1450.8 - 137.76 = 1313.0 \text{ Btu/lbm}$$

$$q_{\text{out}} = h_4 - h_1 = 930.58 - 130.18 = 800.4 \text{ Btu/lbm}$$

The thermal efficiency of the cycle is

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{800.4}{1313.0} = \mathbf{0.390}$$

10-16 A steam power plant that operates on a simple ideal Rankine cycle is considered. The quality of the steam at the turbine exit, the thermal efficiency of the cycle, and the mass flow rate of the steam are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 10 \text{ kPa} = 191.81 \text{ kJ/kg}$$

$$\nu_1 = \nu_f @ 10 \text{ kPa} = 0.00101 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,\text{in}} &= \nu_1(P_2 - P_1) \\ &= (0.00101 \text{ m}^3/\text{kg})(10,000 - 10 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 10.09 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 191.81 + 10.09 = 201.90 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 10 \text{ MPa} \\ T_3 = 500 \text{ }^\circ\text{C} \end{array} \right\} \begin{array}{l} h_3 = 3375.1 \text{ kJ/kg} \\ s_3 = 6.5995 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_4 = 10 \text{ kPa} \\ s_4 = s_3 \end{array} \right\} x_4 = \frac{s_4 - s_f}{s_{fg}} = \frac{6.5995 - 0.6492}{7.4996} = \mathbf{0.7934}$$

$$h_4 = h_f + x_4 h_{fg} = 191.81 + (0.7934)(2392.1) = 2089.7 \text{ kJ/kg}$$

$$(b) \quad q_{\text{in}} = h_3 - h_2 = 3375.1 - 201.90 = 3173.2 \text{ kJ/kg}$$

$$q_{\text{out}} = h_4 - h_1 = 2089.7 - 191.81 = 1897.9 \text{ kJ/kg}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 3173.2 - 1897.9 = 1275.4 \text{ kJ/kg}$$

and

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{1275.4 \text{ kJ/kg}}{3173.2 \text{ kJ/kg}} = \mathbf{40.2\%}$$

$$(c) \quad \dot{m} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{210,000 \text{ kJ/s}}{1275.4 \text{ kJ/kg}} = \mathbf{164.7 \text{ kg/s}}$$

10-17 A steam power plant that operates on a simple nonideal Rankine cycle is considered. The quality of the steam at the turbine exit, the thermal efficiency of the cycle, and the mass flow rate of the steam are to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis (a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_{f@10\text{ kPa}} = 191.81 \text{ kJ/kg}$$

$$v_1 = v_{f@10\text{ kPa}} = 0.00101 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,\text{in}} &= v_1(P_2 - P_1)/\eta_p \\ &= (0.00101 \text{ m}^3/\text{kg})(10,000 - 10 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) / (0.85) \\ &= 11.87 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 191.81 + 11.87 = 203.68 \text{ kJ/kg}$$

$$\left. \begin{aligned} P_3 &= 10 \text{ MPa} \\ T_3 &= 500^\circ\text{C} \end{aligned} \right\} \begin{aligned} h_3 &= 3375.1 \text{ kJ/kg} \\ s_3 &= 6.5995 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

$$\left. \begin{aligned} P_{4s} &= 10 \text{ kPa} \\ s_{4s} &= s_3 \end{aligned} \right\} x_{4s} = \frac{s_{4s} - s_f}{s_{fg}} = \frac{6.5995 - 0.6492}{7.4996} = \mathbf{0.7934}$$

$$h_{4s} = h_f + x_{4s}h_{fg} = 191.81 + (0.7934)(2392.1) = 2089.7 \text{ kJ/kg}$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow h_4 = h_3 - \eta_T(h_3 - h_{4s}) = 3375.1 - (0.85)(3375.1 - 2089.7) = 2282.5 \text{ kJ/kg}$$

$$\left. \begin{aligned} P_4 &= 10 \text{ kPa} \\ h_4 &= 2282.5 \text{ kJ/kg} \end{aligned} \right\} x_4 = \frac{h_4 - h_f}{h_{fg}} = \frac{2282.5 - 191.81}{2392.1} = \mathbf{0.874}$$

$$\begin{aligned} (b) \quad q_{\text{in}} &= h_3 - h_2 = 3375.1 - 203.68 = 3171.4 \text{ kJ/kg} \\ q_{\text{out}} &= h_4 - h_1 = 2282.5 - 191.81 = 2090.7 \text{ kJ/kg} \\ w_{\text{net}} &= q_{\text{in}} - q_{\text{out}} = 3171.4 - 2090.7 = 1080.7 \text{ kJ/kg} \end{aligned}$$

and

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{1080.7 \text{ kJ/kg}}{3171.5 \text{ kJ/kg}} = \mathbf{34.1\%}$$

$$(c) \quad \dot{m} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{210,000 \text{ kJ/s}}{1080.7 \text{ kJ/kg}} = \mathbf{194.3 \text{ kg/s}}$$

10-18E A simple steam Rankine cycle operates between the specified pressure limits. The mass flow rate, the power produced by the turbine, the rate of heat addition, and the thermal efficiency of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis From the steam tables (Tables A-4E, A-5E, and A-6E),

$$h_1 = h_f @ 2 \text{ psia} = 94.02 \text{ Btu/lbm}$$

$$v_1 = v_f @ 2 \text{ psia} = 0.016230 \text{ ft}^3/\text{lbm}$$

$$\begin{aligned} w_{p,\text{in}} &= v_1(P_2 - P_1) \\ &= (0.016230 \text{ ft}^3/\text{lbm})(1500 - 2) \text{ psia} \left(\frac{1 \text{ Btu}}{5.404 \text{ psia} \cdot \text{ft}^3} \right) \\ &= 4.50 \text{ Btu/lbm} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 94.02 + 4.50 = 98.52 \text{ Btu/lbm}$$

$$\left. \begin{array}{l} P_3 = 1500 \text{ psia} \\ T_3 = 800^\circ\text{F} \end{array} \right\} \begin{array}{l} h_3 = 1363.1 \text{ Btu/lbm} \\ s_3 = 1.5064 \text{ Btu/lbm} \cdot \text{R} \end{array}$$

$$\left. \begin{array}{l} P_4 = 2 \text{ psia} \\ s_4 = s_3 \end{array} \right\} \begin{array}{l} x_{4s} = \frac{s_4 - s_f}{s_{fg}} = \frac{1.5064 - 0.1750}{1.7444} = 0.7633 \\ h_{4s} = h_f + x_{4s}h_{fg} = 94.02 + (0.7633)(1021.7) = 873.86 \text{ Btu/lbm} \end{array}$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow h_4 = h_3 - \eta_T(h_3 - h_{4s}) = 1363.1 - (0.90)(1363.1 - 873.86) = 922.79 \text{ kJ/kg}$$

Thus,

$$q_{\text{in}} = h_3 - h_2 = 1363.1 - 98.52 = 1264.6 \text{ Btu/lbm}$$

$$q_{\text{out}} = h_4 - h_1 = 922.79 - 94.02 = 828.8 \text{ Btu/lbm}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 1264.6 - 828.8 = 435.8 \text{ Btu/lbm}$$

The mass flow rate of steam in the cycle is determined from

$$\dot{W}_{\text{net}} = \dot{m}w_{\text{net}} \longrightarrow \dot{m} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{2500 \text{ kJ/s}}{435.8 \text{ Btu/lbm}} \left(\frac{0.94782 \text{ Btu}}{1 \text{ kJ}} \right) = \mathbf{5.437 \text{ lbm/s}}$$

The power output from the turbine and the rate of heat addition are

$$\dot{W}_{T,\text{out}} = \dot{m}(h_3 - h_4) = (5.437 \text{ lbm/s})(1363.1 - 922.79) \text{ Btu/lbm} \left(\frac{1 \text{ kJ}}{0.94782 \text{ Btu}} \right) = \mathbf{2526 \text{ kW}}$$

$$\dot{Q}_{\text{in}} = \dot{m}q_{\text{in}} = (5.437 \text{ lbm/s})(1264.6 \text{ Btu/lbm}) = \mathbf{6876 \text{ Btu/s}}$$

and the thermal efficiency of the cycle is

$$\eta_{\text{th}} = \frac{\dot{W}_{\text{net}}}{\dot{Q}_{\text{in}}} = \frac{2500 \text{ kJ/s}}{6876 \text{ Btu/s}} \left(\frac{0.94782 \text{ Btu}}{1 \text{ kJ}} \right) = 0.3446 = \mathbf{34.5\%}$$

10-19E A simple steam Rankine cycle operates between the specified pressure limits. The mass flow rate, the power produced by the turbine, the rate of heat addition, and the thermal efficiency of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis From the steam tables (Tables A-4E, A-5E, and A-6E),

$$h_1 = h_f @ 2 \text{ psia} = 94.02 \text{ Btu/lbm}$$

$$v_1 = v_f @ 2 \text{ psia} = 0.016230 \text{ ft}^3/\text{lbm}$$

$$\begin{aligned} w_{p,\text{in}} &= v_1(P_2 - P_1) \\ &= (0.016230 \text{ ft}^3/\text{lbm})(1500 - 2) \text{ psia} \left(\frac{1 \text{ Btu}}{5.404 \text{ psia} \cdot \text{ft}^3} \right) \\ &= 4.50 \text{ Btu/lbm} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 94.02 + 4.50 = 98.52 \text{ Btu/lbm}$$

$$\left. \begin{array}{l} P_3 = 1500 \text{ psia} \\ T_3 = 800^\circ\text{F} \end{array} \right\} \begin{array}{l} h_3 = 1363.1 \text{ Btu/lbm} \\ s_3 = 1.5064 \text{ Btu/lbm} \cdot \text{R} \end{array}$$

$$\left. \begin{array}{l} P_4 = 2 \text{ psia} \\ s_4 = s_3 \end{array} \right\} \begin{array}{l} x_{4s} = \frac{s_4 - s_f}{s_{fg}} = \frac{1.5064 - 0.1750}{1.7444} = 0.7633 \\ h_{4s} = h_f + x_{4s}h_{fg} = 94.02 + (0.7633)(1021.7) = 873.86 \text{ Btu/lbm} \end{array}$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow h_4 = h_3 - \eta_T(h_3 - h_{4s}) = 1363.1 - (0.90)(1363.1 - 873.86) = 922.79 \text{ kJ/kg}$$

The mass flow rate of steam in the cycle is determined from

$$\dot{W}_{\text{net}} = \dot{m}(h_3 - h_4) \longrightarrow \dot{m} = \frac{\dot{W}_{\text{net}}}{h_3 - h_4} = \frac{2500 \text{ kJ/s}}{(1363.1 - 922.79) \text{ Btu/lbm}} \left(\frac{0.94782 \text{ Btu}}{1 \text{ kJ}} \right) = 5.381 \text{ lbm/s}$$

The rate of heat addition is

$$\dot{Q}_{\text{in}} = \dot{m}(h_3 - h_2) = (5.381 \text{ lbm/s})(1363.1 - 98.52) \text{ Btu/lbm} \left(\frac{1 \text{ kJ}}{0.94782 \text{ Btu}} \right) = 6805 \text{ Btu/s}$$

and the thermal efficiency of the cycle is

$$\eta_{\text{th}} = \frac{\dot{W}_{\text{net}}}{\dot{Q}_{\text{in}}} = \frac{2500 \text{ kJ/s}}{6805 \text{ Btu/s}} \left(\frac{0.94782 \text{ Btu}}{1 \text{ kJ}} \right) = 0.3482$$

The thermal efficiency in the previous problem was determined to be 0.3446. The error in the thermal efficiency caused by neglecting the pump work is then

$$\text{Error} = \frac{0.3482 - 0.3446}{0.3446} \times 100 = \mathbf{1.03\%}$$

10-20E A steam power plant that operates on a simple ideal Rankine cycle between the specified pressure limits is considered. The minimum turbine inlet temperature, the rate of heat input in the boiler, and the thermal efficiency of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) From the steam tables (Tables A-4E, A-5E, and A-6E),

$$h_1 = h_f @ 2 \text{ psia} = 94.02 \text{ Btu/lbm}$$

$$v_1 = v_f @ 2 \text{ psia} = 0.01623 \text{ ft}^3/\text{lbm}$$

$$\begin{aligned} w_{p,\text{in}} &= v_1(P_2 - P_1) \\ &= (0.01623 \text{ ft}^3/\text{lbm})(1250 - 2 \text{ psia}) \left(\frac{1 \text{ Btu}}{5.4039 \text{ psia} \cdot \text{ft}^3} \right) \\ &= 3.75 \text{ Btu/lbm} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 94.02 + 3.75 = 97.77 \text{ Btu/lbm}$$

$$h_4 = h_f + x_4 h_{fg} = 94.02 + (0.9)(1021.7) = 1013.6 \text{ Btu/lbm}$$

$$s_4 = s_f + x_4 s_{fg} = 0.17499 + (0.9)(1.74444) = 1.7450 \text{ Btu/lbm} \cdot \text{R}$$

$$\left. \begin{array}{l} P_3 = 1250 \text{ psia} \\ s_3 = s_4 \end{array} \right\} \begin{array}{l} h_3 = 1693.4 \text{ Btu/lbm} \\ T_3 = 1337^\circ\text{F} \end{array}$$

$$(b) \quad \dot{Q}_{\text{in}} = \dot{m}(h_3 - h_2) = (75 \text{ lbm/s})(1693.4 - 97.77) = \mathbf{119,672 \text{ Btu/s}}$$

$$(c) \quad \dot{Q}_{\text{out}} = \dot{m}(h_4 - h_1) = (75 \text{ lbm/s})(1013.6 - 94.02) = 68,967 \text{ Btu/s}$$

$$\eta_{\text{th}} = 1 - \frac{\dot{Q}_{\text{out}}}{\dot{Q}_{\text{in}}} = 1 - \frac{68,967 \text{ Btu/s}}{119,672 \text{ Btu/s}} = \mathbf{42.4\%}$$

10-21E A steam power plant operates on a simple nonideal Rankine cycle between the specified pressure limits. The minimum turbine inlet temperature, the rate of heat input in the boiler, and the thermal efficiency of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) From the steam tables (Tables A-4E, A-5E, and A-6E),

$$h_1 = h_{f@ 2 \text{ psia}} = 94.02 \text{ Btu/lbm}$$

$$\nu_1 = \nu_{f@ 2 \text{ psia}} = 0.01623 \text{ ft}^3/\text{lbm}$$

$$\begin{aligned} w_{p,\text{in}} &= \nu_1 (P_2 - P_1) / \eta_P \\ &= (0.01623 \text{ ft}^3/\text{lbm})(1250 - 2 \text{ psia}) \left(\frac{1 \text{ Btu}}{5.4039 \text{ psia} \cdot \text{ft}^3} \right) / 0.85 \\ &= 4.41 \text{ Btu/lbm} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 94.02 + 4.41 = 98.43 \text{ Btu/lbm}$$

$$h_4 = h_f + x_4 h_{fg} = 94.02 + (0.9)(1021.7) = 1013.6 \text{ Btu/lbm}$$

$$s_4 = s_f + x_4 s_{fg} = 0.17499 + (0.9)(1.74444) = 1.7450 \text{ Btu/lbm} \cdot \text{R}$$

The turbine inlet temperature is determined by trial and error ,

$$\text{Try 1: } \left. \begin{array}{l} P_3 = 1250 \text{ psia} \\ T_3 = 900^\circ\text{F} \end{array} \right\} \begin{array}{l} h_3 = 1439.0 \text{ Btu/lbm} \\ s_3 = 1.5826 \text{ Btu/lbm} \cdot \text{R} \end{array}$$

$$x_{4s} = \frac{s_{4s} - s_f}{s_{fg}} = \frac{s_3 - s_f}{s_{fg}} = \frac{1.5826 - 0.17499}{1.74444} = 0.8069$$

$$h_{4s} = h_f + x_{4s} h_{fg} = 94.02 + (0.8069)(1021.7) = 918.4 \text{ Btu/lbm}$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} = \frac{1439.0 - 1013.6}{1439.0 - 918.4} = 0.8171$$

$$\text{Try 2: } \left. \begin{array}{l} P_3 = 1250 \text{ psia} \\ T_3 = 1000^\circ\text{F} \end{array} \right\} \begin{array}{l} h_3 = 1498.6 \text{ Btu/lbm} \\ s_3 = 1.6249 \text{ Btu/lbm} \cdot \text{R} \end{array}$$

$$x_{4s} = \frac{s_{4s} - s_f}{s_{fg}} = \frac{s_3 - s_f}{s_{fg}} = \frac{1.6249 - 0.17499}{1.74444} = 0.8312$$

$$h_{4s} = h_f + x_{4s} h_{fg} = 94.02 + (0.8312)(1021.7) = 943.3 \text{ Btu/lbm}$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} = \frac{1498.6 - 1013.6}{1498.6 - 943.3} = 0.8734$$

By linear interpolation, at $\eta_T = 0.85$ we obtain $T_3 = 958.4^\circ\text{F}$. This is approximate. We can determine state 3 exactly using EES software with these results: $T_3 = \mathbf{955.7^\circ\text{F}}$, $h_3 = 1472.5 \text{ Btu/lbm}$.

$$(b) \quad \dot{Q}_{\text{in}} = \dot{m}(h_3 - h_2) = (75 \text{ lbm/s})(1472.5 - 98.43) = \mathbf{103,055 \text{ Btu/s}}$$

$$(c) \quad \dot{Q}_{\text{out}} = \dot{m}(h_4 - h_1) = (75 \text{ lbm/s})(1013.6 - 94.02) = 68,969 \text{ Btu/s}$$

$$\eta_{\text{th}} = 1 - \frac{\dot{Q}_{\text{out}}}{\dot{Q}_{\text{in}}} = 1 - \frac{68,969 \text{ Btu/s}}{103,055 \text{ Btu/s}} = \mathbf{33.1\%}$$

10-22 A simple Rankine cycle with water as the working fluid operates between the specified pressure limits. The rate of heat addition in the boiler, the power input to the pumps, the net power, and the thermal efficiency of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the steam tables (Tables A-4, A-5, and A-6),

$$\left. \begin{aligned} P_1 &= 50 \text{ kPa} \\ T_1 &= T_{\text{sat @ 50 kPa}} - 6.3 = 81.3 - 6.3 = 75^\circ\text{C} \end{aligned} \right\} \begin{aligned} h_1 &\cong h_f @ 75^\circ\text{C} = 314.03 \text{ kJ/kg} \\ \nu_1 &= \nu_f @ 75^\circ\text{C} = 0.001026 \text{ m}^3/\text{kg} \end{aligned}$$

$$\begin{aligned} w_{\text{p,in}} &= \nu_1 (P_2 - P_1) \\ &= (0.001026 \text{ m}^3/\text{kg})(6000 - 50) \text{ kPa} \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 6.10 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{\text{p,in}} = 314.03 + 6.10 = 320.13 \text{ kJ/kg}$$

$$\left. \begin{aligned} P_3 &= 6000 \text{ kPa} \\ T_3 &= 450^\circ\text{C} \end{aligned} \right\} \begin{aligned} h_3 &= 3302.9 \text{ kJ/kg} \\ s_3 &= 6.7219 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

$$\left. \begin{aligned} P_4 &= 50 \text{ kPa} \\ s_4 &= s_3 \end{aligned} \right\} \begin{aligned} x_{4s} &= \frac{s_4 - s_f}{s_{fg}} = \frac{6.7219 - 1.0912}{6.5019} = 0.8660 \\ h_{4s} &= h_f + x_{4s} h_{fg} = 340.54 + (0.8660)(2304.7) = 2336.4 \text{ kJ/kg} \end{aligned}$$

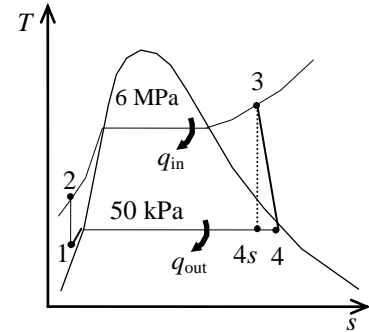

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow h_4 = h_3 - \eta_T (h_3 - h_{4s}) = 3302.9 - (0.94)(3302.9 - 2336.4) = 2394.4 \text{ kJ/kg}$$

Thus,

$$\begin{aligned} \dot{Q}_{\text{in}} &= \dot{m}(h_3 - h_2) = (20 \text{ kg/s})(3302.9 - 320.13) \text{ kJ/kg} = \mathbf{59,660 \text{ kW}} \\ \dot{W}_{\text{T,out}} &= \dot{m}(h_3 - h_4) = (20 \text{ kg/s})(3302.9 - 2394.4) \text{ kJ/kg} = 18,170 \text{ kW} \\ \dot{W}_{\text{P,in}} &= \dot{m} w_{\text{P,in}} = (20 \text{ kg/s})(6.10 \text{ kJ/kg}) = \mathbf{122 \text{ kW}} \\ \dot{W}_{\text{net}} &= \dot{W}_{\text{T,out}} - \dot{W}_{\text{P,in}} = 18,170 - 122 = \mathbf{18,050 \text{ kW}} \end{aligned}$$

and

$$\eta_{\text{th}} = \frac{\dot{W}_{\text{net}}}{\dot{Q}_{\text{in}}} = \frac{18,050}{59,660} = \mathbf{0.3025}$$

10-23 The change in the thermal efficiency of the cycle in Prob. 10-22 due to a pressure drop in the boiler is to be determined.

Analysis We use the following EES routine to obtain the solution.

"Given"

```
P[2]=6000 [kPa]

Discussion The thermal efficiency without a pressure drop was obtained to be 0.3025.

10-24 The net work outputs and the thermal efficiencies for a Carnot cycle and a simple ideal Rankine cycle are to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis (a) Rankine cycle analysis: From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 50 \text{ kPa} = 340.54 \text{ kJ/kg}$$

$$v_1 = v_f @ 50 \text{ kPa} = 0.001030 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,\text{in}} &= v_1(P_2 - P_1) \\ &= (0.001030 \text{ m}^3/\text{kg})(5000 - 50) \text{ kPa} \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 5.10 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 340.54 + 5.10 = 345.64 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 5 \text{ MPa} \\ x_3 = 1 \end{array} \right\} \begin{array}{l} h_3 = 2794.2 \text{ kJ/kg} \\ s_3 = 5.9737 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_4 = 50 \text{ kPa} \\ s_4 = s_3 \end{array} \right\} x_4 = \frac{s_4 - s_f}{s_{fg}} = \frac{5.9737 - 1.09120}{6.5019} = 0.7509$$

$$\begin{aligned} h_4 &= h_f + x_4 h_{fg} = 340.54 + (0.7509)(2304.7) \\ &= 2071.2 \text{ kJ/kg} \end{aligned}$$

$$q_{\text{in}} = h_3 - h_2 = 2794.2 - 345.64 = 2448.6 \text{ kJ/kg}$$

$$q_{\text{out}} = h_4 - h_1 = 2071.2 - 340.54 = 1730.7 \text{ kJ/kg}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 2448.6 - 1730.7 = \mathbf{717.9 \text{ kJ/kg}}$$

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{1730.7}{2448.6} = 0.2932 = \mathbf{29.3\%}$$

(b) Carnot Cycle analysis:

$$\left. \begin{array}{l} P_3 = 5 \text{ MPa} \\ x_3 = 1 \end{array} \right\} \begin{array}{l} h_3 = 2794.2 \text{ kJ/kg} \\ T_3 = 263.9^\circ\text{C} \end{array}$$

$$\left. \begin{array}{l} T_2 = T_3 = 263.9^\circ\text{C} \\ x_2 = 0 \end{array} \right\} \begin{array}{l} h_2 = 1154.5 \text{ kJ/kg} \\ s_2 = 2.9207 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_1 = 50 \text{ kPa} \\ s_1 = s_2 \end{array} \right\} x_1 = \frac{s_1 - s_f}{s_{fg}} = \frac{2.9207 - 1.0912}{6.5019} = 0.2814$$

$$\begin{aligned} h_1 &= h_f + x_1 h_{fg} \\ &= 340.54 + (0.2814)(2304.7) = 989.05 \text{ kJ/kg} \end{aligned}$$

$$q_{\text{in}} = h_3 - h_2 = 2794.2 - 1154.5 = 1639.7 \text{ kJ/kg}$$

$$q_{\text{out}} = h_4 - h_1 = 2071.2 - 340.54 = 1082.2 \text{ kJ/kg}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 1639.7 - 1082.2 = \mathbf{557.5 \text{ kJ/kg}}$$

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{1082.2}{1639.7} = 0.3400 = \mathbf{34.0\%}$$

10-25 A binary geothermal power operates on the simple Rankine cycle with isobutane as the working fluid. The isentropic efficiency of the turbine, the net power output, and the thermal efficiency of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Properties The specific heat of geothermal water is taken to be 4.18 kJ/kg·°C.

Analysis (a) We need properties of isobutane, which are not available in the book. However, we can obtain the properties from EES.

Turbine:

$$\left. \begin{array}{l} P_3 = 3250 \text{ kPa} \\ T_3 = 147^\circ\text{C} \end{array} \right\} \begin{array}{l} h_3 = 761.54 \text{ kJ/kg} \\ s_3 = 2.5457 \text{ kJ/kg}\cdot\text{K} \end{array}$$

$$\left. \begin{array}{l} P_4 = 410 \text{ kPa} \\ s_4 = s_3 \end{array} \right\} h_{4s} = 670.40 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_4 = 410 \text{ kPa} \\ T_4 = 179.5^\circ\text{C} \end{array} \right\} h_4 = 689.74 \text{ kJ/kg}$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} = \frac{761.54 - 689.74}{761.54 - 670.40} = \mathbf{0.788}$$

(b) Pump:

$$h_1 = h_f @ 410 \text{ kPa} = 273.01 \text{ kJ/kg}$$

$$v_1 = v_f @ 410 \text{ kPa} = 0.001842 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,\text{in}} &= v_1(P_2 - P_1)/\eta_P \\ &= (0.001842 \text{ m}^3/\text{kg})(3250 - 410) \text{ kPa} \left(\frac{1 \text{ kJ}}{1 \text{ kPa}\cdot\text{m}^3} \right) / 0.90 \\ &= 5.81 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 273.01 + 5.81 = 278.82 \text{ kJ/kg}$$

$$\dot{W}_{T,\text{out}} = \dot{m}(h_3 - h_4) = (305.6 \text{ kJ/kg})(761.54 - 689.74) \text{ kJ/kg} = 21,941 \text{ kW}$$

$$\dot{W}_{P,\text{in}} = \dot{m}(h_2 - h_1) = \dot{m}w_{p,\text{in}} = (305.6 \text{ kJ/kg})(5.81 \text{ kJ/kg}) = 1777 \text{ kW}$$

$$\dot{W}_{\text{net}} = \dot{W}_{T,\text{out}} - \dot{W}_{P,\text{in}} = 21,941 - 1777 = \mathbf{20,165 \text{ kW}}$$

Heat Exchanger:

$$\dot{Q}_{\text{in}} = \dot{m}_{\text{geo}} c_{\text{geo}}(T_{\text{in}} - T_{\text{out}}) = (555.9 \text{ kJ/kg})(4.18 \text{ kJ/kg}\cdot^\circ\text{C})(160 - 90)^\circ\text{C} = 162,656 \text{ kW}$$

$$(c) \quad \eta_{\text{th}} = \frac{\dot{W}_{\text{net}}}{\dot{Q}_{\text{in}}} = \frac{20,165}{162,656} = \mathbf{0.124 = 12.4\%}$$

10-26 A 175-MW coal-fired steam power plant operates on a simple ideal Rankine cycle between the specified pressure limits. The overall plant efficiency and the required rate of the coal supply are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 15 \text{ kPa} = 225.94 \text{ kJ/kg}$$

$$v_1 = v_f @ 15 \text{ kPa} = 0.0010140 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,\text{in}} &= v_1(P_2 - P_1) \\ &= (0.001014 \text{ m}^3/\text{kg})(7000 - 15 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 7.08 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 225.94 + 7.08 = 233.03 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 7 \text{ MPa} \\ T_3 = 550^\circ\text{C} \end{array} \right\} \begin{array}{l} h_3 = 3531.6 \text{ kJ/kg} \\ s_3 = 6.9507 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_4 = 15 \text{ kPa} \\ s_4 = s_3 \end{array} \right\} x_4 = \frac{s_4 - s_f}{s_{fg}} = \frac{6.9507 - 0.7549}{7.2522} = 0.8543$$

$$h_4 = h_f + x_4 h_{fg} = 225.94 + (0.8543)(2372.4) = 2252.7 \text{ kJ/kg}$$

The thermal efficiency is determined from

$$q_{\text{in}} = h_3 - h_2 = 3531.6 - 233.03 = 3298.6 \text{ kJ/kg}$$

$$q_{\text{out}} = h_4 - h_1 = 2252.7 - 225.94 = 2026.8 \text{ kJ/kg}$$

and

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{2026.8}{3298.6} = 0.3856$$

Thus,

$$\eta_{\text{overall}} = \eta_{\text{th}} \times \eta_{\text{comb}} \times \eta_{\text{gen}} = (0.3856)(0.85)(0.96) = 0.3146 = \mathbf{31.5\%}$$

(b) Then the required rate of coal supply becomes

$$\dot{Q}_{\text{in}} = \frac{\dot{W}_{\text{net}}}{\eta_{\text{overall}}} = \frac{175,000 \text{ kJ/s}}{0.3146} = 556,220 \text{ kJ/s}$$

and

$$\dot{m}_{\text{coal}} = \frac{\dot{Q}_{\text{in}}}{\text{HV}_{\text{coal}}} = \frac{556,220 \text{ kJ/s}}{29,300 \text{ kJ/kg}} = 18.98 \text{ kg/s} = \mathbf{68.3 \text{ tons/h}}$$

The Reheat Rankine Cycle

10-27C The T - s diagram of the ideal Rankine cycle with 3 stages of reheat is shown on the side. The cycle efficiency will increase as the number of reheating stages increases.

10-28C The pump work remains the same, the moisture content decreases, everything else increases.

10-29C The thermal efficiency of the simple ideal Rankine cycle will probably be higher since the average temperature at which heat is added will be higher in this case.

10-30 An ideal reheat steam Rankine cycle produces 2000 kW power. The mass flow rate of the steam, the rate of heat transfer in the reheater, the power used by the pumps, and the thermal efficiency of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the steam tables (Tables A-4, A-5, and A-6 or EES),

$$h_1 = h_f @ 100 \text{ kPa} = 417.51 \text{ kJ/kg}$$

$$v_1 = v_f @ 100 \text{ kPa} = 0.001043 \text{ m}^3/\text{kg}$$

$$w_{p,\text{in}} = v_1 (P_2 - P_1) \\ = (0.001043 \text{ m}^3/\text{kg})(15000 - 100) \text{ kPa} \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ = 15.54 \text{ kJ/kg}$$

$$h_2 = h_1 + w_{p,\text{in}} = 417.51 + 15.54 = 433.05 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 15,000 \text{ kPa} \\ T_3 = 450^\circ\text{C} \end{array} \right\} \begin{array}{l} h_3 = 3157.9 \text{ kJ/kg} \\ s_3 = 6.1434 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_4 = 2000 \text{ kPa} \\ s_4 = s_3 \end{array} \right\} \begin{array}{l} x_4 = \frac{s_4 - s_f}{s_{fg}} = \frac{6.1434 - 2.4467}{3.8923} = 0.9497 \\ h_4 = h_f + x_4 h_{fg} = 908.47 + (0.9497)(1889.8) = 2703.3 \text{ kJ/kg} \end{array}$$

$$\left. \begin{array}{l} P_5 = 2000 \text{ kPa} \\ T_5 = 450^\circ\text{C} \end{array} \right\} \begin{array}{l} h_5 = 3358.2 \text{ kJ/kg} \\ s_5 = 7.2866 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_6 = 100 \text{ kPa} \\ s_6 = s_5 \end{array} \right\} \begin{array}{l} x_6 = \frac{s_6 - s_f}{s_{fg}} = \frac{7.2866 - 1.3028}{6.0562} = 0.9880 \\ h_6 = h_f + x_6 h_{fg} = 417.51 + (0.9880)(22257.5) = 2648.0 \text{ kJ/kg} \end{array}$$

Thus,

$$q_{\text{in}} = (h_3 - h_2) + (h_5 - h_4) = 3157.9 - 433.05 + 3358.2 - 2703.3 = 3379.8 \text{ kJ/kg}$$

$$q_{\text{out}} = h_6 - h_1 = 2648.0 - 417.51 = 2230.5 \text{ kJ/kg}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 3379.8 - 2230.5 = 1149.2 \text{ kJ/kg}$$

The power produced by the cycle is

$$\dot{W}_{\text{net}} = \dot{m} w_{\text{net}} = (1.74 \text{ kg/s})(1149.2 \text{ kJ/kg}) = \mathbf{2000 \text{ kW}}$$

The rate of heat transfer in the reheater is

$$\dot{Q}_{\text{reheater}} = \dot{m}(h_5 - h_4) = (1.740 \text{ kg/s})(3358.2 - 2703.3) \text{ kJ/kg} = \mathbf{1140 \text{ kW}}$$

$$\dot{W}_{P,\text{in}} = \dot{m} w_{P,\text{in}} = (1.740 \text{ kg/s})(15.54 \text{ kJ/kg}) = \mathbf{27 \text{ kW}}$$

and the thermal efficiency of the cycle is

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{2230.5}{3379.8} = \mathbf{0.340}$$

10-31 A steam power plant that operates on the ideal reheat Rankine cycle is considered. The turbine work output and the thermal efficiency of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 20 \text{ kPa} = 251.42 \text{ kJ/kg}$$

$$v_1 = v_f @ 20 \text{ kPa} = 0.001017 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,\text{in}} &= v_1 (P_2 - P_1) \\ &= (0.001017 \text{ m}^3/\text{kg})(6000 - 20 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 6.08 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 251.42 + 6.08 = 257.50 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 6 \text{ MPa} \\ T_3 = 400^\circ\text{C} \end{array} \right\} \begin{array}{l} h_3 = 3178.3 \text{ kJ/kg} \\ s_3 = 6.5432 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_4 = 2 \text{ MPa} \\ s_4 = s_3 \end{array} \right\} h_4 = 2901.0 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_5 = 2 \text{ MPa} \\ T_5 = 400^\circ\text{C} \end{array} \right\} \begin{array}{l} h_5 = 3248.4 \text{ kJ/kg} \\ s_5 = 7.1292 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_6 = 20 \text{ kPa} \\ s_6 = s_5 \end{array} \right\} \begin{array}{l} x_6 = \frac{s_6 - s_f}{s_{fg}} = \frac{7.1292 - 0.8320}{7.0752} = 0.8900 \\ h_6 = h_f + x_6 h_{fg} = 251.42 + (0.8900)(2357.5) = 2349.7 \text{ kJ/kg} \end{array}$$

The turbine work output and the thermal efficiency are determined from

$$w_{T,\text{out}} = (h_3 - h_4) + (h_5 - h_6) = 3178.3 - 2901.0 + 3248.4 - 2349.7 = \mathbf{1176 \text{ kJ/kg}}$$

and

$$q_{\text{in}} = (h_3 - h_2) + (h_5 - h_4) = 3178.3 - 257.50 + 3248.4 - 2901.0 = 3268 \text{ kJ/kg}$$

$$w_{\text{net}} = w_{T,\text{out}} - w_{p,\text{in}} = 1176 - 6.08 = 1170 \text{ kJ/kg}$$

Thus,

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{1170 \text{ kJ/kg}}{3268 \text{ kJ/kg}} = 0.358 = \mathbf{35.8\%}$$

10-32 Problem 10-31 is reconsidered. The problem is to be solved by the diagram window data entry feature of EES by including the effects of the turbine and pump efficiencies and reheat on the steam quality at the low-pressure turbine exit. Also, the T - s diagram is to be plotted.

Analysis The problem is solved using EES, and the solution is given below.

10-33E A steam power plant that operates on the ideal reheat Rankine cycle is considered. The pressure at which reheating takes place, the net power output, the thermal efficiency, and the minimum mass flow rate of the cooling water required are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) From the steam tables (Tables A-4E, A-5E, and A-6E),

$$\begin{aligned}
 h_1 &= h_{\text{sat}@ 1 \text{ psia}} = 69.72 \text{ Btu/lbm} \\
 v_1 &= v_{\text{sat}@ 1 \text{ psia}} = 0.01614 \text{ ft}^3/\text{lbm} \\
 T_1 &= T_{\text{sat}@ 1 \text{ psia}} = 101.69^\circ\text{F} \\
 w_{p,\text{in}} &= v_1(P_2 - P_1) \\
 &= (0.01614 \text{ ft}^3/\text{lbm})(800 - 1 \text{ psia}) \left(\frac{1 \text{ Btu}}{5.4039 \text{ psia} \cdot \text{ft}^3} \right) \\
 &= 2.39 \text{ Btu/lbm} \\
 h_2 &= h_1 + w_{p,\text{in}} = 69.72 + 2.39 = 72.11 \text{ Btu/lbm} \\
 P_3 = 800 \text{ psia} & \left. \begin{array}{l} h_3 = 1456.0 \text{ Btu/lbm} \\ T_3 = 900^\circ\text{F} \end{array} \right\} s_3 = 1.6413 \text{ Btu/lbm} \cdot \text{R} \\
 s_4 = s_3 & \left. \begin{array}{l} h_4 = h_g@ s_g = s_4 = 1178.5 \text{ Btu/lbm} \\ (\text{sat. vapor}) \left. \begin{array}{l} P_4 = P_{\text{sat}@ s_g = s_4} = \mathbf{62.23 \text{ psia}} \text{ (thereheat pressure)} \end{array} \right\} \end{array} \right. \\
 P_5 = 62.23 \text{ psia} & \left. \begin{array}{l} h_5 = 1431.4 \text{ Btu/lbm} \\ T_5 = 800^\circ\text{F} \end{array} \right\} s_5 = 1.8985 \text{ Btu/lbm} \cdot \text{R} \\
 P_6 = 1 \text{ psia} & \left. \begin{array}{l} x_6 = \frac{s_6 - s_f}{s_{fg}} = \frac{1.8985 - 0.13262}{1.84495} = 0.9572 \\ s_6 = s_5 \end{array} \right\} h_6 = h_f + x_6 h_{fg} = 69.72 + (0.9572)(1035.7) = 1061.0 \text{ Btu/lbm}
 \end{aligned}$$

$$(b) \quad q_{\text{in}} = (h_3 - h_2) + (h_5 - h_4) = 1456.0 - 72.11 + 1431.4 - 1178.5 = 1636.8 \text{ Btu/lbm}$$

$$q_{\text{out}} = h_6 - h_1 = 1061.0 - 69.72 = 991.3 \text{ Btu/lbm}$$

Thus,

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{991.3 \text{ Btu/lbm}}{1636.8 \text{ Btu/lbm}} = \mathbf{39.4\%}$$

(c) The mass flow rate of the cooling water will be minimum when it is heated to the temperature of the steam in the condenser, which is 101.7°F ,

$$\begin{aligned}
 \dot{Q}_{\text{out}} &= \dot{Q}_{\text{in}} - \dot{W}_{\text{net}} = (1 - \eta_{\text{th}}) \dot{Q}_{\text{in}} = (1 - 0.3943)(6 \times 10^4 \text{ Btu/s}) = 3.634 \times 10^4 \text{ Btu/s} \\
 \dot{m}_{\text{cool}} &= \frac{\dot{Q}_{\text{out}}}{c \Delta T} = \frac{3.634 \times 10^4 \text{ Btu/s}}{(1.0 \text{ Btu/lbm} \cdot ^\circ\text{F})(101.69 - 45)^\circ\text{F}} = \mathbf{641.0 \text{ lbm/s}}
 \end{aligned}$$

10-34 An ideal reheat Rankine with water as the working fluid is considered. The temperatures at the inlet of both turbines, and the thermal efficiency of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 20 \text{ kPa} = 251.42 \text{ kJ/kg}$$

$$v_1 = v_f @ 20 \text{ kPa} = 0.0010172 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,\text{in}} &= v_1(P_2 - P_1) \\ &= (0.0010172 \text{ m}^3/\text{kg})(5000 - 20) \text{ kPa} \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 5.065 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 251.42 + 5.065 = 256.49 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_4 = 1200 \text{ kPa} \\ x_4 = 0.96 \end{array} \right\} \begin{array}{l} h_4 = h_f + x_4 h_{fg} = 798.33 + (0.96)(1985.4) = 2704.3 \text{ kJ/kg} \\ s_4 = s_f + x_4 s_{fg} = 2.2159 + (0.96)(4.3058) = 6.3495 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_3 = 5000 \text{ kPa} \\ s_3 = s_4 \end{array} \right\} \begin{array}{l} h_3 = 3006.9 \text{ kJ/kg} \\ T_3 = \mathbf{327.2^\circ\text{C}} \end{array}$$

$$\left. \begin{array}{l} P_6 = 20 \text{ kPa} \\ x_6 = 0.96 \end{array} \right\} \begin{array}{l} h_6 = h_f + x_6 h_{fg} = 251.42 + (0.96)(2357.5) = 2514.6 \text{ kJ/kg} \\ s_6 = s_f + x_6 s_{fg} = 0.8320 + (0.96)(7.0752) = 7.6242 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_5 = 1200 \text{ kPa} \\ s_5 = s_6 \end{array} \right\} \begin{array}{l} h_5 = 3436.0 \text{ kJ/kg} \\ T_5 = \mathbf{481.1^\circ\text{C}} \end{array}$$

Thus,

$$q_{\text{in}} = (h_3 - h_2) + (h_5 - h_4) = 3006.9 - 256.49 + 3436.0 - 2704.3 = 3482.0 \text{ kJ/kg}$$

$$q_{\text{out}} = h_6 - h_1 = 2514.6 - 251.42 = 2263.2 \text{ kJ/kg}$$

and

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{2263.2}{3482.0} = 0.3500 = \mathbf{35.0\%}$$

10-35 A steam power plant that operates on an ideal reheat Rankine cycle between the specified pressure limits is considered. The pressure at which reheating takes place, the total rate of heat input in the boiler, and the thermal efficiency of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_{\text{sat}@ 10 \text{ kPa}} = 191.81 \text{ kJ/kg}$$

$$v_1 = v_{\text{sat}@ 10 \text{ kPa}} = 0.00101 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,\text{in}} &= v_1(P_2 - P_1) \\ &= (0.00101 \text{ m}^3/\text{kg})(15,000 - 10 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 15.14 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 191.81 + 15.14 = 206.95 \text{ kJ/kg}$$

$$\begin{aligned} P_3 = 15 \text{ MPa} & \left\{ \begin{aligned} h_3 &= 3310.8 \text{ kJ/kg} \\ T_3 = 500^\circ\text{C} & \left\{ \begin{aligned} s_3 &= 6.3480 \text{ kJ/kg} \cdot \text{K} \end{aligned} \right. \end{aligned} \right. \end{aligned}$$

$$\begin{aligned} P_6 = 10 \text{ kPa} & \left\{ \begin{aligned} h_6 &= h_f + x_6 h_{fg} = 191.81 + (0.90)(2392.1) = 2344.7 \text{ kJ/kg} \\ s_6 = s_5 & \left\{ \begin{aligned} s_6 &= s_f + x_6 s_{fg} = 0.6492 + (0.90)(7.4996) = 7.3988 \text{ kJ/kg} \cdot \text{K} \end{aligned} \right. \end{aligned} \right. \end{aligned}$$

$$\begin{aligned} T_5 = 500^\circ\text{C} & \left\{ \begin{aligned} P_5 &= \mathbf{2150 \text{ kPa}} \text{ (the reheat pressure)} \\ s_5 = s_6 & \left\{ \begin{aligned} h_5 &= 3466.61 \text{ kJ/kg} \end{aligned} \right. \end{aligned} \right. \end{aligned}$$

$$\begin{aligned} P_4 = 2.15 \text{ MPa} & \left\{ \begin{aligned} h_4 &= 2817.2 \text{ kJ/kg} \\ s_4 = s_3 & \end{aligned} \right. \end{aligned}$$

(b) The rate of heat supply is

$$\begin{aligned} \dot{Q}_{\text{in}} &= \dot{m}[(h_3 - h_2) + (h_5 - h_4)] \\ &= (12 \text{ kg/s})(3310.8 - 206.95 + 3466.61 - 2817.2) \text{ kJ/kg} \\ &= \mathbf{45,039 \text{ kW}} \end{aligned}$$

(c) The thermal efficiency is determined from

$$\dot{Q}_{\text{out}} = \dot{m}(h_6 - h_1) = (12 \text{ kg/s})(2344.7 - 191.81) \text{ kJ/kg} = 25,835 \text{ kJ/s}$$

Thus,

$$\eta_{\text{th}} = 1 - \frac{\dot{Q}_{\text{out}}}{\dot{Q}_{\text{in}}} = 1 - \frac{25,834 \text{ kJ/s}}{45,039 \text{ kJ/s}} = \mathbf{42.6\%}$$

10-36 A steam power plant that operates on a reheat Rankine cycle is considered. The condenser pressure, the net power output, and the thermal efficiency are to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis (a) From the steam tables (Tables A-4, A-5, and A-6),

$$\left. \begin{array}{l} P_3 = 12.5 \text{ MPa} \\ T_3 = 550^\circ\text{C} \end{array} \right\} \begin{array}{l} h_3 = 3476.5 \text{ kJ/kg} \\ s_3 = 6.6317 \text{ kJ/kg}\cdot\text{K} \end{array}$$

$$\left. \begin{array}{l} P_4 = 2 \text{ MPa} \\ s_{4s} = s_3 \end{array} \right\} h_{4s} = 2948.1 \text{ kJ/kg}$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}}$$

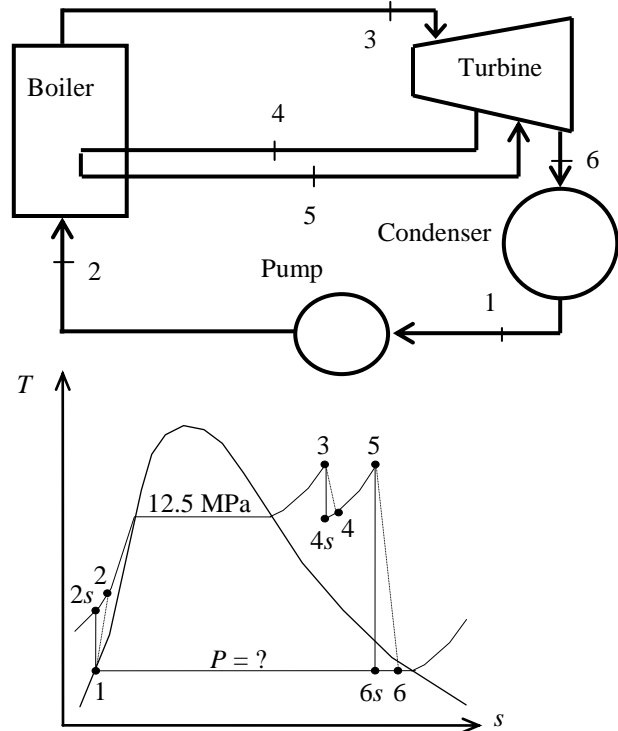

$$\begin{aligned} \rightarrow h_4 &= h_3 - \eta_T (h_3 - h_{4s}) \\ &= 3476.5 - (0.85)(3476.5 - 2948.1) \\ &= 3027.3 \text{ kJ/kg} \end{aligned}$$

$$\left. \begin{array}{l} P_5 = 2 \text{ MPa} \\ T_5 = 450^\circ\text{C} \end{array} \right\} \begin{array}{l} h_5 = 3358.2 \text{ kJ/kg} \\ s_5 = 7.2815 \text{ kJ/kg}\cdot\text{K} \end{array}$$

$$\left. \begin{array}{l} P_6 = ? \\ x_6 = 0.95 \end{array} \right\} h_6 = \quad (\text{Eq. 1})$$

$$\left. \begin{array}{l} P_6 = ? \\ s_6 = s_5 \end{array} \right\} h_{6s} = \quad (\text{Eq. 2})$$

$$\eta_T = \frac{h_5 - h_6}{h_5 - h_{6s}} \rightarrow h_6 = h_5 - \eta_T (h_5 - h_{6s}) = 3358.2 - (0.85)(3358.2 - h_{6s}) \quad (\text{Eq. 3})$$

The pressure at state 6 may be determined by a trial-error approach from the steam tables or by using EES from the above three equations:

$$P_6 = \mathbf{9.73 \text{ kPa}}, \quad h_6 = 2463.3 \text{ kJ/kg},$$

(b) Then,

$$h_1 = h_f @ 9.73 \text{ kPa} = 189.57 \text{ kJ/kg}$$

$$v_1 = v_f @ 10 \text{ kPa} = 0.001010 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,\text{in}} &= v_1 (P_2 - P_1) / \eta_p \\ &= (0.00101 \text{ m}^3/\text{kg})(12,500 - 9.73 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa}\cdot\text{m}^3} \right) / (0.90) \\ &= 14.02 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 189.57 + 14.02 = 203.59 \text{ kJ/kg}$$

Cycle analysis:

$$q_{\text{in}} = (h_3 - h_2) + (h_5 - h_4) = 3476.5 - 203.59 + 3358.2 - 2463.3 = 3603.8 \text{ kJ/kg}$$

$$q_{\text{out}} = h_6 - h_1 = 2463.3 - 189.57 = 2273.7 \text{ kJ/kg}$$

$$\dot{W}_{\text{net}} = \dot{m}(q_{\text{in}} - q_{\text{out}}) = (7.7 \text{ kg/s})(3603.8 - 2273.7) \text{ kJ/kg} = \mathbf{10,242 \text{ kW}}$$

(c) The thermal efficiency is

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{2273.7 \text{ kJ/kg}}{3603.8 \text{ kJ/kg}} = 0.369 = \mathbf{36.9\%}$$

10-37 A steam power plant that operates on a reheat Rankine cycle is considered. The quality (or temperature, if superheated) of the steam at the turbine exit, the thermal efficiency of the cycle, and the mass flow rate of the steam are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_{f@10\text{ kPa}} = 191.81 \text{ kJ/kg}$$

$$v_1 = v_{f@10\text{ kPa}} = 0.001010 \text{ m}^3/\text{kg}$$

$$w_{p,\text{in}} = v_1(P_2 - P_1)/\eta_p = (0.00101 \text{ m}^3/\text{kg})(10,000 - 10 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) / (0.95) = 10.62 \text{ kJ/kg}$$

$$h_2 = h_1 + w_{p,\text{in}} = 191.81 + 10.62 = 202.43 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 10 \text{ MPa} \\ T_3 = 500^\circ\text{C} \end{array} \right\} \begin{array}{l} h_3 = 3375.1 \text{ kJ/kg} \\ s_3 = 6.5995 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_{4s} = 1 \text{ MPa} \\ s_{4s} = s_3 \end{array} \right\} h_{4s} = 2783.8 \text{ kJ/kg}$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow h_4 = h_3 - \eta_T(h_3 - h_{4s}) = 3375.1 - (0.80)(3375.1 - 2783.7) = 2902.0 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_5 = 1 \text{ MPa} \\ T_5 = 500^\circ\text{C} \end{array} \right\} \begin{array}{l} h_5 = 3479.1 \text{ kJ/kg} \\ s_5 = 7.7642 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_{6s} = 10 \text{ kPa} \\ s_{6s} = s_5 \end{array} \right\} \begin{array}{l} x_{6s} = \frac{s_{6s} - s_f}{s_{fg}} = \frac{7.7642 - 0.6492}{7.4996} = 0.9487 \text{ (at turbine exit)} \\ h_{6s} = h_f + x_{6s}h_{fg} = 191.81 + (0.9487)(2392.1) = 2461.2 \text{ kJ/kg} \end{array}$$

$$\eta_T = \frac{h_5 - h_6}{h_5 - h_{6s}} \longrightarrow h_6 = h_5 - \eta_T(h_5 - h_{6s}) = 3479.1 - (0.80)(3479.1 - 2461.2) = 2664.8 \text{ kJ/kg} > h_g \text{ (superheated vapor)}$$

From steam tables at 10 kPa we read $T_6 = 88.1^\circ\text{C}$.

$$(b) \quad w_{T,\text{out}} = (h_3 - h_4) + (h_5 - h_6) = 3375.1 - 2902.0 + 3479.1 - 2664.8 = 1287.4 \text{ kJ/kg}$$

$$q_{\text{in}} = (h_3 - h_2) + (h_5 - h_4) = 3375.1 - 202.43 + 3479.1 - 2902.0 = 3749.8 \text{ kJ/kg}$$

$$w_{\text{net}} = w_{T,\text{out}} - w_{p,\text{in}} = 1287.4 - 10.62 = 1276.8 \text{ kJ/kg}$$

Thus the thermal efficiency is

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{1276.8 \text{ kJ/kg}}{3749.8 \text{ kJ/kg}} = \mathbf{34.1\%}$$

(c) The mass flow rate of the steam is

$$\dot{m} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{80,000 \text{ kJ/s}}{1276.9 \text{ kJ/kg}} = \mathbf{62.7 \text{ kg/s}}$$

10-38 A steam power plant that operates on the ideal reheat Rankine cycle is considered. The quality (or temperature, if superheated) of the steam at the turbine exit, the thermal efficiency of the cycle, and the mass flow rate of the steam are to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis (a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_{f@10\text{ kPa}} = 191.81 \text{ kJ/kg}$$

$$v_1 = v_{f@10\text{ kPa}} = 0.00101 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,\text{in}} &= v_1(P_2 - P_1) \\ &= (0.00101 \text{ m}^3/\text{kg})(10,000 - 10 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 10.09 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 191.81 + 10.09 = 201.90 \text{ kJ/kg}$$

$$\left. \begin{aligned} P_3 &= 10 \text{ MPa} \\ T_3 &= 500^\circ\text{C} \end{aligned} \right\} \begin{aligned} h_3 &= 3375.1 \text{ kJ/kg} \\ s_3 &= 6.5995 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

$$\left. \begin{aligned} P_4 &= 1 \text{ MPa} \\ s_4 &= s_3 \end{aligned} \right\} h_4 = 2783.8 \text{ kJ/kg}$$

$$\left. \begin{aligned} P_5 &= 1 \text{ MPa} \\ T_5 &= 500^\circ\text{C} \end{aligned} \right\} \begin{aligned} h_5 &= 3479.1 \text{ kJ/kg} \\ s_5 &= 7.7642 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

$$\left. \begin{aligned} P_6 &= 10 \text{ kPa} \\ s_6 &= s_5 \end{aligned} \right\} \begin{aligned} x_6 &= \frac{s_6 - s_f}{s_{fg}} = \frac{7.7642 - 0.6492}{7.4996} = \mathbf{0.9487} \text{ (at turbine exit)} \\ h_6 &= h_f + x_6 h_{fg} = 191.81 + (0.9487)(2392.1) = 2461.2 \text{ kJ/kg} \end{aligned}$$

$$(b) \quad w_{T,\text{out}} = (h_3 - h_4) + (h_5 - h_6) = 3375.1 - 2783.7 + 3479.1 - 2461.2 = 1609.3 \text{ kJ/kg}$$

$$q_{\text{in}} = (h_3 - h_2) + (h_5 - h_4) = 3375.1 - 201.90 + 3479.1 - 2783.7 = 3868.5 \text{ kJ/kg}$$

$$w_{\text{net}} = w_{T,\text{out}} - w_{p,\text{in}} = 1609.3 - 10.09 = 1599.3 \text{ kJ/kg}$$

Thus the thermal efficiency is

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{1599.3 \text{ kJ/kg}}{3868.5 \text{ kJ/kg}} = \mathbf{41.3\%}$$

(c) The mass flow rate of the steam is

$$\dot{m} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{80,000 \text{ kJ/s}}{1599.3 \text{ kJ/kg}} = \mathbf{50.0 \text{ kg/s}}$$

Regenerative Rankine Cycle

10-39C This is a smart idea because we waste little work potential but we save a lot from the heat input. The extracted steam has little work potential left, and most of its energy would be part of the heat rejected anyway. Therefore, by regeneration, we utilize a considerable amount of heat by sacrificing little work output.

10-40C Both cycles would have the same efficiency.

10-41C In open feedwater heaters, the two fluids actually mix, but in closed feedwater heaters there is no mixing.

10-42C Moisture content remains the same, everything else decreases.

10-43E Feedwater is heated by steam in a feedwater heater of a regenerative Rankine cycle. The ratio of the bleed steam mass flow rate to the inlet feedwater mass flow rate is to be determined.

Assumptions 1 This is a steady-flow process since there is no change with time. **2** Kinetic and potential energy changes are negligible. **3** There are no work interactions. **4** The device is adiabatic and thus heat transfer is negligible.

Properties From the steam tables (Tables A-4E through A-6E or EES),

$$h_1 \cong h_f @ 110^\circ\text{F} = 78.02 \text{ Btu/lbm}$$

$$\left. \begin{array}{l} P_2 = 40 \text{ psia} \\ T_2 = 280^\circ\text{F} \end{array} \right\} h_2 = 1176.6 \text{ Btu/lbm}$$

$$h_3 \cong h_f @ 250^\circ\text{F} = 218.63 \text{ Btu/lbm}$$

Analysis We take the mixing chamber as the system, which is a control volume since mass crosses the boundary. The mass and energy balances for this steady-flow system can be expressed in the rate form as

Mass balance:

$$\begin{aligned} \dot{m}_{\text{in}} - \dot{m}_{\text{out}} &= \Delta \dot{m}_{\text{system}} \stackrel{\neq 0 \text{ (steady)}}{=} 0 \\ \dot{m}_{\text{in}} &= \dot{m}_{\text{out}} \\ \dot{m}_1 + \dot{m}_2 &= \dot{m}_3 \end{aligned}$$

Energy balance:

$$\underbrace{\dot{E}_{\text{in}} - \dot{E}_{\text{out}}}_{\text{Rate of net energy transfer by heat, work, and mass}} = \underbrace{\Delta \dot{E}_{\text{system}}}_{\text{Rate of change in internal, kinetic, potential, etc. energies}} \stackrel{\neq 0 \text{ (steady)}}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\dot{m}_1 h_1 + \dot{m}_2 h_2 = \dot{m}_3 h_3 \quad (\text{since } \dot{Q} = \dot{W} = \Delta \text{ke} \cong \Delta \text{pe} \cong 0)$$

$$\dot{m}_1 h_1 + \dot{m}_2 h_2 = (\dot{m}_1 + \dot{m}_2) h_3$$

Solving for the bleed steam mass flow rate to the inlet feedwater mass flow rate, and substituting gives

$$\frac{\dot{m}_2}{\dot{m}_1} = \frac{h_1 - h_3}{h_3 - h_2} = \frac{(78.02 - 218.63) \text{ kJ/kg}}{(218.63 - 1176.6) \text{ kJ/kg}} = \mathbf{0.147}$$

10-44 In a regenerative Rankine cycle, the closed feedwater heater with a pump as shown in the figure is arranged so that the water at state 5 is mixed with the water at state 2 to form a feedwater which is a saturated liquid. The amount of bleed steam required to heat 1 kg of feedwater is to be determined.

Assumptions 1 This is a steady-flow process since there is no change with time. **2** Kinetic and potential energy changes are negligible. **3** There are no work interactions. **4** The device is adiabatic and thus heat transfer is negligible.

Properties From the steam tables (Tables A-4 through A-6),

$$\left. \begin{array}{l} P_1 = 7000 \text{ kPa} \\ T_1 = 260^\circ\text{C} \end{array} \right\} h_1 \cong h_f @ 260^\circ\text{C} = 1134.8 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 6000 \text{ kPa} \\ T_3 = 325^\circ\text{C} \end{array} \right\} h_3 = 2969.5 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_6 = 7000 \text{ kPa} \\ x_6 = 0 \end{array} \right\} h_6 = h_f @ 7000\text{kPa} = 1267.5 \text{ kJ/kg}$$

Analysis We take the entire unit as the system, which is a control volume since mass crosses the boundary. The energy balance for this steady-flow system can be expressed in the rate form as

$$\underbrace{\dot{E}_{in} - \dot{E}_{out}}_{\text{Rate of net energy transfer by heat, work, and mass}} = \underbrace{\Delta \dot{E}_{system}}_{\substack{\neq 0 \text{ (steady)} \\ \text{Rate of change in internal, kinetic, potential, etc. energies}}} = 0$$

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{m}_1 h_1 + \dot{m}_3 h_3 + \dot{m}_3 w_{p,in} = \dot{m}_6 h_6$$

$$\dot{m}_1 h_1 + \dot{m}_3 h_3 + \dot{m}_3 w_{p,in} = (\dot{m}_1 + \dot{m}_3) h_6$$

Solving this for \dot{m}_3 ,

$$\dot{m}_3 = \dot{m}_1 \frac{h_6 - h_1}{(h_3 - h_6) + w_{p,in}} = (1 \text{ kg/s}) \frac{1267.5 - 1134.8}{2969.5 - 1267.5 + 1.319} = \mathbf{0.0779 \text{ kg/s}}$$

where

$$\begin{aligned} w_{p,in} &= v_4 (P_5 - P_4) = v_{f @ 6000\text{kPa}} (P_5 - P_4) \\ &= (0.001319 \text{ m}^3/\text{kg})(7000 - 6000) \text{ kPa} \left(\frac{1 \text{ kPa}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 1.319 \text{ kJ/kg} \end{aligned}$$

10-45 A steam power plant that operates on an ideal regenerative Rankine cycle with an open feedwater heater is considered. The net work output per kg of steam and the thermal efficiency of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 20 \text{ kPa} = 251.42 \text{ kJ/kg}$$

$$v_1 = v_f @ 20 \text{ kPa} = 0.001017 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{pI,in} &= v_1(P_2 - P_1) \\ &= (0.001017 \text{ m}^3/\text{kg})(400 - 20 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 0.39 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{pI,in} = 251.42 + 0.39 = 251.81 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 0.4 \text{ MPa} \\ \text{sat. liquid} \end{array} \right\} \begin{array}{l} h_3 = h_f @ 0.4 \text{ MPa} = 604.66 \text{ kJ/kg} \\ v_3 = v_f @ 0.4 \text{ MPa} = 0.001084 \text{ m}^3/\text{kg} \end{array}$$

$$w_{pII,in} = v_3(P_4 - P_3) = (0.001084 \text{ m}^3/\text{kg})(6000 - 400 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) = 6.07 \text{ kJ/kg}$$

$$h_4 = h_3 + w_{pII,in} = 604.66 + 6.07 = 610.73 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_5 = 6 \text{ MPa} \\ T_5 = 450^\circ\text{C} \end{array} \right\} \begin{array}{l} h_5 = 3302.9 \text{ kJ/kg} \\ s_5 = 6.7219 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_6 = 0.4 \text{ MPa} \\ s_6 = s_5 \end{array} \right\} \begin{array}{l} x_6 = \frac{s_6 - s_f}{s_{fg}} = \frac{6.7219 - 1.7765}{5.1191} = 0.9661 \\ h_6 = h_f + x_6 h_{fg} = 604.66 + (0.9661)(2133.4) = 2665.7 \text{ kJ/kg} \end{array}$$

$$\left. \begin{array}{l} P_7 = 20 \text{ kPa} \\ s_7 = s_5 \end{array} \right\} \begin{array}{l} x_7 = \frac{s_7 - s_f}{s_{fg}} = \frac{6.7219 - 0.8320}{7.0752} = 0.8325 \\ h_7 = h_f + x_7 h_{fg} = 251.42 + (0.8325)(2357.5) = 2214.0 \text{ kJ/kg} \end{array}$$

The fraction of steam extracted is determined from the steady-flow energy balance equation applied to the feedwater heater.

Noting that $\dot{Q} \cong \dot{W} \cong \Delta ke \cong \Delta pe \cong 0$,

$$\begin{aligned} \dot{E}_{in} - \dot{E}_{out} &= \Delta \dot{E}_{system} \stackrel{\text{0 (steady)}}{=} 0 \\ \dot{E}_{in} &= \dot{E}_{out} \\ \sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \longrightarrow \dot{m}_6 h_6 + \dot{m}_2 h_2 = \dot{m}_3 h_3 \longrightarrow y h_6 + (1-y) h_2 = 1(h_3) \end{aligned}$$

where y is the fraction of steam extracted from the turbine ($= \dot{m}_6 / \dot{m}_3$). Solving for y ,

$$y = \frac{h_3 - h_2}{h_6 - h_2} = \frac{604.66 - 251.81}{2665.7 - 251.81} = 0.1462$$

Then,

$$q_{in} = h_5 - h_4 = 3302.9 - 610.73 = 2692.2 \text{ kJ/kg}$$

$$q_{out} = (1-y)(h_7 - h_1) = (1-0.1462)(2214.0 - 251.42) = 1675.7 \text{ kJ/kg}$$

and $w_{net} = q_{in} - q_{out} = 2692.2 - 1675.7 = \mathbf{1016.5 \text{ kJ/kg}}$

(b) The thermal efficiency is determined from

$$\eta_{th} = 1 - \frac{q_{out}}{q_{in}} = 1 - \frac{1675.7 \text{ kJ/kg}}{2692.2 \text{ kJ/kg}} = \mathbf{37.8\%}$$

10-46 A steam power plant that operates on an ideal regenerative Rankine cycle with a closed feedwater heater is considered. The net work output per kg of steam and the thermal efficiency of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis (a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 20 \text{ kPa} = 251.42 \text{ kJ/kg}$$

$$v_1 = v_f @ 20 \text{ kPa} = 0.001017 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{pI,in} &= v_1(P_2 - P_1) \\ &= (0.001017 \text{ m}^3/\text{kg})(6000 - 20 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 6.08 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{pI,in} = 251.42 + 6.08 = 257.50 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 0.4 \text{ MPa} \\ \text{sat. liquid} \end{array} \right\} \begin{array}{l} h_3 = h_f @ 0.4 \text{ MPa} = 604.66 \text{ kJ/kg} \\ v_3 = v_f @ 0.4 \text{ MPa} = 0.001084 \text{ m}^3/\text{kg} \end{array}$$

$$w_{pII,in} = v_3(P_9 - P_3) = (0.001084 \text{ m}^3/\text{kg})(6000 - 400 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) = 6.07 \text{ kJ/kg}$$

$$h_9 = h_3 + w_{pII,in} = 604.66 + 6.07 = 610.73 \text{ kJ/kg}$$

$$h_8 = h_3 + v_3(P_8 - P_3) = h_9 = 610.73 \text{ kJ/kg}$$

Also, $h_4 = h_9 = h_8 = 610.73 \text{ kJ/kg}$ since the two fluid streams which are being mixed have the same enthalpy.

$$\left. \begin{array}{l} P_5 = 6 \text{ MPa} \\ T_5 = 450^\circ\text{C} \end{array} \right\} \begin{array}{l} h_5 = 3302.9 \text{ kJ/kg} \\ s_5 = 6.7219 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_6 = 0.4 \text{ MPa} \\ s_6 = s_5 \end{array} \right\} \begin{array}{l} x_6 = \frac{s_6 - s_f}{s_{fg}} = \frac{6.7219 - 1.7765}{5.1191} = 0.9661 \\ h_6 = h_f + x_6 h_{fg} = 604.66 + (0.9661)(2133.4) = 2665.7 \text{ kJ/kg} \end{array}$$

$$\left. \begin{array}{l} P_7 = 20 \text{ kPa} \\ s_7 = s_5 \end{array} \right\} \begin{array}{l} x_7 = \frac{s_7 - s_f}{s_{fg}} = \frac{6.7219 - 0.8320}{7.0752} = 0.8325 \\ h_7 = h_f + x_7 h_{fg} = 251.42 + (0.8325)(2357.5) = 2214.0 \text{ kJ/kg} \end{array}$$

The fraction of steam extracted is determined from the steady-flow energy balance equation applied to the feedwater heater.

Noting that $\dot{Q} \cong \dot{W} \cong \Delta \text{ke} \cong \Delta \text{pe} \cong 0$,

$$\begin{aligned} \dot{E}_{in} - \dot{E}_{out} &= \Delta \dot{E}_{system} \stackrel{\text{steady}}{\cong} 0 \\ \dot{E}_{in} &= \dot{E}_{out} \\ \sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \longrightarrow \dot{m}_2(h_8 - h_2) = \dot{m}_6(h_6 - h_3) \longrightarrow (1 - y)(h_8 - h_2) = y(h_6 - h_3) \end{aligned}$$

where y is the fraction of steam extracted from the turbine ($= \dot{m}_6 / \dot{m}_5$). Solving for y ,

$$y = \frac{h_8 - h_2}{(h_6 - h_3) + (h_8 - h_2)} = \frac{610.73 - 257.50}{2665.7 - 604.66 + 610.73 - 257.50} = 0.1463$$

Then,

$$\begin{aligned} q_{in} &= h_5 - h_4 = 3302.9 - 610.73 = 2692.2 \text{ kJ/kg} \\ q_{out} &= (1 - y)(h_7 - h_1) = (1 - 0.1463)(2214.0 - 251.42) = 1675.4 \text{ kJ/kg} \end{aligned}$$

and $w_{net} = q_{in} - q_{out} = 2692.2 - 1675.4 = \mathbf{1016.8 \text{ kJ/kg}}$

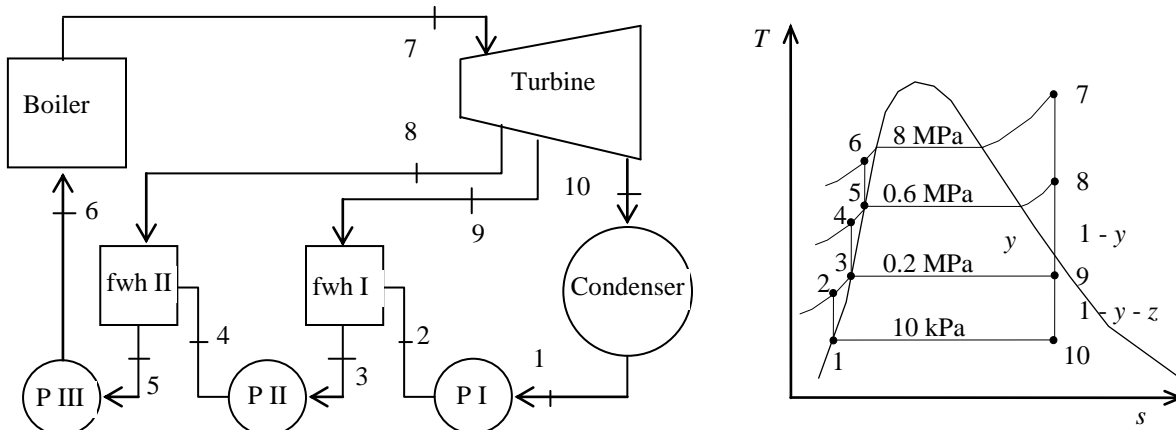

(b) The thermal efficiency is determined from

$$\eta_{th} = 1 - \frac{q_{out}}{q_{in}} = 1 - \frac{1675.4 \text{ kJ/kg}}{2692.2 \text{ kJ/kg}} = \mathbf{37.8\%}$$

10-47 A steam power plant operates on an ideal regenerative Rankine cycle with two open feedwater heaters. The net power output of the power plant and the thermal efficiency of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis

(a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 10 \text{ kPa} = 191.81 \text{ kJ/kg}$$

$$\nu_1 = \nu_f @ 10 \text{ kPa} = 0.001010 \text{ m}^3/\text{kg}$$

$$w_{pI, \text{in}} = \nu_1 (P_2 - P_1) = (0.001010 \text{ m}^3/\text{kg})(200 - 10 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) = 0.192 \text{ kJ/kg}$$

$$h_2 = h_1 + w_{pI, \text{in}} = 191.81 + 0.192 = 192.00 \text{ kJ/kg}$$

$$P_3 = 0.2 \text{ MPa} \left\{ \begin{array}{l} h_3 = h_f @ 0.2 \text{ MPa} = 504.71 \text{ kJ/kg} \\ \nu_3 = \nu_f @ 0.2 \text{ MPa} = 0.001061 \text{ m}^3/\text{kg} \end{array} \right.$$

$$w_{pII, \text{in}} = \nu_3 (P_4 - P_3) = (0.001061 \text{ m}^3/\text{kg})(600 - 200 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) = 0.42 \text{ kJ/kg}$$

$$h_4 = h_3 + w_{pII, \text{in}} = 504.71 + 0.42 = 505.13 \text{ kJ/kg}$$

$$P_5 = 0.6 \text{ MPa} \left\{ \begin{array}{l} h_5 = h_f @ 0.6 \text{ MPa} = 670.38 \text{ kJ/kg} \\ \nu_5 = \nu_f @ 0.6 \text{ MPa} = 0.001101 \text{ m}^3/\text{kg} \end{array} \right.$$

$$w_{pIII, \text{in}} = \nu_5 (P_6 - P_5) = (0.001101 \text{ m}^3/\text{kg})(8000 - 600 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) = 8.144 \text{ kJ/kg}$$

$$h_6 = h_5 + w_{pIII, \text{in}} = 670.38 + 8.144 = 678.52 \text{ kJ/kg}$$

$$P_7 = 8 \text{ MPa} \left\{ \begin{array}{l} h_7 = 3521.8 \text{ kJ/kg} \\ T_7 = 550^\circ\text{C} \end{array} \right. \left. \begin{array}{l} s_7 = 6.8800 \text{ kJ/kg} \cdot \text{K} \end{array} \right.$$

$$P_8 = 0.6 \text{ MPa} \left\{ \begin{array}{l} h_8 = 2809.6 \text{ kJ/kg} \\ s_8 = s_7 \end{array} \right.$$

$$P_9 = 0.2 \text{ MPa} \left\{ \begin{array}{l} x_9 = \frac{s_9 - s_f}{s_{fg}} = \frac{6.8800 - 1.5302}{5.5968} = 0.9559 \\ s_9 = s_7 \end{array} \right.$$

$$h_9 = h_f + x_9 h_{fg} = 504.71 + (0.9559)(2201.6) = 2609.1 \text{ kJ/kg}$$

$$P_{10} = 10 \text{ kPa} \quad \left\{ \begin{array}{l} x_{10} = \frac{s_{10} - s_f}{s_{fg}} = \frac{6.8800 - 0.6492}{7.4996} = 0.8308 \\ s_{10} = s_7 \end{array} \right. \quad \left. \begin{array}{l} h_{10} = h_f + x_{10}h_{fg} = 191.81 + (0.8308)(2392.1) = 2179.2 \text{ kJ/kg} \end{array} \right.$$

The fraction of steam extracted is determined from the steady-flow energy balance equation applied to the feedwater heaters. Noting that $\dot{Q} \cong \dot{W} \cong \Delta ke \cong \Delta pe \cong 0$,

FWH-2:

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \stackrel{\phi^0(\text{steady})}{=} 0 \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \longrightarrow \dot{m}_8 h_8 + \dot{m}_4 h_4 = \dot{m}_5 h_5 \longrightarrow y h_8 + (1-y) h_4 = 1(h_5) \end{aligned}$$

where y is the fraction of steam extracted from the turbine ($= \dot{m}_8 / \dot{m}_5$). Solving for y ,

$$y = \frac{h_5 - h_4}{h_8 - h_4} = \frac{670.38 - 505.13}{2809.6 - 505.13} = 0.07171$$

FWH-1:

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \longrightarrow \dot{m}_9 h_9 + \dot{m}_2 h_2 = \dot{m}_3 h_3 \longrightarrow z h_9 + (1-y-z) h_2 = (1-y) h_3$$

where z is the fraction of steam extracted from the turbine ($= \dot{m}_9 / \dot{m}_5$) at the second stage. Solving for z ,

$$z = \frac{h_3 - h_2}{h_9 - h_2} (1-y) = \frac{504.71 - 192.00}{2609.1 - 192.00} (1 - 0.07171) = 0.1201$$

Then,

$$\begin{aligned} q_{\text{in}} &= h_7 - h_6 = 3521.8 - 678.52 = 2843.3 \text{ kJ/kg} \\ q_{\text{out}} &= (1-y-z)(h_{10} - h_1) = (1 - 0.07171 - 0.1201)(2179.2 - 191.81) = 1606.2 \text{ kJ/kg} \\ w_{\text{net}} &= q_{\text{in}} - q_{\text{out}} = 2843.3 - 1606.2 = 1237.2 \text{ kJ/kg} \end{aligned}$$

and

$$\dot{W}_{\text{net}} = \dot{m} w_{\text{net}} = (16 \text{ kg/s})(1237.2 \text{ kJ/kg}) = 19,795 \text{ kW} \cong \mathbf{19.8 \text{ MW}}$$

(b) The thermal efficiency is

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{1606.2 \text{ kJ/kg}}{2843.3 \text{ kJ/kg}} = 0.4351 = \mathbf{43.5\%}$$

10-48 An ideal regenerative Rankine cycle with a closed feedwater heater is considered. The work produced by the turbine, the work consumed by the pumps, and the heat added in the boiler are to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 20 \text{ kPa} = 251.42 \text{ kJ/kg}$$

$$\nu_1 = \nu_f @ 20 \text{ kPa} = 0.001017 \text{ m}^3/\text{kg}$$

$$w_{p,\text{in}} = \nu_1 (P_2 - P_1) \\ = (0.001017 \text{ m}^3/\text{kg})(3000 - 20) \text{ kPa} \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ = 3.03 \text{ kJ/kg}$$

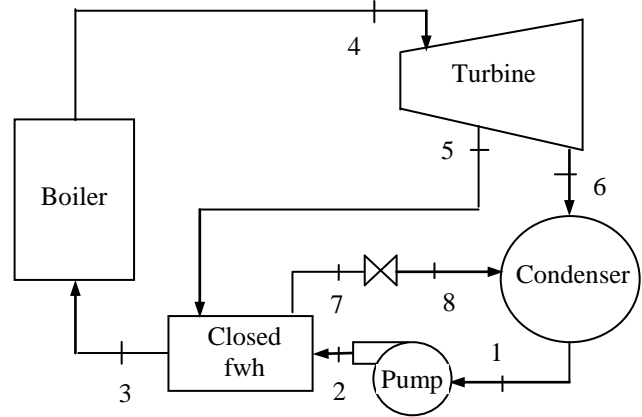

$$h_2 = h_1 + w_{p,\text{in}} = 251.42 + 3.03 = 254.45 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_4 = 3000 \text{ kPa} \\ T_4 = 350^\circ\text{C} \end{array} \right\} \begin{array}{l} h_4 = 3116.1 \text{ kJ/kg} \\ s_4 = 6.7450 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_5 = 1000 \text{ kPa} \\ s_5 = s_4 \end{array} \right\} h_5 = 2851.9 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_6 = 20 \text{ kPa} \\ s_6 = s_4 \end{array} \right\} x_6 = \frac{s_6 - s_f}{s_{fg}} = \frac{6.7450 - 0.8320}{7.0752} = 0.8357$$

$$h_6 = h_f + x_6 h_{fg} = 251.42 + (0.8357)(2357.5) = 2221.7 \text{ kJ/kg}$$

For an ideal closed feedwater heater, the feedwater is heated to the exit temperature of the extracted steam, which ideally leaves the heater as a saturated liquid at the extraction pressure.

$$\left. \begin{array}{l} P_7 = 1000 \text{ kPa} \\ x_7 = 0 \end{array} \right\} \begin{array}{l} h_7 = 762.51 \text{ kJ/kg} \\ T_7 = 179.9^\circ\text{C} \end{array}$$

$$h_8 = h_7 = 762.51 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 3000 \text{ kPa} \\ T_3 = T_7 = 209.9^\circ\text{C} \end{array} \right\} h_3 = 763.53 \text{ kJ/kg}$$

An energy balance on the heat exchanger gives the fraction of steam extracted from the turbine ($= \dot{m}_5 / \dot{m}_4$) for closed feedwater heater:

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \\ \dot{m}_5 h_5 + \dot{m}_2 h_2 = \dot{m}_3 h_3 + \dot{m}_7 h_7 \\ y h_5 + 1 h_2 = 1 h_3 + y h_7$$

Rearranging,

$$y = \frac{h_3 - h_2}{h_5 - h_7} = \frac{763.53 - 254.45}{2851.9 - 762.51} = 0.2437$$

Then,

$$w_{T,\text{out}} = h_4 - h_5 + (1 - y)(h_5 - h_6) = 3116.1 - 2851.9 + (1 - 0.2437)(2851.9 - 2221.7) = \mathbf{740.9 \text{ kJ/kg}}$$

$$w_{P,\text{in}} = \mathbf{3.03 \text{ kJ/kg}}$$

$$q_{\text{in}} = h_4 - h_3 = 3116.1 - 763.53 = \mathbf{2353 \text{ kJ/kg}}$$

Also, $w_{\text{net}} = w_{T,\text{out}} - w_{P,\text{in}} = 740.9 - 3.03 = 737.8 \text{ kJ/kg}$

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{737.8}{2353} = 0.3136$$

10-49 Problem 10-48 is reconsidered. The optimum bleed pressure for the open feedwater heater that maximizes the thermal efficiency of the cycle is to be determined by EES.

10-50 A regenerative Rankine cycle with a closed feedwater heater is considered. The thermal efficiency is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the steam tables (Tables A-4, A-5, and A-6 or EES),

$$h_1 = h_{f@20\text{kPa}} = 251.42 \text{ kJ/kg}$$

$$\nu_1 = \nu_{f@20\text{kPa}} = 0.001017 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,\text{in}} &= \nu_1(P_2 - P_1) \\ &= (0.001017 \text{ m}^3/\text{kg})(3000 - 20)\text{kPa} \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 3.03 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 251.42 + 3.03 = 254.45 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_4 = 3000 \text{ kPa} \\ T_4 = 350^\circ\text{C} \end{array} \right\} \begin{array}{l} h_4 = 3116.1 \text{ kJ/kg} \\ s_4 = 6.7450 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_5 = 1000 \text{ kPa} \\ s_{5s} = s_4 \end{array} \right\} h_{5s} = 2851.9 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_6 = 20 \text{ kPa} \\ s_{6s} = s_4 \end{array} \right\} \begin{array}{l} x_{6s} = \frac{s_{6s} - s_f}{s_{fg}} = \frac{6.7450 - 0.8320}{7.0752} = 0.8357 \\ h_{6s} = h_f + x_{6s}h_{fg} = 251.42 + (0.8357)(2357.5) = 2221.7 \text{ kJ/kg} \end{array}$$

$$\eta_T = \frac{h_4 - h_5}{h_4 - h_{5s}} \longrightarrow h_5 = h_4 - \eta_T(h_4 - h_{5s}) = 3116.1 - (0.90)(3116.1 - 2851.9) = 2878.3 \text{ kJ/kg}$$

$$\eta_T = \frac{h_4 - h_6}{h_4 - h_{6s}} \longrightarrow h_6 = h_4 - \eta_T(h_4 - h_{6s}) = 3116.1 - (0.90)(3116.1 - 2221.7) = 2311.1 \text{ kJ/kg}$$

For an ideal closed feedwater heater, the feedwater is heated to the exit temperature of the extracted steam, which ideally leaves the heater as a saturated liquid at the extraction pressure.

$$\left. \begin{array}{l} P_7 = 1000 \text{ kPa} \\ x_7 = 0 \end{array} \right\} \begin{array}{l} h_7 = 762.51 \text{ kJ/kg} \\ T_7 = 179.9^\circ\text{C} \end{array}$$

$$\left. \begin{array}{l} P_3 = 3000 \text{ kPa} \\ T_3 = T_7 = 209.9^\circ\text{C} \end{array} \right\} h_3 = 763.53 \text{ kJ/kg}$$

An energy balance on the heat exchanger gives the fraction of steam extracted from the turbine ($= \dot{m}_5 / \dot{m}_4$) for closed feedwater heater:

$$\begin{aligned} \sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \\ \dot{m}_5 h_5 + \dot{m}_2 h_2 &= \dot{m}_3 h_3 + \dot{m}_7 h_7 \\ y h_5 + 1 h_2 &= 1 h_3 + y h_7 \end{aligned}$$

Rearranging,

$$y = \frac{h_3 - h_2}{h_5 - h_7} = \frac{763.53 - 254.45}{2878.3 - 762.51} = 0.2406$$

Then,

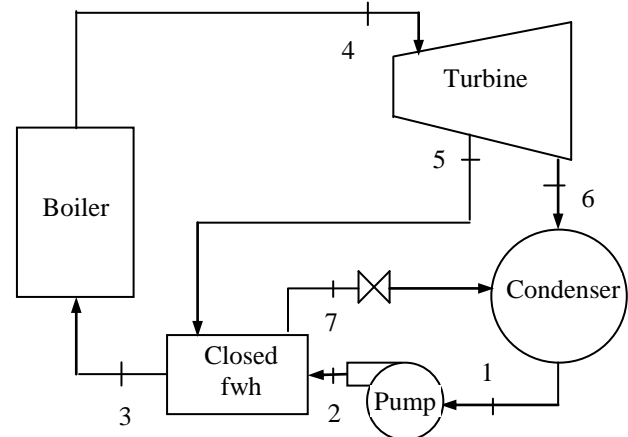

$$w_{T,\text{out}} = h_4 - h_5 + (1 - y)(h_5 - h_6) = 3116.1 - 2878.3 + (1 - 0.2406)(2878.3 - 2311.1) = 668.5 \text{ kJ/kg}$$

$$w_{p,\text{in}} = 3.03 \text{ kJ/kg}$$

$$q_{\text{in}} = h_4 - h_3 = 3116.1 - 763.53 = 2353 \text{ kJ/kg}$$

Also, $w_{\text{net}} = w_{T,\text{out}} - w_{p,\text{in}} = 668.5 - 3.03 = 665.5 \text{ kJ/kg}$

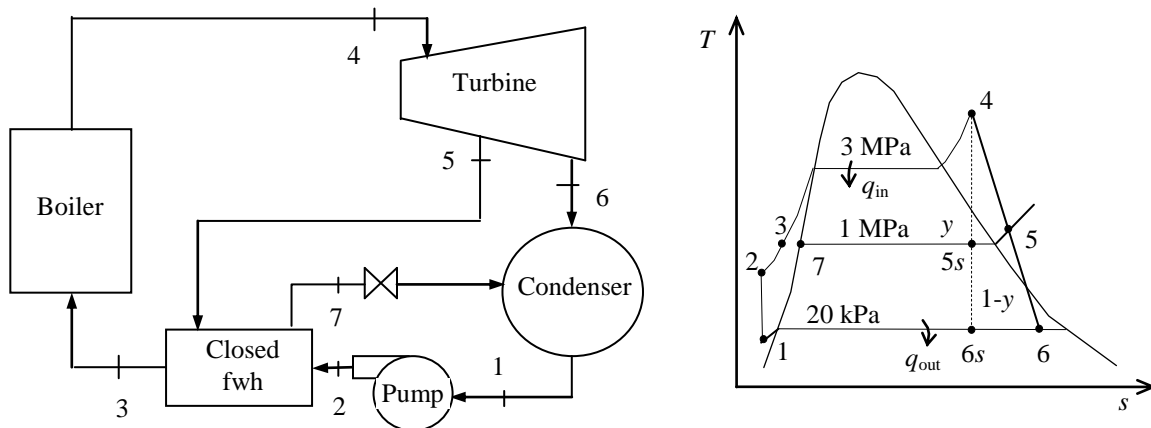

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{665.5}{2353} = 0.2829 = \mathbf{28.3\%}$$

10-51 A regenerative Rankine cycle with a closed feedwater heater is considered. The thermal efficiency is to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis From the steam tables (Tables A-4, A-5, and A-6 or EES),

When the liquid enters the pump 10°C cooler than a saturated liquid at the condenser pressure, the enthalpies become

$$\left. \begin{aligned} P_1 &= 20 \text{ kPa} \\ T_1 &= T_{\text{sat @ } 20 \text{ kPa}} - 10 = 60.06 - 10 \cong 50^\circ\text{C} \end{aligned} \right\} \begin{aligned} h_1 &\cong h_f @ 50^\circ\text{C} = 209.34 \text{ kJ/kg} \\ \nu_1 &\cong \nu_f @ 50^\circ\text{C} = 0.001012 \text{ m}^3/\text{kg} \end{aligned}$$

$$\begin{aligned} w_{\text{p,in}} &= \nu_1 (P_2 - P_1) \\ &= (0.001012 \text{ m}^3/\text{kg})(3000 - 20) \text{ kPa} \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 3.02 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{\text{p,in}} = 209.34 + 3.02 = 212.36 \text{ kJ/kg}$$

$$\left. \begin{aligned} P_4 &= 3000 \text{ kPa} \\ T_4 &= 350^\circ\text{C} \end{aligned} \right\} \begin{aligned} h_4 &= 3116.1 \text{ kJ/kg} \\ s_4 &= 6.7450 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

$$\left. \begin{aligned} P_5 &= 1000 \text{ kPa} \\ s_{5s} &= s_4 \end{aligned} \right\} h_{5s} = 2851.9 \text{ kJ/kg}$$

$$\left. \begin{aligned} P_6 &= 20 \text{ kPa} \\ s_{6s} &= s_4 \end{aligned} \right\} \begin{aligned} x_{6s} &= \frac{s_{6s} - s_f}{s_{fg}} = \frac{6.7450 - 0.8320}{7.0752} = 0.8357 \\ h_{6s} &= h_f + x_{6s} h_{fg} = 251.42 + (0.8357)(2357.5) = 2221.7 \text{ kJ/kg} \end{aligned}$$

$$\eta_T = \frac{h_4 - h_5}{h_4 - h_{5s}} \longrightarrow h_5 = h_4 - \eta_T (h_4 - h_{5s}) = 3116.1 - (0.90)(3116.1 - 2851.9) = 2878.3 \text{ kJ/kg}$$

$$\eta_T = \frac{h_4 - h_6}{h_4 - h_{6s}} \longrightarrow h_6 = h_4 - \eta_T (h_4 - h_{6s}) = 3116.1 - (0.90)(3116.1 - 2221.7) = 2311.1 \text{ kJ/kg}$$

For an ideal closed feedwater heater, the feedwater is heated to the exit temperature of the extracted steam, which ideally leaves the heater as a saturated liquid at the extraction pressure.

$$\left. \begin{aligned} P_7 &= 1000 \text{ kPa} \\ x_7 &= 0 \end{aligned} \right\} \begin{aligned} h_7 &= 762.51 \text{ kJ/kg} \\ T_7 &= 179.9^\circ\text{C} \end{aligned}$$

$$\left. \begin{aligned} P_3 &= 3000 \text{ kPa} \\ T_3 &= T_7 = 209.9^\circ\text{C} \end{aligned} \right\} h_3 = 763.53 \text{ kJ/kg}$$

An energy balance on the heat exchanger gives the fraction of steam extracted from the turbine ($= \dot{m}_5 / \dot{m}_4$) for closed feedwater heater:

$$\begin{aligned}\sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \\ \dot{m}_5 h_5 + \dot{m}_2 h_2 &= \dot{m}_3 h_3 + \dot{m}_7 h_7 \\ y h_5 + 1 h_2 &= 1 h_3 + y h_7\end{aligned}$$

Rearranging,

$$y = \frac{h_3 - h_2}{h_5 - h_7} = \frac{763.53 - 212.36}{2878.3 - 762.51} = 0.2605$$

Then,

$$w_{T,\text{out}} = h_4 - h_5 + (1 - y)(h_5 - h_6) = 3116.1 - 2878.3 + (1 - 0.2605)(2878.3 - 2311.1) = 657.2 \text{ kJ/kg}$$

$$w_{P,\text{in}} = 3.03 \text{ kJ/kg}$$

$$q_{\text{in}} = h_4 - h_3 = 3116.1 - 763.53 = 2353 \text{ kJ/kg}$$

Also,

$$w_{\text{net}} = w_{T,\text{out}} - w_{P,\text{in}} = 657.2 - 3.03 = 654.2 \text{ kJ/kg}$$

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{654.2}{2353} = \mathbf{0.2781}$$

10-52 The effect of pressure drop and non-isentropic turbine on the rate of heat input is to be determined for a given power plant.

10-53 A steam power plant operates on an ideal regenerative Rankine cycle with two feedwater heaters, one closed and one open. The mass flow rate of steam through the boiler for a net power output of 400 MW and the thermal efficiency of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_{f@10\text{ kPa}} = 191.81 \text{ kJ/kg}$$

$$\nu_1 = \nu_{f@10\text{ kPa}} = 0.00101 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{pI,\text{in}} &= \nu_1(P_2 - P_1) \\ &= (0.00101 \text{ m}^3/\text{kg})(600 - 10 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 0.60 \text{ kJ/kg} \\ h_2 &= h_1 + w_{pI,\text{in}} = 191.81 + 0.60 = 192.40 \text{ kJ/kg} \end{aligned}$$

$$\begin{aligned} P_3 = 0.6 \text{ MPa} \left. \begin{array}{l} h_3 = h_{f@0.3 \text{ MPa}} = 670.38 \text{ kJ/kg} \\ \text{sat. liquid} \end{array} \right\} \nu_3 = \nu_{f@0.3 \text{ MPa}} = 0.001101 \text{ m}^3/\text{kg} \end{aligned}$$

$$\begin{aligned} w_{pII,\text{in}} &= \nu_3(P_4 - P_3) \\ &= (0.001101 \text{ m}^3/\text{kg})(10000 - 600 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 10.35 \text{ kJ/kg} \end{aligned}$$

$$h_4 = h_3 + w_{pII,\text{in}} = 670.38 + 10.35 = 680.73 \text{ kJ/kg}$$

$$\begin{aligned} P_6 = 1.2 \text{ MPa} \left. \begin{array}{l} h_6 = h_7 = h_{f@1.2 \text{ MPa}} = 798.33 \text{ kJ/kg} \\ \text{sat. liquid} \end{array} \right\} T_6 = T_{\text{sat}@1.2 \text{ MPa}} = 188.0^\circ\text{C} \end{aligned}$$

$$T_6 = T_5, P_5 = 10 \text{ MPa} \rightarrow h_5 = 798.33 \text{ kJ/kg}$$

$$\begin{aligned} P_8 = 10 \text{ MPa} \left. \begin{array}{l} h_8 = 3625.8 \text{ kJ/kg} \\ T_8 = 600^\circ\text{C} \end{array} \right\} s_8 = 6.9045 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

$$\begin{aligned} P_9 = 1.2 \text{ MPa} \left. \begin{array}{l} h_9 = 2974.5 \text{ kJ/kg} \\ s_9 = s_8 \end{array} \right\} \end{aligned}$$

$$\begin{aligned} P_{10} = 0.6 \text{ MPa} \left. \begin{array}{l} h_{10} = 2820.9 \text{ kJ/kg} \\ s_{10} = s_8 \end{array} \right\} \end{aligned}$$

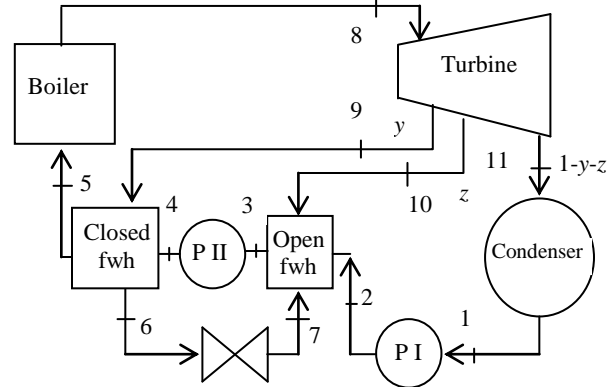

$$\begin{aligned} P_{11} = 10 \text{ kPa} \left. \begin{array}{l} x_{11} = \frac{s_{11} - s_f}{s_{fg}} = \frac{6.9045 - 0.6492}{7.4996} = 0.8341 \\ h_{11} = h_f + x_{11}h_{fg} = 191.81 + (0.8341)(2392.1) = 2187.0 \text{ kJ/kg} \end{array} \right\} \end{aligned}$$

The fraction of steam extracted is determined from the steady-flow energy balance equation applied to the feedwater heaters. Noting that $\dot{Q} \cong \dot{W} \cong \Delta ke \cong \Delta pe \cong 0$,

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \stackrel{\phi^0(\text{steady})}{=} 0 \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \longrightarrow \dot{m}_9(h_9 - h_6) = \dot{m}_5(h_5 - h_4) \longrightarrow y(h_9 - h_6) = (h_5 - h_4) \end{aligned}$$

where y is the fraction of steam extracted from the turbine ($= \dot{m}_{10} / \dot{m}_5$). Solving for y ,

$$y = \frac{h_5 - h_4}{h_9 - h_6} = \frac{798.33 - 680.73}{2974.5 - 798.33} = 0.05404$$

For the open FWH,

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\text{steady}}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \longrightarrow \dot{m}_7 h_7 + \dot{m}_2 h_2 + \dot{m}_{10} h_{10} = \dot{m}_3 h_3 \longrightarrow y h_7 + (1 - y - z) h_2 + z h_{10} = (1) h_3$$

where z is the fraction of steam extracted from the turbine ($= \dot{m}_9 / \dot{m}_5$) at the second stage. Solving for z ,

$$z = \frac{(h_3 - h_2) - y(h_7 - h_2)}{h_{10} - h_2} = \frac{670.38 - 192.40 - (0.05404)(798.33 - 192.40)}{2820.9 - 192.40} = 0.1694$$

Then,

$$q_{\text{in}} = h_8 - h_5 = 3625.8 - 798.33 = 2827 \text{ kJ/kg}$$

$$q_{\text{out}} = (1 - y - z)(h_{11} - h_1) = (1 - 0.05404 - 0.1694)(2187.0 - 191.81) = 1549 \text{ kJ/kg}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 2827 - 1549 = 1278 \text{ kJ/kg}$$

and

$$\dot{m} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{400,000 \text{ kJ/s}}{1278 \text{ kJ/kg}} = \mathbf{313.0 \text{ kg/s}}$$

$$(b) \quad \eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{1549 \text{ kJ/kg}}{2827 \text{ kJ/kg}} = 0.452 = \mathbf{45.2\%}$$

10-54 Problem 10-53 is reconsidered. The effects of turbine and pump efficiencies on the mass flow rate and thermal efficiency are to be investigated. Also, the T - s diagram is to be plotted.

Analysis The problem is solved using EES, and the solution is given below.

10-55 A steam power plant operates on an ideal reheat-regenerative Rankine cycle with an open feedwater heater. The mass flow rate of steam through the boiler and the thermal efficiency of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 10 \text{ kPa} = 191.81 \text{ kJ/kg}$$

$$v_1 = v_f @ 10 \text{ kPa} = 0.00101 \text{ m}^3/\text{kg}$$

$$w_{pI, \text{in}} = v_1(P_2 - P_1) = (0.00101 \text{ m}^3/\text{kg})(800 - 10 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right)$$

$$= 0.80 \text{ kJ/kg}$$

$$h_2 = h_1 + w_{pI, \text{in}} = 191.81 + 0.80 = 192.61 \text{ kJ/kg}$$

$$P_3 = 0.8 \text{ MPa} \left\{ \begin{array}{l} h_3 = h_f @ 0.8 \text{ MPa} = 720.87 \text{ kJ/kg} \\ \text{sat. liquid} \left\{ \begin{array}{l} v_3 = v_f @ 0.8 \text{ MPa} = 0.001115 \text{ m}^3/\text{kg} \end{array} \right. \end{array} \right.$$

$$w_{pII, \text{in}} = v_3(P_4 - P_3) = (0.001115 \text{ m}^3/\text{kg})(10,000 - 800 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right)$$

$$= 10.26 \text{ kJ/kg}$$

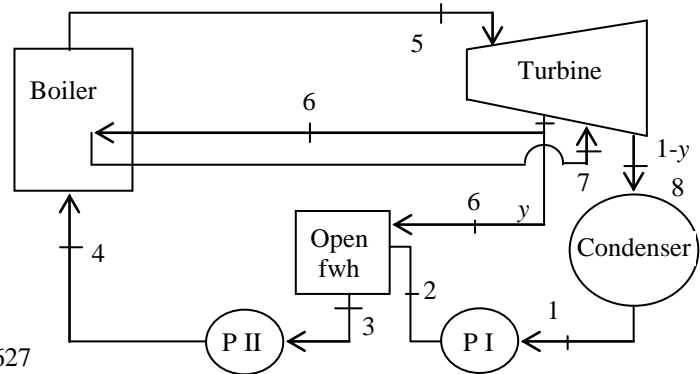

$$h_4 = h_3 + w_{pII, \text{in}} = 720.87 + 10.26 = 731.12 \text{ kJ/kg}$$

$$P_5 = 10 \text{ MPa} \left\{ \begin{array}{l} h_5 = 3502.0 \text{ kJ/kg} \\ T_5 = 550^\circ\text{C} \left\{ \begin{array}{l} s_5 = 6.7585 \text{ kJ/kg} \cdot \text{K} \end{array} \right. \end{array} \right.$$

$$P_6 = 0.8 \text{ MPa} \left\{ \begin{array}{l} h_6 = 2812.1 \text{ kJ/kg} \\ s_6 = s_5 \end{array} \right.$$

$$P_7 = 0.8 \text{ MPa} \left\{ \begin{array}{l} h_7 = 3481.3 \text{ kJ/kg} \\ T_7 = 500^\circ\text{C} \left\{ \begin{array}{l} s_7 = 7.8692 \text{ kJ/kg} \cdot \text{K} \end{array} \right. \end{array} \right.$$

$$P_8 = 10 \text{ kPa} \left\{ \begin{array}{l} x_8 = \frac{s_8 - s_f}{s_{fg}} = \frac{7.8692 - 0.6492}{7.4996} = 0.9627 \\ s_8 = s_7 \left\{ \begin{array}{l} h_8 = h_f + x_8 h_{fg} = 191.81 + (0.9627)(2392.1) = 2494.7 \text{ kJ/kg} \end{array} \right. \end{array} \right.$$

The fraction of steam extracted is determined from the steady-flow energy balance equation applied to the feedwater heaters. Noting that $\dot{Q} \cong \dot{W} \cong \Delta \text{ke} \cong \Delta \text{pe} \cong 0$,

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\phi^0(\text{steady})}{=} 0 \rightarrow \dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \longrightarrow \dot{m}_6 h_6 + \dot{m}_2 h_2 = \dot{m}_3 h_3 \longrightarrow y h_6 + (1 - y) h_2 = 1(h_3)$$

where y is the fraction of steam extracted from the turbine ($= \dot{m}_6 / \dot{m}_3$). Solving for y ,

$$y = \frac{h_3 - h_2}{h_6 - h_2} = \frac{720.87 - 192.61}{2812.1 - 192.61} = 0.2017$$

$$\text{Then, } q_{\text{in}} = (h_5 - h_4) + (1 - y)(h_7 - h_6) = (3502.0 - 731.12) + (1 - 0.2017)(3481.3 - 2812.1) = 3305.1 \text{ kJ/kg}$$

$$q_{\text{out}} = (1 - y)(h_8 - h_1) = (1 - 0.2017)(2494.7 - 191.81) = 1838.5 \text{ kJ/kg}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 3305.1 - 1838.5 = 1466.6 \text{ kJ/kg}$$

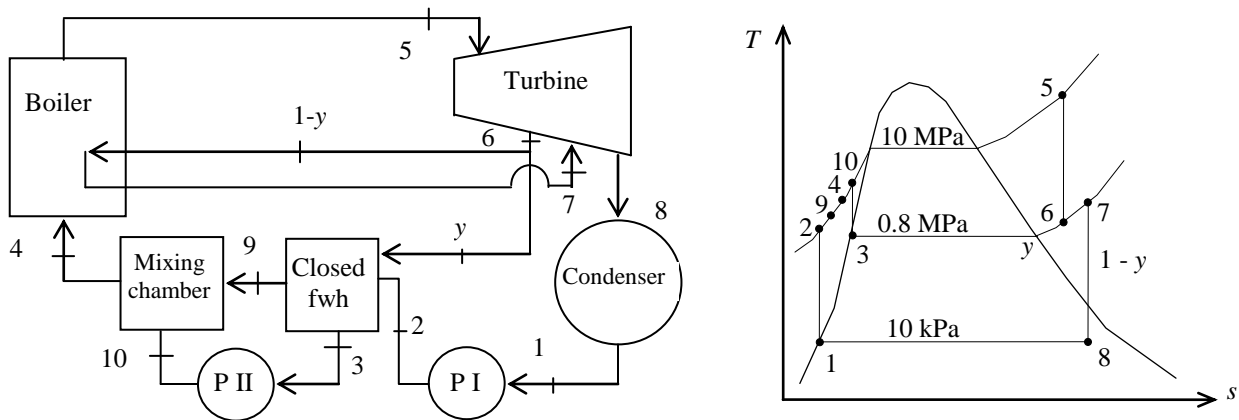

$$\text{and } \dot{m} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{80,000 \text{ kJ/s}}{1466.1 \text{ kJ/kg}} = \mathbf{54.5 \text{ kg/s}}$$

$$(b) \quad \eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{1466.1 \text{ kJ/kg}}{3305.1 \text{ kJ/kg}} = \mathbf{44.4\%}$$

10-56 A steam power plant operates on an ideal reheat-regenerative Rankine cycle with a closed feedwater heater. The mass flow rate of steam through the boiler and the thermal efficiency of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis

(a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_{f@10\text{kPa}} = 191.81 \text{ kJ/kg}$$

$$v_1 = v_{f@10\text{kPa}} = 0.00101 \text{ m}^3/\text{kg}$$

$$w_{pI,\text{in}} = v_1(P_2 - P_1) = (0.00101 \text{ m}^3/\text{kg})(10,000 - 10 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) = 10.09 \text{ kJ/kg}$$

$$h_2 = h_1 + w_{pI,\text{in}} = 191.81 + 10.09 = 201.90 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 0.8 \text{ MPa} \\ \text{sat. liquid} \end{array} \right\} \begin{array}{l} h_3 = h_{f@0.8 \text{ MPa}} = 720.87 \text{ kJ/kg} \\ v_3 = v_{f@0.8 \text{ MPa}} = 0.001115 \text{ m}^3/\text{kg} \end{array}$$

$$w_{pII,\text{in}} = v_3(P_4 - P_3) = (0.001115 \text{ m}^3/\text{kg})(10,000 - 800 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) = 10.26 \text{ kJ/kg}$$

$$h_4 = h_3 + w_{pII,\text{in}} = 720.87 + 10.26 = 731.13 \text{ kJ/kg}$$

Also, $h_4 = h_9 = h_{10} = 731.12 \text{ kJ/kg}$ since the two fluid streams that are being mixed have the same enthalpy.

$$\left. \begin{array}{l} P_5 = 10 \text{ MPa} \\ T_5 = 550^\circ\text{C} \end{array} \right\} \begin{array}{l} h_5 = 3502.0 \text{ kJ/kg} \\ s_5 = 6.7585 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_6 = 0.8 \text{ MPa} \\ s_6 = s_5 \end{array} \right\} h_6 = 2812.7 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_7 = 0.8 \text{ MPa} \\ T_7 = 500^\circ\text{C} \end{array} \right\} \begin{array}{l} h_7 = 3481.3 \text{ kJ/kg} \\ s_7 = 7.8692 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_8 = 10 \text{ kPa} \\ s_8 = s_7 \end{array} \right\} x_8 = \frac{s_8 - s_f}{s_{fg}} = \frac{7.8692 - 0.6492}{7.4996} = 0.9627$$

$$h_8 = h_f + x_8 h_{fg} = 191.81 + (0.9627)(2392.1) = 2494.7 \text{ kJ/kg}$$

The fraction of steam extracted is determined from the steady-flow energy balance equation applied to the feedwater heaters. Noting that $\dot{Q} \cong \dot{W} \cong \Delta ke \cong \Delta pe \cong 0$,

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\text{steady}}{\neq} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \longrightarrow \dot{m}_2 (h_9 - h_2) = \dot{m}_3 (h_6 - h_3) \longrightarrow (1 - y)(h_9 - h_2) = y(h_6 - h_3)$$

where y is the fraction of steam extracted from the turbine ($= \dot{m}_3 / \dot{m}_4$). Solving for y ,

$$y = \frac{h_9 - h_2}{(h_6 - h_3) + (h_9 - h_2)} = \frac{731.13 - 201.90}{2812.7 - 720.87 + 731.13 - 201.90} = 0.2019$$

Then,

$$q_{\text{in}} = (h_5 - h_4) + (1 - y)(h_7 - h_6) = (3502.0 - 731.13) + (1 - 0.2019)(3481.3 - 2812.7) = 3304.5 \text{ kJ/kg}$$

$$q_{\text{out}} = (1 - y)(h_8 - h_1) = (1 - 0.2019)(2494.7 - 191.81) = 1837.9 \text{ kJ/kg}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 3304.5 - 1837.8 = 1466.6 \text{ kJ/kg}$$

and

$$\dot{m} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{80,000 \text{ kJ/s}}{1467.1 \text{ kJ/kg}} = \mathbf{54.5 \text{ kg/s}}$$

$$(b) \quad \eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{1837.8 \text{ kJ/kg}}{3304.5 \text{ kJ/kg}} = \mathbf{44.4\%}$$

10-57 A Rankine steam cycle modified with two closed feedwater heaters is considered. The T - s diagram for the ideal cycle is to be sketched. The fraction of mass extracted for the closed feedwater heater z and the cooling water flow rate are to be determined. Also, the net power output and the thermal efficiency of the plant are to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis (b) Using the data from the problem statement, the enthalpies at various states are

$$h_1 = h_f @ 20 \text{ kPa} = 251 \text{ kJ/kg}$$

$$\nu_1 = \nu_f @ 20 \text{ kPa} = 0.00102 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{p,\text{in}} &= \nu_1 (P_2 - P_1) \\ &= (0.00102 \text{ m}^3/\text{kg})(5000 - 20 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 5.1 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 251 + 5.1 = 256.1 \text{ kJ/kg}$$

Also,

$$h_3 = h_{11} = h_f @ 245 \text{ kPa} = 533 \text{ kJ/kg}$$

$$h_{12} = h_{11} \quad (\text{throttle valve operation})$$

$$h_4 = h_9 = h_f @ 1400 \text{ kPa} = 830 \text{ kJ/kg}$$

$$h_{10} = h_9 \quad (\text{throttle valve operation})$$

An energy balance on the closed feedwater heater gives

$$1h_2 + zh_7 + yh_{10} = 1h_3 + (y+z)h_{11}$$

where z is the fraction of steam extracted from the low-pressure turbine. Solving for z ,

$$z = \frac{(h_3 - h_2) + y(h_{11} - h_{10})}{h_7 - h_{11}} = \frac{(533 - 256.1) + (0.1446)(533 - 830)}{2918 - 533} = \mathbf{0.09810}$$

(c) An energy balance on the condenser gives

$$\dot{m}_8 h_8 + \dot{m}_w h_{w1} + \dot{m}_{12} h_{12} = \dot{m}_1 h_1 + \dot{m}_w h_{w2}$$

$$\dot{m}_w (h_{w2} - h_{w1}) = \dot{m}_8 h_8 + \dot{m}_{12} h_{12} - \dot{m}_1 h_1$$

Solving for the mass flow rate of cooling water, and substituting with correct units,

$$\begin{aligned} \dot{m}_w &= \frac{\dot{m}_5 [(1-y-z)h_8 + (y+z)h_{12} - 1h_1]}{c_{pw} \Delta T_w} \\ &= \frac{(75) [(1 - 0.1446 - 0.09810)(2477) + (0.1446 + 0.09810)(533) - 1(251)]}{(4.18)(10)} \\ &= \mathbf{3147 \text{ kg/s}} \end{aligned}$$

(d) The work output from the turbines is

$$\begin{aligned} w_{T,\text{out}} &= h_5 - yh_6 - zh_7 - (1-y-z)h_8 \\ &= 3900 - (0.1446)(3406) - (0.09810)(2918) - (1 - 0.1446 - 0.09810)(2477) \\ &= 1245.4 \text{ kJ/kg} \end{aligned}$$

The net work output from the cycle is

$$\begin{aligned} w_{\text{net}} &= w_{T,\text{out}} - w_{P,\text{in}} \\ &= 1245.4 - 5.1 = 1240.3 \text{ kJ/kg} \end{aligned}$$

The net power output is

$$\dot{W}_{\text{net}} = \dot{m} w_{\text{net}} = (75 \text{ kg/s})(1240.3 \text{ kJ/kg}) = 93,024 \text{ kW} = \mathbf{93.0 \text{ MW}}$$

The rate of heat input in the boiler is

$$\dot{Q}_{\text{in}} = \dot{m}(h_5 - h_4) = (75 \text{ kg/s})(3900 - 830) \text{ kJ/kg} = 230,250 \text{ kW}$$

The thermal efficiency is then

$$\eta_{\text{th}} = \frac{\dot{W}_{\text{net}}}{\dot{Q}_{\text{in}}} = \frac{93,024 \text{ kW}}{230,250 \text{ kW}} = 0.404 = \mathbf{40.4\%}$$

Second-Law Analysis of Vapor Power Cycles

10-58 The exergy destructions associated with each of the processes of the Rankine cycle described in Prob. 10-12 are to be determined for the specified source and sink temperatures.

Assumptions **1** Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis From Problem 10-12,

$$s_1 = s_2 = s_f @ 50 \text{ kPa} = 1.0912 \text{ kJ/kg} \cdot \text{K}$$

$$s_3 = s_4 = 6.5412 \text{ kJ/kg} \cdot \text{K}$$

$$q_{in} = 2650.72 \text{ kJ/kg}$$

$$q_{out} = 1931.8 \text{ kJ/kg}$$

Processes 1-2 and 3-4 are isentropic. Thus, $i_{12} = 0$ and $i_{34} = 0$. Also,

$$x_{\text{destroyed}23} = T_0 \left(s_3 - s_2 + \frac{q_{R,23}}{T_R} \right) = (290 \text{ K}) \left(6.5412 - 1.0912 + \frac{-2650.8 \text{ kJ/kg}}{1500 \text{ K}} \right) = \mathbf{1068 \text{ kJ/kg}}$$

$$x_{\text{destroyed}41} = T_0 \left(s_1 - s_4 + \frac{q_{R,41}}{T_R} \right) = (290 \text{ K}) \left(1.0912 - 6.5412 + \frac{1931.8 \text{ kJ/kg}}{290 \text{ K}} \right) = \mathbf{351.3 \text{ kJ/kg}}$$

10-59 The exergy destructions associated with each of the processes of the Rankine cycle described in Prob. 10-16 are to be determined for the specified source and sink temperatures.

Assumptions **1** Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis From Problem 10-16,

$$s_1 = s_2 = s_f @ 10 \text{ kPa} = 0.6492 \text{ kJ/kg} \cdot \text{K}$$

$$s_3 = s_4 = 6.5995 \text{ kJ/kg} \cdot \text{K}$$

$$q_{in} = 3173.2 \text{ kJ/kg}$$

$$q_{out} = 1897.9 \text{ kJ/kg}$$

Processes 1-2 and 3-4 are isentropic. Thus, $i_{12} = 0$ and $i_{34} = 0$. Also,

$$x_{\text{destroyed}23} = T_0 \left(s_3 - s_2 + \frac{q_{R,23}}{T_R} \right) = (290 \text{ K}) \left(6.5995 - 0.6492 + \frac{-3173.2 \text{ kJ/kg}}{1500 \text{ K}} \right) = \mathbf{1112.1 \text{ kJ/kg}}$$

$$x_{\text{destroyed}41} = T_0 \left(s_1 - s_4 + \frac{q_{R,41}}{T_R} \right) = (290 \text{ K}) \left(0.6492 - 6.5995 + \frac{1897.9 \text{ kJ/kg}}{290 \text{ K}} \right) = \mathbf{172.3 \text{ kJ/kg}}$$

10-60 The exergy destructions associated with each of the processes of the reheat Rankine cycle described in Prob. 10-31 are to be determined for the specified source and sink temperatures.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From Problem 10-31,

$$s_1 = s_2 = s_{f@20\text{kPa}} = 0.8320 \text{ kJ/kg} \cdot \text{K}$$

$$s_3 = s_4 = 6.5432 \text{ kJ/kg} \cdot \text{K}$$

$$s_5 = s_6 = 7.1292 \text{ kJ/kg} \cdot \text{K}$$

$$q_{23,\text{in}} = 3178.3 - 257.50 = 2920.8 \text{ kJ/kg}$$

$$q_{45,\text{in}} = 3248.4 - 2901.0 = 347.3 \text{ kJ/kg}$$

$$q_{\text{out}} = h_6 - h_1 = 2349.7 - 251.42 = 2098.3 \text{ kJ/kg}$$

Processes 1-2, 3-4, and 5-6 are isentropic. Thus, $i_{12} = i_{34} = i_{56} = 0$. Also,

$$x_{\text{destroyed}23} = T_0 \left(s_3 - s_2 + \frac{q_{R,23}}{T_R} \right) = (295 \text{ K}) \left(6.5432 - 0.8320 + \frac{-2920.8 \text{ kJ/kg}}{1500 \text{ K}} \right) = \mathbf{1110 \text{ kJ/kg}}$$

$$x_{\text{destroyed}45} = T_0 \left(s_5 - s_4 + \frac{q_{R,45}}{T_R} \right) = (295 \text{ K}) \left(7.1292 - 6.5432 + \frac{-347.3 \text{ kJ/kg}}{1500 \text{ K}} \right) = \mathbf{104.6 \text{ kJ/kg}}$$

$$x_{\text{destroyed}61} = T_0 \left(s_1 - s_6 + \frac{q_{R,61}}{T_R} \right) = (295 \text{ K}) \left(0.8320 - 7.1292 + \frac{2098.3 \text{ kJ/kg}}{295 \text{ K}} \right) = \mathbf{240.6 \text{ kJ/kg}}$$

10-61 Problem 10-60 is reconsidered. The problem is to be solved by the diagram window data entry feature of EES by including the effects of the turbine and pump efficiencies. Also, the T - s diagram is to be plotted.

Analysis The problem is solved using EES, and the solution is given below.

```

10-62 The exergy destruction associated with the heat addition process and the expansion process in Prob. 10-37 are to be determined for the specified source and sink temperatures. The exergy of the steam at the boiler exit is also to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis From Problem 10-37,

$$\begin{aligned}s_1 &= s_2 = s_f @ 10 \text{ kPa} = 0.6492 \text{ kJ/kg} \cdot \text{K} \\s_3 &= 6.5995 \text{ kJ/kg} \cdot \text{K} \\s_4 &= 6.8464 \text{ kJ/kg} \cdot \text{K} \quad (P_4 = 1 \text{ MPa}, h_4 = 2902.0 \text{ kJ/kg}) \\s_5 &= 7.7642 \text{ kJ/kg} \cdot \text{K} \\s_6 &= 8.3870 \text{ kJ/kg} \cdot \text{K} \quad (P_6 = 10 \text{ kPa}, h_6 = 2664.8 \text{ kJ/kg}) \\h_3 &= 3375.1 \text{ kJ/kg} \\q_{\text{in}} &= 3749.8 \text{ kJ/kg}\end{aligned}$$

The exergy destruction associated with the combined pumping and the heat addition processes is

$$\begin{aligned}x_{\text{destroyed}} &= T_0 \left(s_3 - s_1 + s_5 - s_4 + \frac{q_{R,15}}{T_R} \right) \\&= (285 \text{ K}) \left(6.5995 - 0.6492 + 7.7642 - 6.8464 + \frac{-3749.8 \text{ kJ/kg}}{1600 \text{ K}} \right) \\&= 1289.5 \text{ kJ/kg}\end{aligned}$$

The exergy destruction associated with the pumping process is

$$x_{\text{destroyed}12} \cong w_{p,a} - w_{p,s} = w_{p,a} - v\Delta P = 10.62 - 10.09 = 0.53 \text{ kJ/kg}$$

Thus,

$$x_{\text{destroyed,heating}} = x_{\text{destroyed}} - x_{\text{destroyed}12} = 1289.5 - 0.5 = \mathbf{1289 \text{ kJ/kg}}$$

The exergy destruction associated with the expansion process is

$$\begin{aligned}x_{\text{destroyed}34} &= T_0 \left((s_4 - s_3) + (s_6 - s_5) + \frac{q_{R,36}}{T_R} \right) \\&= (285 \text{ K}) (6.8464 - 6.5995 + 8.3870 - 7.7642) \text{ kJ/kg} \cdot \text{K} \\&= \mathbf{247.9 \text{ kJ/kg}}\end{aligned}$$

The exergy of the steam at the boiler exit is determined from

$$\begin{aligned}\psi_3 &= (h_3 - h_0) - T_0 (s_3 - s_0) + \frac{V_3^2}{2} + qz_3 \\&= (h_3 - h_0) - T_0 (s_3 - s_0)\end{aligned}$$

where

$$\begin{aligned}h_0 &= h @ (285 \text{ K}, 100 \text{ kPa}) \cong h_f @ 285 \text{ K} = 50.51 \text{ kJ/kg} \\s_0 &= s @ (285 \text{ K}, 100 \text{ kPa}) \cong s_f @ 285 \text{ K} = 0.1806 \text{ kJ/kg} \cdot \text{K}\end{aligned}$$

Thus,

$$\psi_3 = (3375.1 - 50.51) \text{ kJ/kg} - (285 \text{ K}) (6.5995 - 0.1806) \text{ kJ/kg} \cdot \text{K} = \mathbf{1495 \text{ kJ/kg}}$$

10-63 The exergy destruction associated with the regenerative cycle described in Prob. 10-45 is to be determined for the specified source and sink temperatures.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From Problem 10-45, $q_{\text{in}} = 2692.2 \text{ kJ/kg}$ and $q_{\text{out}} = 1675.7 \text{ kJ/kg}$. Then the exergy destruction associated with this regenerative cycle is

$$x_{\text{destroyedcycle}} = T_0 \left(\frac{q_{\text{out}}}{T_L} - \frac{q_{\text{in}}}{T_H} \right) = (290 \text{ K}) \left(\frac{1675.7 \text{ kJ/kg}}{290 \text{ K}} - \frac{2692.2 \text{ kJ/kg}}{1500 \text{ K}} \right) = \mathbf{1155 \text{ kJ/kg}}$$

10-64 The exergy destruction associated with the reheating and regeneration processes described in Prob. 10-55 are to be determined for the specified source and sink temperatures.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From Problem 10-55 and the steam tables,

$$y = 0.2016$$

$$s_3 = s_{f@0.8\text{MPa}} = 2.0457 \text{ kJ/kg} \cdot \text{K}$$

$$s_5 = s_6 = 6.7585 \text{ kJ/kg} \cdot \text{K}$$

$$s_7 = 7.8692 \text{ kJ/kg} \cdot \text{K}$$

$$s_1 = s_2 = s_{f@10\text{kPa}} = 0.6492 \text{ kJ/kg} \cdot \text{K}$$

$$q_{\text{reheat}} = h_7 - h_6 = 3481.3 - 2812.7 = 668.6 \text{ kJ/kg}$$

Then the exergy destruction associated with reheat and regeneration processes are

$$\begin{aligned} x_{\text{destroyedreheat}} &= T_0 \left(s_7 - s_6 + \frac{q_{R,67}}{T_R} \right) \\ &= (290 \text{ K}) \left(7.8692 - 6.7585 + \frac{-668.6 \text{ kJ/kg}}{1800 \text{ K}} \right) \\ &= \mathbf{214.3 \text{ kJ/kg}} \end{aligned}$$

$$\begin{aligned} x_{\text{destroyedregen}} &= T_0 s_{\text{gen}} = T_0 \left(\sum m_e s_e - \sum m_i s_i + \frac{q_{\text{surr}}}{T_0} \right) = T_0 (s_3 - y s_6 - (1-y) s_2) \\ &= (290 \text{ K}) [2.0457 - (0.2016)(6.7585) - (1-0.2016)(0.6492)] \\ &= \mathbf{47.8 \text{ kJ/kg}} \end{aligned}$$

10-65 A single-flash geothermal power plant uses hot geothermal water at 230°C as the heat source. The power output from the turbine, the thermal efficiency of the plant, the exergy of the geothermal liquid at the exit of the flash chamber, and the exergy destructions and exergy efficiencies for the flash chamber, the turbine, and the entire plant are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) We use properties of water for geothermal water (Tables A-4, A-5, and A-6)

$$\left. \begin{aligned} T_1 = 230^\circ\text{C} \\ x_1 = 0 \end{aligned} \right\} \begin{aligned} h_1 = 990.14 \text{ kJ/kg} \\ s_1 = 2.6100 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

$$\left. \begin{aligned} P_2 = 500 \text{ kPa} \\ h_2 = h_1 = 990.14 \text{ kJ/kg} \end{aligned} \right\} \begin{aligned} x_2 = 0.1661 \\ s_2 = 2.6841 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

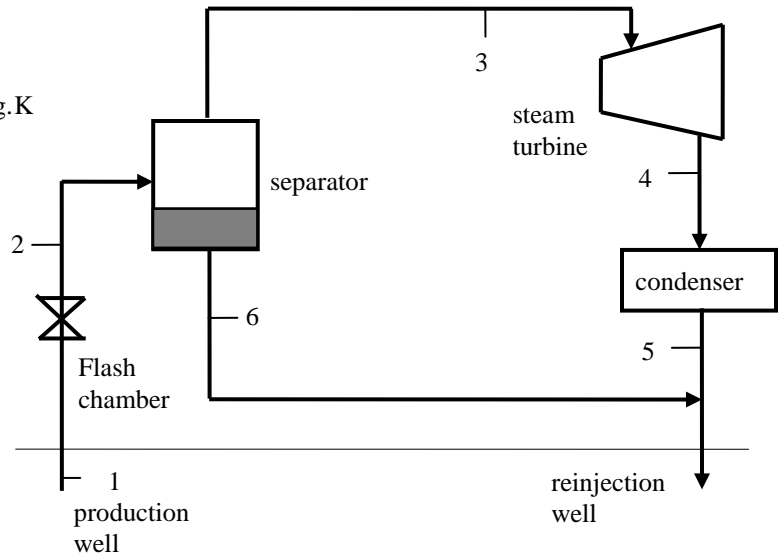

$$\begin{aligned} \dot{m}_3 &= x_2 \dot{m}_1 \\ &= (0.1661)(230 \text{ kg/s}) \\ &= 38.19 \text{ kg/s} \end{aligned}$$

$$\left. \begin{aligned} P_3 = 500 \text{ kPa} \\ x_3 = 1 \end{aligned} \right\} \begin{aligned} h_3 = 2748.1 \text{ kJ/kg} \\ s_3 = 6.8207 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

$$\left. \begin{aligned} P_4 = 10 \text{ kPa} \\ x_4 = 0.95 \end{aligned} \right\} \begin{aligned} h_4 = 2464.3 \text{ kJ/kg} \\ s_4 = 7.7739 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

$$\left. \begin{aligned} P_6 = 500 \text{ kPa} \\ x_6 = 0 \end{aligned} \right\} \begin{aligned} h_6 = 640.09 \text{ kJ/kg} \\ s_6 = 1.8604 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

$$\dot{m}_6 = \dot{m}_1 - \dot{m}_3 = 230 - 38.19 = 191.81 \text{ kg/s}$$

The power output from the turbine is

$$\dot{W}_T = \dot{m}_3 (h_3 - h_4) = (38.19 \text{ kg/s})(2748.1 - 2464.3) \text{ kJ/kg} = \mathbf{10,842 \text{ kW}}$$

We use saturated liquid state at the standard temperature for dead state properties

$$\left. \begin{aligned} T_0 = 25^\circ\text{C} \\ x_0 = 0 \end{aligned} \right\} \begin{aligned} h_0 = 104.83 \text{ kJ/kg} \\ s_0 = 0.3672 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

$$\dot{E}_{\text{in}} = \dot{m}_1 (h_1 - h_0) = (230 \text{ kg/s})(990.14 - 104.83) \text{ kJ/kg} = 203,622 \text{ kW}$$

$$\eta_{\text{th}} = \frac{\dot{W}_{T,\text{out}}}{\dot{E}_{\text{in}}} = \frac{10,842}{203,622} = 0.0532 = \mathbf{5.3\%}$$

(b) The specific exergies at various states are

$$\psi_1 = h_1 - h_0 - T_0 (s_1 - s_0) = (990.14 - 104.83) \text{ kJ/kg} - (298 \text{ K})(2.6100 - 0.3672) \text{ kJ/kg}\cdot\text{K} = 216.53 \text{ kJ/kg}$$

$$\psi_2 = h_2 - h_0 - T_0 (s_2 - s_0) = (990.14 - 104.83) \text{ kJ/kg} - (298 \text{ K})(2.6841 - 0.3672) \text{ kJ/kg}\cdot\text{K} = 194.44 \text{ kJ/kg}$$

$$\psi_3 = h_3 - h_0 - T_0 (s_3 - s_0) = (2748.1 - 104.83) \text{ kJ/kg} - (298 \text{ K})(6.8207 - 0.3672) \text{ kJ/kg}\cdot\text{K} = 719.10 \text{ kJ/kg}$$

$$\psi_4 = h_4 - h_0 - T_0 (s_4 - s_0) = (2464.3 - 104.83) \text{ kJ/kg} - (298 \text{ K})(7.7739 - 0.3672) \text{ kJ/kg}\cdot\text{K} = 151.05 \text{ kJ/kg}$$

$$\psi_6 = h_6 - h_0 - T_0 (s_6 - s_0) = (640.09 - 104.83) \text{ kJ/kg} - (298 \text{ K})(1.8604 - 0.3672) \text{ kJ/kg}\cdot\text{K} = 89.97 \text{ kJ/kg}$$

The exergy of geothermal water at state 6 is

$$\dot{X}_6 = \dot{m}_6 \psi_6 = (191.81 \text{ kg/s})(89.97 \text{ kJ/kg}) = \mathbf{17,257 \text{ kW}}$$

(c) Turbine:

$$\dot{X}_{\text{dest},T} = \dot{m}_3 (\psi_3 - \psi_4) - \dot{W}_T = (38.19 \text{ kg/s})(719.10 - 151.05) \text{ kJ/kg} - 10,842 \text{ kW} = \mathbf{10,854 \text{ kW}}$$

$$\eta_{II,T} = \frac{\dot{W}_T}{\dot{m}_3(\psi_3 - \psi_4)} = \frac{10,842 \text{ kW}}{(38.19 \text{ kg/s})(719.10 - 151.05) \text{ kJ/kg}} = 0.500 = \mathbf{50.0\%}$$

(d) Plant:

$$\dot{X}_{\text{in,Plant}} = \dot{m}_1\psi_1 = (230 \text{ kg/s})(216.53 \text{ kJ/kg}) = 49,802 \text{ kW}$$

$$\dot{X}_{\text{dest,Plant}} = \dot{X}_{\text{in,Plant}} - \dot{W}_T = 49,802 - 10,842 = \mathbf{38,960 \text{ kW}}$$

$$\eta_{II,\text{Plant}} = \frac{\dot{W}_T}{\dot{X}_{\text{in,Plant}}} = \frac{10,842 \text{ kW}}{49,802 \text{ kW}} = 0.2177 = \mathbf{21.8\%}$$

Cogeneration

10-66C The utilization factor of a cogeneration plant is the ratio of the energy utilized for a useful purpose to the total energy supplied. It could be unity for a plant that does not produce any power.

10-67C No. A cogeneration plant may involve throttling, friction, and heat transfer through a finite temperature difference, and still have a utilization factor of unity.

10-68C Yes, if the cycle involves no irreversibilities such as throttling, friction, and heat transfer through a finite temperature difference.

10-69 A cogeneration plant is to generate power and process heat. Part of the steam extracted from the turbine at a relatively high pressure is used for process heating. The net power produced and the utilization factor of the plant are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 10 \text{ kPa} = 191.81 \text{ kJ/kg}$$

$$v_1 = v_f @ 10 \text{ kPa} = 0.00101 \text{ m}^3/\text{kg}$$

$$w_{pI, \text{in}} = v_1(P_2 - P_1) \\ = (0.00101 \text{ m}^3/\text{kg})(1200 - 10 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ = 1.20 \text{ kJ/kg}$$

$$h_2 = h_1 + w_{pI, \text{in}} = 191.81 + 1.20 = 193.01 \text{ kJ/kg}$$

$$h_3 = h_f @ 1.2 \text{ MPa} = 798.33 \text{ kJ/kg}$$

Mixing chamber:

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\text{no (steady)}}{=} 0 \longrightarrow \dot{E}_{\text{in}} = \dot{E}_{\text{out}} \\ \sum \dot{m}_i h_i = \sum \dot{m}_e h_e \longrightarrow \dot{m}_4 h_4 = \dot{m}_2 h_2 + \dot{m}_3 h_3$$

$$\text{or, } h_4 = \frac{\dot{m}_2 h_2 + \dot{m}_3 h_3}{\dot{m}_4} = \frac{(22.50)(192.41) + (7.50)(798.33)}{30} = 344.34 \text{ kJ/kg}$$

$$v_4 \cong v_f @ h_f = 344.34 \text{ kJ/kg} = 0.001031 \text{ m}^3/\text{kg}$$

$$w_{pII, \text{in}} = v_4(P_5 - P_4) \\ = (0.001031 \text{ m}^3/\text{kg})(4000 - 1200 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ = 2.89 \text{ kJ/kg}$$

$$h_5 = h_4 + w_{pII, \text{in}} = 344.34 + 2.89 = 347.22 \text{ kJ/kg}$$

$$P_6 = 4 \text{ MPa} \left. \begin{array}{l} h_6 = 3446.0 \text{ kJ/kg} \\ T_6 = 500^\circ\text{C} \end{array} \right\} s_6 = 7.0922 \text{ kJ/kg} \cdot \text{K}$$

$$P_7 = 1.2 \text{ MPa} \left. \begin{array}{l} h_7 = 3080.4 \text{ kJ/kg} \\ s_7 = s_6 \end{array} \right\}$$

$$P_8 = 10 \text{ kPa} \left. \begin{array}{l} x_8 = \frac{s_8 - s_f}{s_{fg}} = \frac{7.0922 - 0.6492}{7.4996} = 0.8591 \\ s_8 = s_6 \end{array} \right\}$$

$$h_8 = h_f + x_8 h_{fg} = 191.81 + (0.8591)(2392.1) = 2246.9 \text{ kJ/kg}$$

Then,

$$\dot{W}_{T, \text{out}} = \dot{m}_6(h_6 - h_7) + \dot{m}_8(h_7 - h_8) \\ = (55 \text{ kg/s})(3446.0 - 3080.4) \text{ kJ/kg} + (0.75 \times 55 \text{ kg/s})(3080.4 - 2246.9) \text{ kJ/kg} = 54,494 \text{ kW}$$

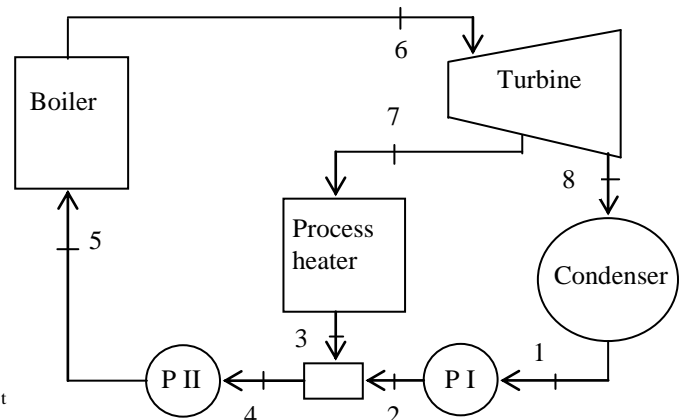

$$\dot{W}_{p, \text{in}} = \dot{m}_1 w_{pI, \text{in}} + \dot{m}_4 w_{pII, \text{in}} = (0.75 \times 55 \text{ kg/s})(1.20 \text{ kJ/kg}) + (55 \text{ kg/s})(2.89 \text{ kJ/kg}) = 208.3 \text{ kW}$$

$$\dot{W}_{\text{net}} = \dot{W}_{T, \text{out}} - \dot{W}_{p, \text{in}} = 54,494 - 208.3 = \mathbf{54,285 \text{ kW}}$$

$$\text{Also, } \dot{Q}_{\text{process}} = \dot{m}_7(h_7 - h_3) = (0.25 \times 55 \text{ kg/s})(3080.4 - 798.33) \text{ kJ/kg} = 31,379 \text{ kW}$$

$$\dot{Q}_{\text{in}} = \dot{m}_5(h_6 - h_5) = (55 \text{ kg/s})(3446.0 - 347.22) = 170,435 \text{ kW}$$

$$\text{and } \varepsilon_u = \frac{\dot{W}_{\text{net}} + \dot{Q}_{\text{process}}}{\dot{Q}_{\text{in}}} = \frac{54,285 + 31,379}{170,435} = 0.5026 = \mathbf{50.3\%}$$

10-70E A large food-processing plant requires steam at a relatively high pressure, which is extracted from the turbine of a cogeneration plant. The rate of heat transfer to the boiler and the power output of the cogeneration plant are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) From the steam tables (Tables A-4E, A-5E, and A-6E),

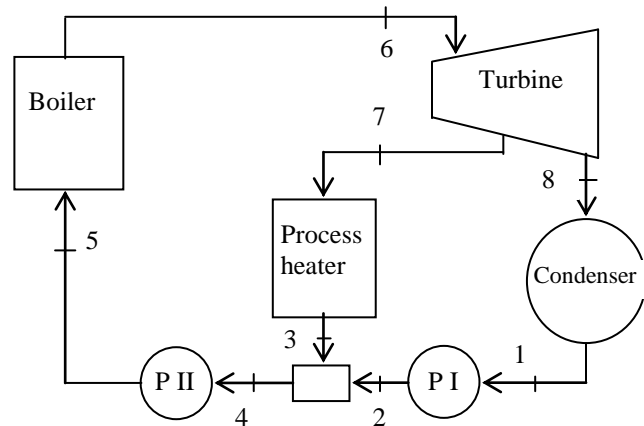

$$h_1 = h_f @ 2 \text{ psia} = 94.02 \text{ Btu/lbm}$$

$$\nu_1 = \nu_f @ 2 \text{ psia} = 0.01623 \text{ ft}^3/\text{lbm}$$

$$\begin{aligned} w_{pI, \text{in}} &= \nu_1 (P_2 - P_1) / \eta_p \\ &= \frac{1}{0.86} (0.01623 \text{ ft}^3/\text{lbm})(140 - 2) \text{ psia} \\ &\quad \times \left(\frac{1 \text{ Btu}}{5.4039 \text{ psia} \cdot \text{ft}^3} \right) \\ &= 0.48 \text{ Btu/lbm} \end{aligned}$$

$$h_2 = h_1 + w_{pI, \text{in}} = 94.02 + 0.48 = 94.50 \text{ Btu/lbm}$$

$$h_3 = h_f @ 140 \text{ psia} = 324.92 \text{ Btu/lbm}$$

Mixing chamber:

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\approx 0 \text{ (steady)}}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \quad \longrightarrow \quad \dot{m}_4 h_4 = \dot{m}_2 h_2 + \dot{m}_3 h_3$$

or,

$$h_4 = \frac{\dot{m}_2 h_2 + \dot{m}_3 h_3}{\dot{m}_4} = \frac{(8.5)(94.50) + (1.5)(324.92)}{10} = 129.07 \text{ Btu/lbm}$$

$$\nu_4 \cong \nu_f @ h_f = 129.07 \text{ Btu/lbm} = 0.01640 \text{ ft}^3/\text{lbm}$$

$$\begin{aligned} w_{pII, \text{in}} &= \nu_4 (P_5 - P_4) / \eta_p \\ &= (0.01640 \text{ ft}^3/\text{lbm})(800 - 140 \text{ psia}) \left(\frac{1 \text{ Btu}}{5.4039 \text{ psia} \cdot \text{ft}^3} \right) / (0.86) \\ &= 2.33 \text{ Btu/lbm} \end{aligned}$$

$$h_5 = h_4 + w_{pII, \text{in}} = 129.07 + 2.33 = 131.39 \text{ Btu/lbm}$$

$$\left. \begin{aligned} P_6 &= 800 \text{ psia} \\ T_6 &= 1000^\circ\text{F} \end{aligned} \right\} \begin{aligned} h_6 &= 1512.2 \text{ Btu/lbm} \\ s_6 &= 1.6812 \text{ Btu/lbm} \cdot \text{R} \end{aligned}$$

$$\left. \begin{aligned} P_{7s} &= 140 \text{ psia} \\ s_{7s} &= s_6 \end{aligned} \right\} h_{7s} = 1287.5 \text{ Btu/lbm}$$

$$\left. \begin{aligned} P_{8s} &= 2 \text{ psia} \\ s_{8s} &= s_6 \end{aligned} \right\} \begin{aligned} x_{8s} &= \frac{s_{8s} - s_f}{s_{fg}} = \frac{1.6812 - 0.17499}{1.74444} = 0.8634 \\ h_{8s} &= h_f + x_{8s} h_{fg} = 94.02 + (0.8634)(1021.7) = 976.21 \text{ Btu/lbm} \end{aligned}$$

Then, $\dot{Q}_{\text{in}} = \dot{m}_5 (h_6 - h_5) = (10 \text{ lbm/s})(1512.2 - 131.39) \text{ Btu/lbm} = \mathbf{13,810 \text{ Btu/s}}$

(b) $\dot{W}_{T, \text{out}} = \eta_T \dot{W}_{T, s} = \eta_T [\dot{m}_6 (h_6 - h_{7s}) + \dot{m}_8 (h_{7s} - h_{8s})]$
 $= (0.86) [(10 \text{ lbm/s})(1512.2 - 1287.5) \text{ Btu/lbm} + (1.5 \text{ lbm/s})(1287.5 - 976.21) \text{ Btu/lbm}]$
 $= 4208 \text{ Btu/s} = \mathbf{4440 \text{ kW}}$

10-71 A cogeneration plant has two modes of operation. In the first mode, all the steam leaving the turbine at a relatively high pressure is routed to the process heater. In the second mode, 60 percent of the steam is routed to the process heater and remaining is expanded to the condenser pressure. The power produced and the rate at which process heat is supplied in the first mode, and the power produced and the rate of process heat supplied in the second mode are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 20 \text{ kPa} = 251.42 \text{ kJ/kg}$$

$$\nu_1 = \nu_f @ 20 \text{ kPa} = 0.001017 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{pI,in} &= \nu_1 (P_2 - P_1) \\ &= (0.001017 \text{ m}^3/\text{kg})(10,000 - 20 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 10.15 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{pI,in} = 251.42 + 10.15 = 261.57 \text{ kJ/kg}$$

$$h_3 = h_f @ 0.5 \text{ MPa} = 640.09 \text{ kJ/kg}$$

$$\nu_3 = \nu_f @ 0.5 \text{ MPa} = 0.001093 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{pII,in} &= \nu_3 (P_4 - P_3) \\ &= (0.001093 \text{ m}^3/\text{kg})(10,000 - 500 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 10.38 \text{ kJ/kg} \end{aligned}$$

$$h_4 = h_3 + w_{pII,in} = 640.09 + 10.38 = 650.47 \text{ kJ/kg}$$

Mixing chamber:

$$\begin{aligned} \dot{E}_{in} - \dot{E}_{out} &= \Delta \dot{E}_{system} \stackrel{\approx 0 \text{ (steady)}}{=} 0 \rightarrow \dot{E}_{in} = \dot{E}_{out} \\ \sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \rightarrow \dot{m}_5 h_5 = \dot{m}_2 h_2 + \dot{m}_4 h_4 \end{aligned}$$

$$\text{or, } h_5 = \frac{\dot{m}_2 h_2 + \dot{m}_4 h_4}{\dot{m}_5} = \frac{(2)(261.57) + (3)(650.47)}{5} = 494.91 \text{ kJ/kg}$$

$$\left. \begin{aligned} P_6 &= 10 \text{ MPa} \\ T_6 &= 450^\circ\text{C} \end{aligned} \right\} \begin{aligned} h_6 &= 3242.4 \text{ kJ/kg} \\ s_6 &= 6.4219 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

$$\left. \begin{aligned} P_7 &= 0.5 \text{ MPa} \\ s_7 &= s_6 \end{aligned} \right\} \begin{aligned} x_7 &= \frac{s_7 - s_f}{s_{fg}} = \frac{6.4219 - 1.8604}{4.9603} = 0.9196 \\ h_7 &= h_f + x_7 h_{fg} = 640.09 + (0.9196)(2108.0) = 2578.6 \text{ kJ/kg} \end{aligned}$$

$$\left. \begin{aligned} P_8 &= 20 \text{ kPa} \\ s_8 &= s_6 \end{aligned} \right\} \begin{aligned} x_8 &= \frac{s_8 - s_f}{s_{fg}} = \frac{6.4219 - 0.8320}{7.0752} = 0.7901 \\ h_8 &= h_f + x_8 h_{fg} = 251.42 + (0.7901)(2357.5) = 2114.0 \text{ kJ/kg} \end{aligned}$$

When the entire steam is routed to the process heater,

$$\dot{W}_{T,out} = \dot{m}_6 (h_6 - h_7) = (5 \text{ kg/s})(3242.4 - 2578.6) \text{ kJ/kg} = \mathbf{3319 \text{ kW}}$$

$$\dot{Q}_{process} = \dot{m}_7 (h_7 - h_3) = (5 \text{ kg/s})(2578.6 - 640.09) \text{ kJ/kg} = \mathbf{9693 \text{ kW}}$$

(b) When only 60% of the steam is routed to the process heater,

$$\begin{aligned} \dot{W}_{T,out} &= \dot{m}_6 (h_6 - h_7) + \dot{m}_8 (h_7 - h_8) \\ &= (5 \text{ kg/s})(3242.4 - 2578.6) \text{ kJ/kg} + (2 \text{ kg/s})(2578.6 - 2114.0) \text{ kJ/kg} = \mathbf{4248 \text{ kW}} \end{aligned}$$

$$\dot{Q}_{process} = \dot{m}_7 (h_7 - h_3) = (3 \text{ kg/s})(2578.6 - 640.09) \text{ kJ/kg} = \mathbf{5816 \text{ kW}}$$

10-72 A cogeneration plant modified with regeneration is to generate power and process heat. The mass flow rate of steam through the boiler for a net power output of 25 MW is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 10 \text{ kPa} = 191.81 \text{ kJ/kg}$$

$$v_1 = v_f @ 10 \text{ kPa} = 0.00101 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{pI,in} &= v_1(P_2 - P_1) \\ &= (0.00101 \text{ m}^3/\text{kg})(1600 - 10 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 1.61 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{pI,in} = 191.81 + 1.61 = 193.41 \text{ kJ/kg}$$

$$h_3 = h_4 = h_9 = h_f @ 1.6 \text{ MPa} = 858.44 \text{ kJ/kg}$$

$$v_4 = v_f @ 1.6 \text{ MPa} = 0.001159 \text{ m}^3/\text{kg}$$

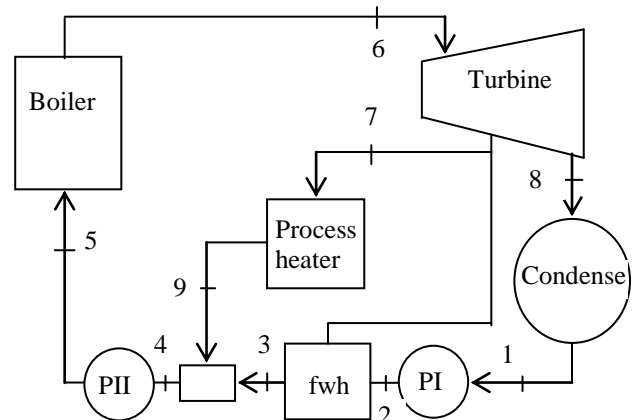

$$\begin{aligned} w_{pII,in} &= v_4(P_5 - P_4) \\ &= (0.001159 \text{ m}^3/\text{kg})(9000 - 400 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 8.57 \text{ kJ/kg} \end{aligned}$$

$$h_5 = h_4 + w_{pII,in} = 858.44 + 8.57 = 867.02 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_6 = 9 \text{ MPa} \\ T_6 = 400^\circ\text{C} \end{array} \right\} \begin{array}{l} h_6 = 3118.8 \text{ kJ/kg} \\ s_6 = 6.2876 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_7 = 1.6 \text{ MPa} \\ s_7 = s_6 \end{array} \right\} \begin{array}{l} x_7 = \frac{s_7 - s_f}{s_{fg}} = \frac{6.2876 - 2.3435}{4.0765} = 0.9675 \\ h_7 = h_f + x_7 h_{fg} = 858.44 + (0.9675)(1934.4) = 2730.0 \text{ kJ/kg} \end{array}$$

$$\left. \begin{array}{l} P_8 = 10 \text{ kPa} \\ s_8 = s_6 \end{array} \right\} \begin{array}{l} x_8 = \frac{s_8 - s_f}{s_{fg}} = \frac{6.2876 - 0.6492}{7.4996} = 0.7518 \\ h_8 = h_f + x_8 h_{fg} = 191.81 + (0.7518)(2392.1) = 1990.2 \text{ kJ/kg} \end{array}$$

Then, per kg of steam flowing through the boiler, we have

$$\begin{aligned} w_{T,out} &= (h_6 - h_7) + (1 - y)(h_7 - h_8) \\ &= (3118.8 - 2730.0) \text{ kJ/kg} + (1 - 0.35)(2730.0 - 1990.2) \text{ kJ/kg} \\ &= 869.7 \text{ kJ/kg} \end{aligned}$$

$$\begin{aligned} w_{p,in} &= (1 - y)w_{pI,in} + w_{pII,in} \\ &= (1 - 0.35)(1.61 \text{ kJ/kg}) + (8.57 \text{ kJ/kg}) \\ &= 9.62 \text{ kJ/kg} \end{aligned}$$

$$w_{net} = w_{T,out} - w_{p,in} = 869.7 - 9.62 = 860.1 \text{ kJ/kg}$$

Thus,

$$\dot{m} = \frac{\dot{W}_{net}}{w_{net}} = \frac{25,000 \text{ kJ/s}}{860.1 \text{ kJ/kg}} = \mathbf{29.1 \text{ kg/s}}$$

10-73 Problem 10-72 is reconsidered. The effect of the extraction pressure for removing steam from the turbine to be used for the process heater and open feedwater heater on the required mass flow rate is to be investigated.

Analysis The problem is solved using EES, and the solution is given below.

10-74E A cogeneration plant is to generate power while meeting the process steam requirements for a certain industrial application. The net power produced, the rate of process heat supply, and the utilization factor of this plant are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) From the steam tables (Tables A-4E, A-5E, and A-6E),

$$h_1 \cong h_f @ 240^\circ\text{F} = 208.49 \text{ Btu/lbm}$$

$$h_2 \cong h_1$$

$$P_3 = 600 \text{ psia} \left. \vphantom{P_3} \right\} h_3 = 1321.3 \text{ Btu/lbm}$$

$$T_3 = 650^\circ\text{F} \left. \vphantom{T_3} \right\} s_3 = s_5 = s_7 = 1.5614 \text{ Btu/lbm} \cdot \text{R}$$

$$h_3 = h_4 = h_5 = h_6$$

$$P_7 = 120 \text{ psia} \left. \vphantom{P_7} \right\} h_7 = 1169.2 \text{ Btu/lbm}$$

$$s_7 = s_3$$

$$\begin{aligned} \dot{W}_{\text{net}} &= \dot{m}_5 (h_5 - h_7) \\ &= (2/3 \times 32 \text{ lbm/s})(1321.3 - 1169.2) \text{ Btu/lbm} \\ &= 3244 \text{ Btu/s} = \mathbf{3422 \text{ kW}} \end{aligned}$$

$$\begin{aligned} (b) \quad \dot{Q}_{\text{process}} &= \sum \dot{m}_i h_i - \sum \dot{m}_e h_e \\ &= \dot{m}_6 h_6 + \dot{m}_7 h_7 - \dot{m}_1 h_1 \\ &= (1/3 \times 32)(1321.3) + (2/3 \times 32)(1169.2) - (32)(208.49) \\ &= \mathbf{32,365 \text{ Btu/s}} \end{aligned}$$

$$(c) \quad \varepsilon_u = \mathbf{1} \text{ since all the energy is utilized.}$$

Combined Gas-Vapor Power Cycles

10-75C The energy source of the steam is the waste energy of the exhausted combustion gases.

10-76C Because the combined gas-steam cycle takes advantage of the desirable characteristics of the gas cycle at high temperature, and those of steam cycle at low temperature, and combines them. The result is a cycle that is more efficient than either cycle executed operated alone.

10-77 A combined gas-steam power cycle is considered. The topping cycle is a gas-turbine cycle and the bottoming cycle is a simple ideal Rankine cycle. The mass flow rate of the steam, the net power output, and the thermal efficiency of the combined cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2).

Analysis (a) The analysis of gas cycle yields

$$T_6 = T_5 \left(\frac{P_6}{P_5} \right)^{(k-1)/k} = (300 \text{ K})(16)^{0.4/1.4} = 662.5 \text{ K}$$

$$\dot{Q}_{\text{in}} = \dot{m}_{\text{air}}(h_7 - h_6) = \dot{m}_{\text{air}} c_p (T_7 - T_6) \\ = (14 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(1500 - 662.5) \text{ K} = 11,784 \text{ kW}$$

$$\dot{W}_{C,\text{gas}} = \dot{m}_{\text{air}}(h_6 - h_5) = \dot{m}_{\text{air}} c_p (T_6 - T_5) \\ = (14 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(662.5 - 300) \text{ K} = 5100 \text{ kW}$$

$$T_8 = T_7 \left(\frac{P_8}{P_7} \right)^{(k-1)/k} = (1500 \text{ K}) \left(\frac{1}{16} \right)^{0.4/1.4} = 679.3 \text{ K}$$

$$\dot{W}_{T,\text{gas}} = \dot{m}_{\text{air}}(h_7 - h_8) = \dot{m}_{\text{air}} c_p (T_7 - T_8) \\ = (14 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(1500 - 679.3) \text{ K} = 11,547 \text{ kW}$$

$$\dot{W}_{\text{net,gas}} = \dot{W}_{T,\text{gas}} - \dot{W}_{C,\text{gas}} = 11,547 - 5,100 = 6447 \text{ kW}$$

From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 15 \text{ kPa} = 225.94 \text{ kJ/kg}$$

$$v_1 = v_f @ 15 \text{ kPa} = 0.001014 \text{ m}^3/\text{kg}$$

$$w_{p,\text{lin}} = v_1(P_2 - P_1) = (0.001014 \text{ m}^3/\text{kg})(10,000 - 15 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa}\cdot\text{m}^3} \right) = 10.12 \text{ kJ/kg}$$

$$h_2 = h_1 + w_{p,\text{lin}} = 225.94 + 10.13 = 236.06 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 10 \text{ MPa} \\ T_3 = 400^\circ\text{C} \end{array} \right\} \begin{array}{l} h_3 = 3097.0 \text{ kJ/kg} \\ s_3 = 6.2141 \text{ kJ/kg}\cdot\text{K} \end{array}$$

$$\left. \begin{array}{l} P_4 = 15 \text{ kPa} \\ s_4 = s_3 \end{array} \right\} \begin{array}{l} x_4 = \frac{s_4 - s_f}{s_{fg}} = \frac{6.2141 - 0.7549}{7.2522} = 0.7528 \\ h_4 = h_f + x_4 h_{fg} = 225.94 + (0.7528)(2372.3) = 2011.8 \text{ kJ/kg} \end{array}$$

Noting that $\dot{Q} \cong \dot{W} \cong \Delta ke \cong \Delta pe \cong 0$ for the heat exchanger, the steady-flow energy balance equation yields

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\text{0 (steady)}}{=} 0 \longrightarrow \dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \longrightarrow \dot{m}_s (h_3 - h_2) = \dot{m}_{\text{air}} (h_8 - h_9)$$

$$\dot{m}_s = \frac{h_8 - h_9}{h_3 - h_2} \dot{m}_{\text{air}} = \frac{c_p (T_8 - T_9)}{h_3 - h_2} \dot{m}_{\text{air}} = \frac{(1.005 \text{ kJ/kg}\cdot\text{K})(679.3 - 420) \text{ K}}{(3097.0 - 236.06) \text{ kJ/kg}} (14 \text{ kg/s}) = 1.275 \text{ kg/s}$$

$$(b) \quad \dot{W}_{T,\text{steam}} = \dot{m}_s (h_3 - h_4) = (1.275 \text{ kg/s})(3097.0 - 2011.5) \text{ kJ/kg} = 1384 \text{ kW}$$

$$\dot{W}_{p,\text{steam}} = \dot{m}_s w_p = (1.275 \text{ kg/s})(10.12 \text{ kJ/kg}) = 12.9 \text{ kW}$$

$$\dot{W}_{\text{net,steam}} = \dot{W}_{T,\text{steam}} - \dot{W}_{p,\text{steam}} = 1384 - 12.9 = 1371 \text{ kW}$$

and $\dot{W}_{\text{net}} = \dot{W}_{\text{net,steam}} + \dot{W}_{\text{net,gas}} = 1371 + 6448 = \mathbf{7819 \text{ kW}}$

$$(c) \quad \eta_{\text{th}} = \frac{\dot{W}_{\text{net}}}{\dot{Q}_{\text{in}}} = \frac{7819 \text{ kW}}{11,784 \text{ kW}} = \mathbf{66.4\%}$$

10-78 A 450-MW combined gas-steam power plant is considered. The topping cycle is a gas-turbine cycle and the bottoming cycle is an ideal Rankine cycle with an open feedwater heater. The mass flow rate of air to steam, the required rate of heat input in the combustion chamber, and the thermal efficiency of the combined cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with variable specific heats.

Analysis (a) The analysis of gas cycle yields (Table A-17)

$$T_8 = 300 \text{ K} \longrightarrow h_8 = 300.19 \text{ kJ/kg}$$

$$P_{r_8} = 1.386$$

$$P_{r_9} = \frac{P_9}{P_8} P_{r_8} = (14)(1.386) = 19.40 \longrightarrow h_9 = 635.5 \text{ kJ/kg}$$

$$T_{10} = 1400 \text{ K} \longrightarrow h_{10} = 1515.42 \text{ kJ/kg}$$

$$P_{r_{10}} = 450.5$$

$$P_{r_{11}} = \frac{P_{11}}{P_{10}} P_{r_{10}} = \left(\frac{1}{14}\right)(450.5) = 32.18 \longrightarrow h_{11} = 735.8 \text{ kJ/kg}$$

$$T_{12} = 460 \text{ K} \longrightarrow h_{12} = 462.02 \text{ kJ/kg}$$

From the steam tables (Tables A-4, A-5, A-6),

$$h_1 = h_f @ 20 \text{ kPa} = 251.42 \text{ kJ/kg}$$

$$\nu_1 = \nu_f @ 20 \text{ kPa} = 0.001017 \text{ m}^3/\text{kg}$$

$$w_{pI, \text{in}} = \nu_1 (P_2 - P_1)$$

$$= (0.001017 \text{ m}^3/\text{kg})(600 - 20 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right)$$

$$= 0.59 \text{ kJ/kg}$$

$$h_2 = h_1 + w_{pI, \text{in}} = 251.42 + 0.59 = 252.01 \text{ kJ/kg}$$

$$h_3 = h_f @ 0.6 \text{ MPa} = 670.38 \text{ kJ/kg}$$

$$\nu_3 = \nu_f @ 0.6 \text{ MPa} = 0.001101 \text{ m}^3/\text{kg}$$

$$w_{pII, \text{in}} = \nu_3 (P_4 - P_3)$$

$$= (0.001101 \text{ m}^3/\text{kg})(8,000 - 600 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right)$$

$$= 8.15 \text{ kJ/kg}$$

$$h_4 = h_3 + w_{pII, \text{in}} = 670.38 + 8.15 = 678.53 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_5 = 8 \text{ MPa} \\ T_5 = 400^\circ\text{C} \end{array} \right\} \begin{array}{l} h_5 = 3139.4 \text{ kJ/kg} \\ s_5 = 6.3658 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_6 = 0.6 \text{ MPa} \\ s_6 = s_5 \end{array} \right\} \begin{array}{l} x_6 = \frac{s_6 - s_f}{s_{fg}} = \frac{6.3658 - 1.9308}{4.8285} = 0.9185 \\ h_6 = h_f + x_6 h_{fg} = 670.38 + (0.9185)(2085.8) = 2586.1 \text{ kJ/kg} \end{array}$$

$$\left. \begin{array}{l} P_7 = 20 \text{ kPa} \\ s_7 = s_5 \end{array} \right\} \begin{array}{l} x_7 = \frac{s_7 - s_f}{s_{fg}} = \frac{6.3658 - 0.8320}{7.0752} = 0.7821 \\ h_7 = h_f + x_7 h_{fg} = 251.42 + (0.7821)(2357.5) = 2095.2 \text{ kJ/kg} \end{array}$$

Noting that $\dot{Q} \cong \dot{W} \cong \Delta ke \cong \Delta pe \cong 0$ for the heat exchanger, the steady-flow energy balance equation yields

$$\begin{aligned}\dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \stackrel{\phi^0(\text{steady})}{=} 0 \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \longrightarrow \dot{m}_s (h_5 - h_4) = \dot{m}_{\text{air}} (h_{11} - h_{12}) \\ \frac{\dot{m}_{\text{air}}}{\dot{m}_s} &= \frac{h_5 - h_4}{h_{11} - h_{12}} = \frac{3139.4 - 678.53}{735.80 - 462.02} = \mathbf{8.99 \text{ kg air / kg steam}}\end{aligned}$$

(b) Noting that $\dot{Q} \cong \dot{W} \cong \Delta ke \cong \Delta pe \cong 0$ for the open FWH, the steady-flow energy balance equation yields

$$\begin{aligned}\dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \stackrel{\phi^0(\text{steady})}{=} 0 \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \longrightarrow \dot{m}_2 h_2 + \dot{m}_6 h_6 = \dot{m}_3 h_3 \longrightarrow y h_6 + (1 - y) h_2 = (1) h_3\end{aligned}$$

Thus,

$$\begin{aligned}y &= \frac{h_3 - h_2}{h_6 - h_2} = \frac{670.38 - 252.01}{2586.1 - 252.01} = 0.1792 \quad (\text{the fraction of steam extracted}) \\ w_T &= h_5 - h_6 + (1 - y)(h_6 - h_7) \\ &= 3139.4 - 2586.1 + (1 - 0.1792)(2586.1 - 2095.2) = 956.23 \text{ kJ/kg} \\ w_{\text{net,steam}} &= w_T - w_{p,\text{in}} = w_T - (1 - y)w_{p,I} - w_{p,II} \\ &= 956.23 - (1 - 0.1792)(0.59) - 8.15 = 948.56 \text{ kJ/kg} \\ w_{\text{net,gas}} &= w_T - w_{C,\text{in}} = (h_{10} - h_{11}) - (h_9 - h_8) \\ &= 1515.42 - 735.8 - (635.5 - 300.19) = 444.3 \text{ kJ/kg}\end{aligned}$$

The net work output per unit mass of gas is

$$\begin{aligned}w_{\text{net}} &= w_{\text{net,gas}} + \frac{1}{8.99} w_{\text{net,steam}} = 444.3 + \frac{1}{8.99}(948.56) = 549.8 \text{ kJ/kg} \\ \dot{m}_{\text{air}} &= \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{450,000 \text{ kJ/s}}{549.7 \text{ kJ/kg}} = 818.7 \text{ kg/s}\end{aligned}$$

and

$$\dot{Q}_{\text{in}} = \dot{m}_{\text{air}} (h_{10} - h_9) = (818.5 \text{ kg/s})(1515.42 - 635.5) \text{ kJ/kg} = \mathbf{720,215 \text{ kW}}$$

$$(c) \quad \eta_{th} = \frac{\dot{W}_{\text{net}}}{\dot{Q}_{\text{in}}} = \frac{450,000 \text{ kW}}{720,215 \text{ kW}} = \mathbf{62.5\%}$$

10-79 Problem 10-78 is reconsidered. The effect of the gas cycle pressure ratio on the ratio of gas flow rate to steam flow rate and cycle thermal efficiency is to be investigated.

Analysis The problem is solved using EES, and the solution is given below.

10-80 A 450-MW combined gas-steam power plant is considered. The topping cycle is a gas-turbine cycle and the bottoming cycle is a nonideal Rankine cycle with an open feedwater heater. The mass flow rate of air to steam, the required rate of heat input in the combustion chamber, and the thermal efficiency of the combined cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with variable specific heats.

Analysis (a) Using the properties of air from Table A-17, the analysis of gas cycle yields

$$T_8 = 300 \text{ K} \longrightarrow h_8 = 300.19 \text{ kJ/kg}$$

$$P_{r_8} = 1.386$$

$$P_{r_9} = \frac{P_9}{P_8} P_{r_8} = (14)(1.386) = 19.40 \longrightarrow h_{9s} = 635.5 \text{ kJ/kg}$$

$$\eta_C = \frac{h_{9s} - h_8}{h_9 - h_8} \longrightarrow h_9 = h_8 + (h_{9s} - h_8)/\eta_C$$

$$= 300.19 + (635.5 - 300.19)/(0.82)$$

$$= 709.1 \text{ kJ/kg}$$

$$T_{10} = 1400 \text{ K} \longrightarrow h_{10} = 1515.42 \text{ kJ/kg}$$

$$P_{r_{10}} = 450.5$$

$$P_{r_{11}} = \frac{P_{11}}{P_{10}} P_{r_{10}} = \left(\frac{1}{14}\right)(450.5) = 32.18 \longrightarrow h_{11s} = 735.8 \text{ kJ/kg}$$

$$\eta_T = \frac{h_{10} - h_{11}}{h_{10} - h_{11s}} \longrightarrow h_{11} = h_{10} - \eta_T(h_{10} - h_{11s})$$

$$= 1515.42 - (0.86)(1515.42 - 735.8)$$

$$= 844.95 \text{ kJ/kg}$$

$$T_{12} = 460 \text{ K} \longrightarrow h_{12} = 462.02 \text{ kJ/kg}$$

From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 20 \text{ kPa} = 251.42 \text{ kJ/kg}$$

$$\nu_1 = \nu_f @ 20 \text{ kPa} = 0.001017 \text{ m}^3/\text{kg}$$

$$w_{pI, \text{in}} = \nu_1(P_2 - P_1)$$

$$= (0.001017 \text{ m}^3/\text{kg})(600 - 20 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3}\right)$$

$$= 0.59 \text{ kJ/kg}$$

$$h_2 = h_1 + w_{pI, \text{in}} = 251.42 + 0.59 = 252.01 \text{ kJ/kg}$$

$$h_3 = h_f @ 0.6 \text{ MPa} = 670.38 \text{ kJ/kg}$$

$$\nu_3 = \nu_f @ 0.6 \text{ MPa} = 0.001101 \text{ m}^3/\text{kg}$$

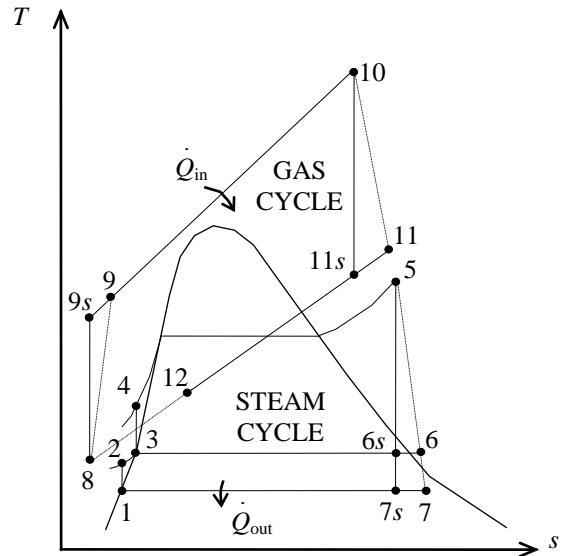

$$w_{pII, \text{in}} = \nu_3(P_4 - P_3)$$

$$= (0.001101 \text{ m}^3/\text{kg})(8,000 - 600 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3}\right)$$

$$= 8.15 \text{ kJ/kg}$$

$$h_4 = h_3 + w_{pII, \text{in}} = 670.38 + 8.15 = 678.52 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_5 = 8 \text{ MPa} \\ T_5 = 400^\circ\text{C} \end{array} \right\} \begin{array}{l} h_5 = 3139.4 \text{ kJ/kg} \\ s_5 = 6.3658 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$P_6 = 0.6 \text{ MPa} \left\{ \begin{array}{l} x_{6s} = \frac{s_{6s} - s_f}{s_{fg}} = \frac{6.3658 - 1.9308}{4.8285} = 0.9184 \\ h_{6s} = h_f + x_{6s} h_{fg} = 670.38 + (0.9184)(2085.8) = 2585.9 \text{ kJ/kg} \end{array} \right.$$

$$\eta_T = \frac{h_5 - h_6}{h_5 - h_{6s}} \longrightarrow h_6 = h_5 - \eta_T (h_5 - h_{6s}) = 3139.4 - (0.86)(3139.4 - 2585.9) = 2663.3 \text{ kJ/kg}$$

$$P_7 = 20 \text{ kPa} \left\{ \begin{array}{l} x_{7s} = \frac{s_7 - s_f}{s_{fg}} = \frac{6.3658 - 0.8320}{7.0752} = 0.7820 \\ h_{7s} = h_f + x_7 h_{fg} = 251.42 + (0.7820)(2357.5) = 2095.1 \text{ kJ/kg} \end{array} \right.$$

$$\eta_T = \frac{h_5 - h_7}{h_5 - h_{7s}} \longrightarrow h_7 = h_5 - \eta_T (h_5 - h_{7s}) = 3139.4 - (0.86)(3139.4 - 2095.1) = 2241.3 \text{ kJ/kg}$$

Noting that $\dot{Q} \cong \dot{W} \cong \Delta ke \cong \Delta pe \cong 0$ for the heat exchanger, the steady-flow energy balance equation yields

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \overset{\phi^0(\text{steady})}{=} 0 \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \longrightarrow \dot{m}_s (h_5 - h_4) = \dot{m}_{\text{air}} (h_{11} - h_{12}) \\ \frac{\dot{m}_{\text{air}}}{\dot{m}_s} &= \frac{h_5 - h_4}{h_{11} - h_{12}} = \frac{3139.4 - 678.52}{844.95 - 462.02} = \mathbf{6.425 \text{ kg air / kg steam}} \end{aligned}$$

(b) Noting that $\dot{Q} \cong \dot{W} \cong \Delta ke \cong \Delta pe \cong 0$ for the open FWH, the steady-flow energy balance equation yields

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \overset{\phi^0(\text{steady})}{=} 0 \rightarrow \dot{E}_{\text{in}} = \dot{E}_{\text{out}} \\ \sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \longrightarrow \dot{m}_2 h_2 + \dot{m}_6 h_6 = \dot{m}_3 h_3 \longrightarrow y h_6 + (1 - y) h_2 = (1) h_3 \end{aligned}$$

Thus,

$$\begin{aligned} y &= \frac{h_3 - h_2}{h_6 - h_2} = \frac{670.38 - 252.01}{2663.3 - 252.01} = 0.1735 \text{ (the fraction of steam extracted)} \\ w_T &= \eta_T [h_5 - h_6 + (1 - y)(h_6 - h_7)] \\ &= (0.86)[3139.4 - 2663.3 + (1 - 0.1735)(2663.3 - 2241.3)] = 824.5 \text{ kJ/kg} \\ w_{\text{net,steam}} &= w_T - w_{p,\text{in}} = w_T - (1 - y)w_{p,I} - w_{p,II} \\ &= 824.5 - (1 - 0.1735)(0.59) - 8.15 = 815.9 \text{ kJ/kg} \\ w_{\text{net,gas}} &= w_T - w_{C,\text{in}} = (h_{10} - h_{11}) - (h_9 - h_8) \\ &= 1515.42 - 844.95 - (709.1 - 300.19) = 261.56 \text{ kJ/kg} \end{aligned}$$

The net work output per unit mass of gas is

$$\begin{aligned} w_{\text{net}} &= w_{\text{net,gas}} + \frac{1}{6.423} w_{\text{net,steam}} = 261.56 + \frac{1}{6.425}(815.9) = 388.55 \text{ kJ/kg} \\ \dot{m}_{\text{air}} &= \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{450,000 \text{ kJ/s}}{388.55 \text{ kJ/kg}} = 1158.2 \text{ kg/s} \end{aligned}$$

and $\dot{Q}_{\text{in}} = \dot{m}_{\text{air}} (h_{10} - h_9) = (1158.2 \text{ kg/s})(1515.42 - 709.1) \text{ kJ/kg} = \mathbf{933,850 \text{ kW}}$

$$(c) \quad \eta_{th} = \frac{\dot{W}_{\text{net}}}{\dot{Q}_{\text{in}}} = \frac{450,000 \text{ kW}}{933,850 \text{ kW}} = \mathbf{48.2\%}$$

10-81 Problem 10-80 is reconsidered. The effect of the gas cycle pressure ratio on the ratio of gas flow rate to steam flow rate and cycle thermal efficiency is to be investigated.

Analysis The problem is solved using EES, and the solution is given below.

Cycle Thermal Efficiency vs Gas Cycle Pressure Ratio

$W_{\dot{g},gas} / W_{\dot{g},steam}$ vs Gas Pressure Ratio

Ratio of Gas Flow Rate to Steam Flow Rate vs Gas Pressure Ratio

10-82 A 280-MW combined gas-steam power plant is considered. The topping cycle is a gas-turbine cycle and the bottoming cycle is a nonideal Rankine cycle with an open feedwater heater. The mass flow rate of air to steam, the required rate of heat input in the combustion chamber, and the thermal efficiency of the combined cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with variable specific heats.

Analysis (a) Using the properties of air from Table A-17, the analysis of gas cycle yields

$$T_8 = 300 \text{ K} \longrightarrow h_8 = 300.19 \text{ kJ/kg} \\ P_{r_8} = 1.386$$

$$P_{r_9} = \frac{P_9}{P_8} P_{r_8} = (11)(1.386) = 15.25 \longrightarrow h_{9s} = 595.84 \text{ kJ/kg}$$

$$\eta_C = \frac{h_{9s} - h_8}{h_9 - h_8} \longrightarrow h_9 = h_8 + (h_{9s} - h_8) / \eta_C \\ = 300.19 + (595.84 - 300.19) / (0.82) \\ = 660.74 \text{ kJ/kg}$$

$$T_{10} = 1100 \text{ K} \longrightarrow h_{10} = 1161.07 \text{ kJ/kg} \\ P_{r_{10}} = 167.1$$

$$P_{r_{11}} = \frac{P_{11}}{P_{10}} P_{r_{10}} = \left(\frac{1}{11}\right)(167.1) = 15.19 \longrightarrow h_{11s} = 595.18 \text{ kJ/kg}$$

$$\eta_T = \frac{h_{10} - h_{11}}{h_{10} - h_{11s}} \longrightarrow h_{11} = h_{10} - \eta_T (h_{10} - h_{11s}) \\ = 1161.07 - (0.86)(1161.07 - 595.18) \\ = 674.40 \text{ kJ/kg}$$

$$T_{12} = 420 \text{ K} \longrightarrow h_{12} = 421.26 \text{ kJ/kg}$$

From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 10 \text{ kPa} = 191.81 \text{ kJ/kg}$$

$$\nu_1 = \nu_f @ 10 \text{ kPa} = 0.00101 \text{ m}^3/\text{kg}$$

$$w_{pI, \text{in}} = \nu_1 (P_2 - P_1) \\ = (0.00101 \text{ m}^3/\text{kg})(800 - 10 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ = 0.80 \text{ kJ/kg}$$

$$h_2 = h_1 + w_{pI, \text{in}} = 191.81 + 0.80 = 192.60 \text{ kJ/kg}$$

$$h_3 = h_f @ 0.8 \text{ MPa} = 720.87 \text{ kJ/kg}$$

$$\nu_3 = \nu_f @ 0.8 \text{ MPa} = 0.001115 \text{ m}^3/\text{kg}$$

$$w_{pII, \text{in}} = \nu_3 (P_4 - P_3) \\ = (0.001115 \text{ m}^3/\text{kg})(5000 - 800 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ = 4.68 \text{ kJ/kg}$$

$$h_4 = h_3 + w_{pII, \text{in}} = 720.87 + 4.68 = 725.55 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_5 = 5 \text{ MPa} \\ T_5 = 350^\circ\text{C} \end{array} \right\} \begin{array}{l} h_5 = 3069.3 \text{ kJ/kg} \\ s_5 = 6.4516 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$P_6 = 0.8 \text{ MPa} \left\{ \begin{array}{l} x_{6s} = \frac{s_{6s} - s_f}{s_{fg}} = \frac{6.4516 - 2.0457}{4.6160} = 0.9545 \\ h_{6s} = h_f + x_{6s} h_{fg} = 720.87 + (0.9545)(2085.8) = 2675.1 \text{ kJ/kg} \end{array} \right.$$

$$\eta_T = \frac{h_5 - h_6}{h_5 - h_{6s}} \longrightarrow h_6 = h_5 - \eta_T (h_5 - h_{6s}) = 3069.3 - (0.86)(3069.3 - 2675.1) = 2730.3 \text{ kJ/kg}$$

$$P_7 = 10 \text{ kPa} \left\{ \begin{array}{l} x_{7s} = \frac{s_7 - s_f}{s_{fg}} = \frac{6.4516 - 0.6492}{7.4996} = 0.7737 \\ h_{7s} = h_f + x_7 h_{fg} = 191.81 + (0.7737)(2392.1) = 2042.5 \text{ kJ/kg} \end{array} \right.$$

$$\eta_T = \frac{h_5 - h_7}{h_5 - h_{7s}} \longrightarrow h_7 = h_5 - \eta_T (h_5 - h_{7s}) = 3069.3 - (0.86)(3069.3 - 2042.5) = 2186.3 \text{ kJ/kg}$$

Noting that $\dot{Q} \cong \dot{W} \cong \Delta ke \cong \Delta pe \cong 0$ for the heat exchanger, the steady-flow energy balance equation yields

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \stackrel{\text{0(steady)}}{=} 0 \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \longrightarrow \dot{m}_s (h_5 - h_4) = \dot{m}_{\text{air}} (h_{11} - h_{12}) \\ \frac{\dot{m}_{\text{air}}}{\dot{m}_s} &= \frac{h_5 - h_4}{h_{11} - h_{12}} = \frac{3069.3 - 725.55}{674.40 - 421.26} = \mathbf{9.259 \text{ kg air / kg steam}} \end{aligned}$$

(b) Noting that $\dot{Q} \cong \dot{W} \cong \Delta ke \cong \Delta pe \cong 0$ for the open FWH, the steady-flow energy balance equation yields

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \stackrel{\text{0(steady)}}{=} 0 \rightarrow \dot{E}_{\text{in}} = \dot{E}_{\text{out}} \\ \sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \longrightarrow \dot{m}_2 h_2 + \dot{m}_6 h_6 = \dot{m}_3 h_3 \longrightarrow y h_6 + (1 - y) h_2 = (1) h_3 \end{aligned}$$

Thus,

$$\begin{aligned} y &= \frac{h_3 - h_2}{h_6 - h_2} = \frac{720.87 - 192.60}{2730.3 - 192.60} = 0.2082 \text{ (the fraction of steam extracted)} \\ w_T &= \eta_T [h_5 - h_6 + (1 - y)(h_6 - h_7)] \\ &= (0.86)[3069.3 - 2730.3 + (1 - 0.2082)(2730.3 - 2186.3)] = 769.8 \text{ kJ/kg} \\ w_{\text{net,steam}} &= w_T - w_{p,\text{in}} = w_T - (1 - y)w_{p,\text{I}} - w_{p,\text{II}} \\ &= 769.8 - (1 - 0.2082)(0.80) - 4.68 = 764.5 \text{ kJ/kg} \\ w_{\text{net,gas}} &= w_T - w_{C,\text{in}} = (h_{10} - h_{11}) - (h_9 - h_8) \\ &= 1161.07 - 674.40 - (660.74 - 300.19) = 126.12 \text{ kJ/kg} \end{aligned}$$

The net work output per unit mass of gas is

$$w_{\text{net}} = w_{\text{net,gas}} + \frac{1}{6.425} w_{\text{net,steam}} = 126.12 + \frac{1}{9.259} (764.5) = 208.69 \text{ kJ/kg}$$

$$\dot{m}_{\text{air}} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{280,000 \text{ kJ/s}}{208.69 \text{ kJ/kg}} = 1341.7 \text{ kg/s}$$

and $\dot{Q}_{\text{in}} = \dot{m}_{\text{air}} (h_{10} - h_9) = (1341.7 \text{ kg/s})(1161.07 - 660.74) \text{ kJ/kg} = \mathbf{671,300 \text{ kW}}$

(c) $\eta_{\text{th}} = \frac{\dot{W}_{\text{net}}}{\dot{Q}_{\text{in}}} = \frac{280,000 \text{ kW}}{671,300 \text{ kW}} = 0.4171 = \mathbf{41.7\%}$

10-83 Problem 10-82 is reconsidered. The effect of the gas cycle pressure ratio on the ratio of gas flow rate to steam flow rate and cycle thermal efficiency is to be investigated.

Analysis The problem is solved using EES, and the solution is given below.

10-84 A combined gas-steam power plant is considered. The topping cycle is a gas-turbine cycle and the bottoming cycle is a nonideal reheat Rankine cycle. The moisture percentage at the exit of the low-pressure turbine, the steam temperature at the inlet of the high-pressure turbine, and the thermal efficiency of the combined cycle are to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with variable specific heats.

Analysis (a) We obtain the air properties from EES. The analysis of gas cycle is as follows

$$T_7 = 15^\circ\text{C} \longrightarrow h_7 = 288.53 \text{ kJ/kg}$$

$$\left. \begin{array}{l} T_7 = 15^\circ\text{C} \\ P_7 = 100 \text{ kPa} \end{array} \right\} s_7 = 5.6649 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_8 = 700 \text{ kPa} \\ s_8 = s_7 \end{array} \right\} h_{8s} = 503.70 \text{ kJ/kg}$$

$$\eta_C = \frac{h_{8s} - h_7}{h_8 - h_7} \longrightarrow h_8 = h_7 + (h_{8s} - h_7)/\eta_C \\ = 288.53 + (503.70 - 288.53)/(0.80) \\ = 557.49 \text{ kJ/kg}$$

$$T_9 = 950^\circ\text{C} \longrightarrow h_9 = 1305.2 \text{ kJ/kg}$$

$$\left. \begin{array}{l} T_9 = 950^\circ\text{C} \\ P_9 = 700 \text{ kPa} \end{array} \right\} s_9 = 6.6456 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_{10} = 100 \text{ kPa} \\ s_{10} = s_9 \end{array} \right\} h_{10s} = 764.01 \text{ kJ/kg}$$

$$\eta_T = \frac{h_9 - h_{10}}{h_9 - h_{10s}} \longrightarrow h_{10} = h_9 - \eta_T(h_9 - h_{10s}) \\ = 1305.2 - (0.80)(1305.2 - 764.01) \\ = 872.25 \text{ kJ/kg}$$

$$T_{11} = 200^\circ\text{C} \longrightarrow h_{11} = 475.77 \text{ kJ/kg}$$

From the steam tables (Tables A-4, A-5, and A-6 or from EES),

$$h_1 = h_f @ 10 \text{ kPa} = 191.81 \text{ kJ/kg}$$

$$v_1 = v_f @ 10 \text{ kPa} = 0.00101 \text{ m}^3/\text{kg}$$

$$w_{p,\text{lin}} = v_1(P_2 - P_1)/\eta_p \\ = (0.00101 \text{ m}^3/\text{kg})(6000 - 10 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) / 0.80 \\ = 7.56 \text{ kJ/kg}$$

$$h_2 = h_1 + w_{p,\text{lin}} = 191.81 + 7.65 = 199.37 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_5 = 1 \text{ MPa} \\ T_5 = 400^\circ\text{C} \end{array} \right\} \begin{array}{l} h_5 = 3264.5 \text{ kJ/kg} \\ s_5 = 7.4670 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_6 = 10 \text{ kPa} \\ s_{6s} = s_5 \end{array} \right\} \begin{array}{l} x_{6s} = \frac{s_{6s} - s_f}{s_{fg}} = \frac{7.4670 - 0.6492}{7.4996} = 0.9091 \\ h_{6s} = h_f + x_{6s}h_{fg} = 191.81 + (0.9091)(2392.1) = 2366.4 \text{ kJ/kg} \end{array}$$

$$\eta_T = \frac{h_5 - h_6}{h_5 - h_{6s}} \longrightarrow h_6 = h_5 - \eta_T (h_5 - h_{6s})$$

$$= 3264.5 - (0.80)(3264.5 - 2366.4)$$

$$= 2546.0 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_6 = 10 \text{ kPa} \\ h_6 = 2546.5 \text{ kJ/kg} \end{array} \right\} x_6 = 0.9842$$

$$\text{Moisture Percentage} = 1 - x_6 = 1 - 0.9842 = 0.0158 = \mathbf{1.58\%}$$

(b) Noting that $\dot{Q} \cong \dot{W} \cong \Delta ke \cong \Delta pe \cong 0$ for the heat exchanger, the steady-flow energy balance equation yields

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e$$

$$\dot{m}_s (h_3 - h_2) + \dot{m}_s (h_5 - h_4) = \dot{m}_{\text{air}} (h_{10} - h_{11})$$

$$(4.6)[(3350.3 - 199.37) + (3264.5 - h_4)] = (40)(872.25 - 475.77) \longrightarrow h_4 = 2967.8 \text{ kJ/kg}$$

Also,

$$\left. \begin{array}{l} P_3 = 6 \text{ MPa} \\ T_3 = ? \end{array} \right\} h_3 =$$

$$\left. \begin{array}{l} P_4 = 1 \text{ MPa} \\ s_{4s} = s_3 \end{array} \right\} h_{4s} =$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow h_4 = h_3 - \eta_T (h_3 - h_{4s})$$

The temperature at the inlet of the high-pressure turbine may be obtained by a trial-error approach or using EES from the above relations. The answer is $T_3 = \mathbf{469.6^\circ\text{C}}$. Then, the enthalpy at state 3 becomes: $h_3 = 3350.3 \text{ kJ/kg}$

$$(c) \quad \dot{W}_{\text{T,gas}} = \dot{m}_{\text{air}} (h_9 - h_{10}) = (40 \text{ kg/s})(1305.2 - 872.25) \text{ kJ/kg} = 17,318 \text{ kW}$$

$$\dot{W}_{\text{C,gas}} = \dot{m}_{\text{air}} (h_8 - h_7) = (40 \text{ kg/s})(557.49 - 288.53) \text{ kJ/kg} = 10,758 \text{ kW}$$

$$\dot{W}_{\text{net,gas}} = \dot{W}_{\text{T,gas}} - \dot{W}_{\text{C,gas}} = 17,318 - 10,758 = 6560 \text{ kW}$$

$$\dot{W}_{\text{T,steam}} = \dot{m}_s (h_3 - h_4 + h_5 - h_6) = (4.6 \text{ kg/s})(3350.3 - 2967.8 + 3264.5 - 2546.0) \text{ kJ/kg} = 5065 \text{ kW}$$

$$\dot{W}_{\text{P,steam}} = \dot{m}_s w_{\text{pump}} = (4.6 \text{ kg/s})(7.564) \text{ kJ/kg} = 34.8 \text{ kW}$$

$$\dot{W}_{\text{net,steam}} = \dot{W}_{\text{T,steam}} - \dot{W}_{\text{P,steam}} = 5065 - 34.8 = 5030 \text{ kW}$$

$$\dot{W}_{\text{net,plant}} = \dot{W}_{\text{net,gas}} + \dot{W}_{\text{net,steam}} = 6560 + 5030 = \mathbf{11,590 \text{ kW}}$$

$$(d) \quad \dot{Q}_{\text{in}} = \dot{m}_{\text{air}} (h_9 - h_8) = (40 \text{ kg/s})(1305.2 - 557.49) \text{ kJ/kg} = 29,908 \text{ kW}$$

$$\eta_{\text{th}} = \frac{\dot{W}_{\text{net,plant}}}{\dot{Q}_{\text{in}}} = \frac{11,590 \text{ kW}}{29,908 \text{ kW}} = 0.3875 = \mathbf{38.8\%}$$

Special Topic: Binary Vapor Cycles

10-85C Steam is not an ideal fluid for vapor power cycles because its critical temperature is low, its saturation dome resembles an inverted V, and its condenser pressure is too low.

10-86C Binary power cycle is a cycle which is actually a combination of two cycles; one in the high temperature region, and the other in the low temperature region. Its purpose is to increase thermal efficiency.

10-87C In binary vapor power cycles, both cycles are vapor cycles. In the combined gas-steam power cycle, one of the cycles is a gas cycle.

10-88C Because mercury has a high critical temperature, relatively low critical pressure, but a very low condenser pressure. It is also toxic, expensive, and has a low enthalpy of vaporization.

10-89 Consider the heat exchanger of a binary power cycle. The working fluid of the topping cycle (cycle A) enters the heat exchanger at state 1 and leaves at state 2. The working fluid of the bottoming cycle (cycle B) enters at state 3 and leaves at state 4. Neglecting any changes in kinetic and potential energies, and assuming the heat exchanger is well-insulated, the steady-flow energy balance relation yields

$$\begin{aligned}\dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \stackrel{\text{0 (steady)}}{=} 0 \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \sum \dot{m}_e h_e &= \sum \dot{m}_i h_i \\ \dot{m}_A h_2 + \dot{m}_B h_4 &= \dot{m}_A h_1 + \dot{m}_B h_3 \text{ or } \dot{m}_A (h_2 - h_1) = \dot{m}_B (h_3 - h_4)\end{aligned}$$

Thus,

$$\frac{\dot{m}_A}{\dot{m}_B} = \frac{h_3 - h_4}{h_2 - h_1}$$

Review Problems

10-90 A steam power plant operates on the simple ideal Rankine cycle. The turbine inlet temperature, the net power output, the thermal efficiency, and the minimum mass flow rate of the cooling water required are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 7.5 \text{ kPa} = 168.75 \text{ kJ/kg}$$

$$v_1 = v_f @ 7.5 \text{ kPa} = 0.001008 \text{ m}^3/\text{kg}$$

$$T_1 = T_{\text{sat}} @ 7.5 \text{ kPa} = 40.29^\circ\text{C}$$

$$\begin{aligned} w_{p,\text{in}} &= v_1(P_2 - P_1) \\ &= (0.001008 \text{ m}^3/\text{kg})(6000 - 7.5 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 6.04 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 168.75 + 6.04 = 174.79 \text{ kJ/kg}$$

$$h_4 = h_g @ 7.5 \text{ kPa} = 2574.0 \text{ kJ/kg}$$

$$s_4 = s_g @ 7.5 \text{ kPa} = 8.2501 \text{ kJ/kg}$$

$$\left. \begin{aligned} P_3 &= 6 \text{ MPa} \\ s_3 &= s_4 \end{aligned} \right\} \begin{aligned} h_3 &= 4852.2 \text{ kJ/kg} \\ T_3 &= 1089.2^\circ\text{C} \end{aligned}$$

$$(b) \quad q_{\text{in}} = h_3 - h_2 = 4852.2 - 174.79 = 4677.4 \text{ kJ/kg}$$

$$q_{\text{out}} = h_4 - h_1 = 2574.0 - 168.75 = 2405.3 \text{ kJ/kg}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 4677.4 - 2405.3 = 2272.1 \text{ kJ/kg}$$

and

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{2272.1 \text{ kJ/kg}}{4677.4 \text{ kJ/kg}} = \mathbf{48.6\%}$$

Thus,

$$\dot{W}_{\text{net}} = \eta_{\text{th}} \dot{Q}_{\text{in}} = (0.4857)(40,000 \text{ kJ/s}) = \mathbf{19,428 \text{ kJ/s}}$$

(c) The mass flow rate of the cooling water will be minimum when it is heated to the temperature of the steam in the condenser, which is 40.29°C ,

$$\dot{Q}_{\text{out}} = \dot{Q}_{\text{in}} - \dot{W}_{\text{net}} = 40,000 - 19,428 = 20,572 \text{ kJ/s}$$

$$\dot{m}_{\text{cool}} = \frac{\dot{Q}_{\text{out}}}{c\Delta T} = \frac{20,572 \text{ kJ/s}}{(4.18 \text{ kJ/kg} \cdot ^\circ\text{C})(40.29 - 15^\circ\text{C})} = \mathbf{194.6 \text{ kg/s}}$$

10-91 A simple ideal Rankine cycle with water as the working fluid operates between the specified pressure limits. The thermal efficiency of the cycle is to be compared when it is operated so that the liquid enters the pump as a saturated liquid against that when the liquid enters as a subcooled liquid.

determined power produced by the turbine and consumed by the pump are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the steam tables (Tables A-4, A-5, and A-6),

$$\begin{aligned}
 h_1 &= h_f @ 50 \text{ kPa} = 340.54 \text{ kJ/kg} \\
 v_1 &= v_f @ 20 \text{ kPa} = 0.001030 \text{ m}^3/\text{kg} \\
 w_{p,\text{in}} &= v_1 (P_2 - P_1) \\
 &= (0.001030 \text{ m}^3/\text{kg})(6000 - 50) \text{ kPa} \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\
 &= 6.13 \text{ kJ/kg} \\
 h_2 &= h_1 + w_{p,\text{in}} = 340.54 + 6.13 = 346.67 \text{ kJ/kg} \\
 \left. \begin{array}{l} P_3 = 6000 \text{ kPa} \\ T_3 = 600^\circ\text{C} \end{array} \right\} & \begin{array}{l} h_3 = 3658.8 \text{ kJ/kg} \\ s_3 = 7.1693 \text{ kJ/kg} \cdot \text{K} \end{array} \\
 \left. \begin{array}{l} P_4 = 50 \text{ kPa} \\ s_4 = s_3 \end{array} \right\} & \begin{array}{l} x_4 = \frac{s_4 - s_f}{s_{fg}} = \frac{7.1693 - 1.0912}{6.5019} = 0.9348 \\ h_4 = h_f + x_4 h_{fg} = 340.54 + (0.9348)(2304.7) = 2495.0 \text{ kJ/kg} \end{array}
 \end{aligned}$$

Thus,

$$\begin{aligned}
 q_{\text{in}} &= h_3 - h_2 = 3658.8 - 346.67 = 3312.1 \text{ kJ/kg} \\
 q_{\text{out}} &= h_4 - h_1 = 2495.0 - 340.54 = 2154.5 \text{ kJ/kg}
 \end{aligned}$$

and the thermal efficiency of the cycle is

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{2154.5}{3312.1} = \mathbf{0.3495}$$

When the liquid enters the pump 11.3°C cooler than a saturated liquid at the condenser pressure, the enthalpies become

$$\left. \begin{array}{l} P_1 = 50 \text{ kPa} \\ T_1 = T_{\text{sat}} @ 50 \text{ kPa} - 11.3 = 81.3 - 11.3 = 70^\circ\text{C} \end{array} \right\} \begin{array}{l} h_1 \cong h_f @ 70^\circ\text{C} = 293.07 \text{ kJ/kg} \\ v_1 \cong v_f @ 70^\circ\text{C} = 0.001023 \text{ m}^3/\text{kg} \end{array}$$

$$\begin{aligned}
 w_{p,\text{in}} &= v_1 (P_2 - P_1) \\
 &= (0.001023 \text{ m}^3/\text{kg})(6000 - 50) \text{ kPa} \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\
 &= 6.09 \text{ kJ/kg}
 \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 293.07 + 6.09 = 299.16 \text{ kJ/kg}$$

Then,

$$\begin{aligned}
 q_{\text{in}} &= h_3 - h_2 = 3658.8 - 299.16 = 3359.6 \text{ kJ/kg} \\
 q_{\text{out}} &= h_4 - h_1 = 2495.0 - 293.09 = 2201.9 \text{ kJ/kg}
 \end{aligned}$$

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{2201.9}{3359.6} = \mathbf{0.3446}$$

The thermal efficiency slightly decreases as a result of subcooling at the pump inlet.

10-92 A steam power plant operating on an ideal Rankine cycle with two stages of reheat is considered. The thermal efficiency of the cycle and the mass flow rate of the steam are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) From the steam tables (Tables A-4, A-5, and A-6),

$$\begin{aligned} h_1 &= h_f @ 30 \text{ kPa} = 289.18 \text{ kJ/kg} \\ \nu_1 &= \nu_f @ 30 \text{ kPa} = 0.001022 \text{ m}^3/\text{kg} \\ w_{p,\text{in}} &= \nu_1 (P_2 - P_1) \\ &= (0.001022 \text{ m}^3/\text{kg})(10,000 - 30 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 10.19 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 289.18 + 10.19 = 299.37 \text{ kJ/kg}$$

$$\left. \begin{aligned} P_3 &= 10 \text{ MPa} \\ T_3 &= 550^\circ\text{C} \end{aligned} \right\} \begin{aligned} h_3 &= 3500.9 \text{ kJ/kg} \\ s_3 &= 6.7561 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

$$\left. \begin{aligned} P_4 &= 4 \text{ MPa} \\ s_4 &= s_3 \end{aligned} \right\} h_4 = 3204.9 \text{ kJ/kg}$$

$$\left. \begin{aligned} P_5 &= 4 \text{ MPa} \\ T_5 &= 550^\circ\text{C} \end{aligned} \right\} \begin{aligned} h_5 &= 3559.7 \text{ kJ/kg} \\ s_5 &= 7.2335 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

$$\left. \begin{aligned} P_6 &= 2 \text{ MPa} \\ s_6 &= s_5 \end{aligned} \right\} h_6 = 3321.1 \text{ kJ/kg}$$

$$\left. \begin{aligned} P_7 &= 2 \text{ MPa} \\ T_7 &= 550^\circ\text{C} \end{aligned} \right\} \begin{aligned} h_7 &= 3578.4 \text{ kJ/kg} \\ s_7 &= 7.5706 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

$$\left. \begin{aligned} P_8 &= 30 \text{ kPa} \\ s_8 &= s_7 \end{aligned} \right\} \begin{aligned} x_8 &= \frac{s_8 - s_f}{s_{fg}} = \frac{7.5706 - 0.9441}{6.8234} = 0.9711 \\ h_8 &= h_f + x_8 h_{fg} = 289.27 + (0.9711)(2335.3) = 2557.1 \text{ kJ/kg} \end{aligned}$$

Then,

$$\begin{aligned} q_{\text{in}} &= (h_3 - h_2) + (h_5 - h_4) + (h_7 - h_6) \\ &= 3500.9 - 299.37 + 3559.7 - 3204.9 + 3578.4 - 3321.1 = 3813.7 \text{ kJ/kg} \end{aligned}$$

$$q_{\text{out}} = h_8 - h_1 = 2557.1 - 289.18 = 2267.9 \text{ kJ/kg}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 3813.7 - 2267.9 = 1545.8 \text{ kJ/kg}$$

Thus,

$$\eta_{\text{th}} = \frac{w_{\text{net}}}{q_{\text{in}}} = \frac{1545.8 \text{ kJ/kg}}{3813.7 \text{ kJ/kg}} = 0.4053 = \mathbf{40.5\%}$$

(b) The mass flow rate of the steam is then

$$\dot{m} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{75,000 \text{ kJ/s}}{1545.8 \text{ kJ/kg}} = \mathbf{48.5 \text{ kg/s}}$$

10-93 A steam power plant operating on the ideal Rankine cycle with reheating is considered. The reheat pressures of the cycle are to be determined for the cases of single and double reheat.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) Single Reheat: From the steam tables (Tables A-4, A-5, and A-6 or EES),

$$\left. \begin{array}{l} P_6 = 10 \text{ kPa} \\ x_6 = 0.95 \end{array} \right\} \begin{array}{l} h_6 = h_f + x_6 h_{fg} = 191.81 + (0.95)(2392.1) = 2464.3 \text{ kJ/kg} \\ s_6 = s_f + x_6 s_{fg} = 0.6492 + (0.95)(7.4996) = 7.7739 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} T_5 = 700^\circ\text{C} \\ s_5 = s_6 \end{array} \right\} P_5 = \mathbf{2908 \text{ kPa}}$$

(b) Double Reheat:

$$\left. \begin{array}{l} P_3 = 30 \text{ MPa} \\ T_3 = 700^\circ\text{C} \end{array} \right\} s_3 = 6.5599 \text{ kJ/kg} \cdot \text{K}$$

$$\left. \begin{array}{l} P_4 = P_x \\ s_4 = s_3 \end{array} \right\} \text{and} \quad \left. \begin{array}{l} P_5 = P_x \\ T_5 = 700^\circ\text{C} \end{array} \right\}$$

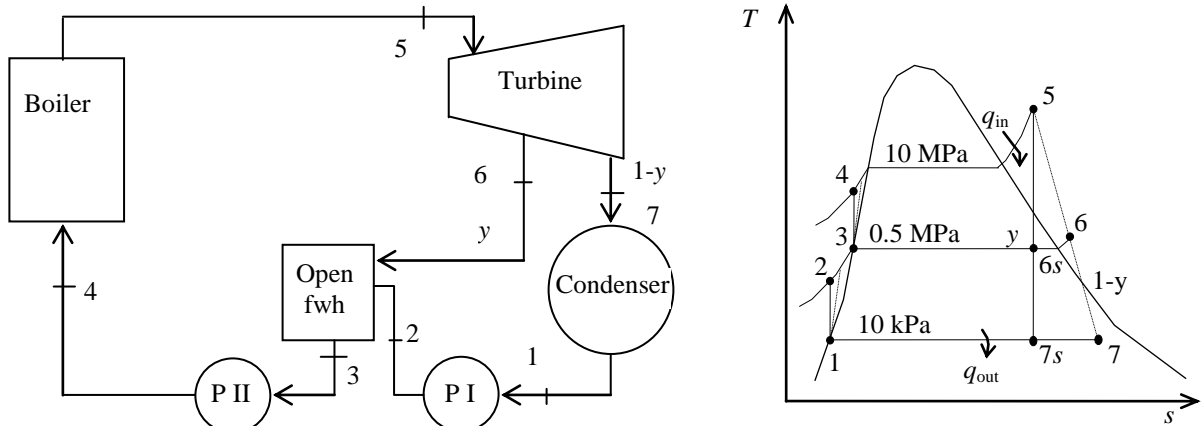

Any pressure P_x selected between the limits of 30 MPa and 2.908 MPa will satisfy the requirements, and can be used for the double reheat pressure.

10-94 An 150-MW steam power plant operating on a regenerative Rankine cycle with an open feedwater heater is considered. The mass flow rate of steam through the boiler, the thermal efficiency of the cycle, and the irreversibility associated with the regeneration process are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis

(a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 10 \text{ kPa} = 191.81 \text{ kJ/kg}$$

$$v_1 = v_f @ 10 \text{ kPa} = 0.00101 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{pI, \text{in}} &= v_1(P_2 - P_1)/\eta_p \\ &= (0.00101 \text{ m}^3/\text{kg})(500 - 10 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) / (0.95) \\ &= 0.52 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{pI, \text{in}} = 191.81 + 0.52 = 192.33 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 0.5 \text{ MPa} \\ \text{sat. liquid} \end{array} \right\} \begin{array}{l} h_3 = h_f @ 0.5 \text{ MPa} = 640.09 \text{ kJ/kg} \\ v_3 = v_f @ 0.5 \text{ MPa} = 0.001093 \text{ m}^3/\text{kg} \end{array}$$

$$\begin{aligned} w_{pII, \text{in}} &= v_3(P_4 - P_3)/\eta_p \\ &= (0.001093 \text{ m}^3/\text{kg})(10,000 - 500 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) / (0.95) \\ &= 10.93 \text{ kJ/kg} \end{aligned}$$

$$h_4 = h_3 + w_{pII, \text{in}} = 640.09 + 10.93 = 651.02 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_5 = 10 \text{ MPa} \\ T_5 = 500^\circ\text{C} \end{array} \right\} \begin{array}{l} h_5 = 3375.1 \text{ kJ/kg} \\ s_5 = 6.5995 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$x_{6s} = \frac{s_{6s} - s_f}{s_{fg}} = \frac{6.5995 - 1.8604}{4.9603} = 0.9554$$

$$\left. \begin{array}{l} P_{6s} = 0.5 \text{ MPa} \\ s_{6s} = s_5 \end{array} \right\} \begin{array}{l} h_{6s} = h_f + x_{6s} h_{fg} = 640.09 + (0.9554)(2108.0) \\ = 2654.1 \text{ kJ/kg} \end{array}$$

$$\begin{aligned} \eta_T = \frac{h_5 - h_6}{h_5 - h_{6s}} &\longrightarrow h_6 = h_5 - \eta_T(h_5 - h_{6s}) \\ &= 3375.1 - (0.80)(3375.1 - 2654.1) \\ &= 2798.3 \text{ kJ/kg} \end{aligned}$$

$$x_{7s} = \frac{s_{7s} - s_f}{s_{fg}} = \frac{6.5995 - 0.6492}{7.4996} = 0.7934$$

$$P_{7s} = 10 \text{ kPa} \left\{ \begin{array}{l} h_{7s} = h_f + x_{7s} h_{fg} = 191.81 + (0.7934)(2392.1) \\ s_{7s} = s_5 \end{array} \right. \left. \begin{array}{l} = 2089.7 \text{ kJ/kg} \end{array} \right.$$

$$\eta_T = \frac{h_5 - h_7}{h_5 - h_{7s}} \longrightarrow h_7 = h_5 - \eta_T (h_5 - h_{7s})$$

$$= 3375.1 - (0.80)(3375.1 - 2089.7)$$

$$= 2346.8 \text{ kJ/kg}$$

The fraction of steam extracted is determined from the steady-flow energy balance equation applied to the feedwater heaters. Noting that $\dot{Q} \cong \dot{W} \cong \Delta ke \cong \Delta pe \cong 0$,

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \overset{\phi 0(\text{steady})}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \longrightarrow \dot{m}_6 h_6 + \dot{m}_2 h_2 = \dot{m}_3 h_3 \longrightarrow y h_6 + (1 - y) h_2 = 1(h_3)$$

where y is the fraction of steam extracted from the turbine ($= \dot{m}_6 / \dot{m}_3$). Solving for y ,

$$y = \frac{h_3 - h_2}{h_6 - h_2} = \frac{640.09 - 192.33}{2798.3 - 192.33} = 0.1718$$

Then,

$$q_{\text{in}} = h_5 - h_4 = 3375.1 - 651.02 = 2724.1 \text{ kJ/kg}$$

$$q_{\text{out}} = (1 - y)(h_7 - h_1) = (1 - 0.1718)(2346.8 - 191.81) = 1784.7 \text{ kJ/kg}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 2724.1 - 1784.7 = 939.4 \text{ kJ/kg}$$

and

$$\dot{m} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{150,000 \text{ kJ/s}}{939.4 \text{ kJ/kg}} = \mathbf{159.7 \text{ kg/s}}$$

(b) The thermal efficiency is determined from

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{1784.7 \text{ kJ/kg}}{2724.1 \text{ kJ/kg}} = \mathbf{34.5\%}$$

Also,

$$\left. \begin{array}{l} P_6 = 0.5 \text{ MPa} \\ h_6 = 2798.3 \text{ kJ/kg} \end{array} \right\} s_6 = 6.9453 \text{ kJ/kg} \cdot \text{K}$$

$$s_3 = s_f @ 0.5 \text{ MPa} = 1.8604 \text{ kJ/kg} \cdot \text{K}$$

$$s_2 = s_1 = s_f @ 10 \text{ kPa} = 0.6492 \text{ kJ/kg} \cdot \text{K}$$

Then the irreversibility (or exergy destruction) associated with this regeneration process is

$$i_{\text{regen}} = T_0 s_{\text{gen}} = T_0 \left(\sum m_e s_e - \sum m_i s_i + \frac{q_{\text{sun}}}{T_L} \overset{\phi 0}{=} \right) = T_0 [s_3 - y s_6 - (1 - y) s_2]$$

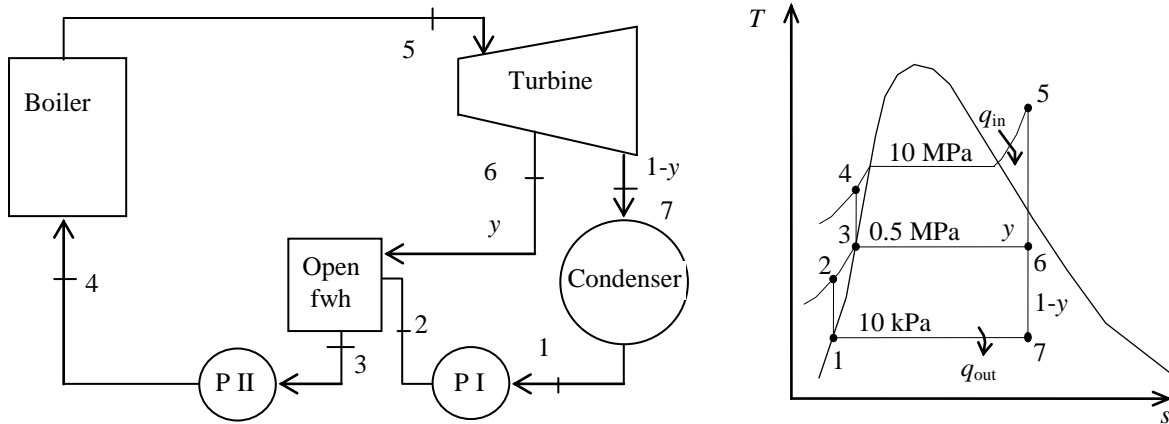

$$= (303 \text{ K}) [1.8604 - (0.1718)(6.9453) - (1 - 0.1718)(0.6492)]$$

$$= \mathbf{39.25 \text{ kJ/kg}}$$

10-95 A 150-MW steam power plant operating on an ideal regenerative Rankine cycle with an open feedwater heater is considered. The mass flow rate of steam through the boiler, the thermal efficiency of the cycle, and the irreversibility associated with the regeneration process are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis

(a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 10 \text{ kPa} = 191.81 \text{ kJ/kg}$$

$$\nu_1 = \nu_f @ 10 \text{ kPa} = 0.00101 \text{ m}^3/\text{kg}$$

$$w_{pI,\text{in}} = \nu_1(P_2 - P_1) = (0.00101 \text{ m}^3/\text{kg})(500 - 10 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) = 0.50 \text{ kJ/kg}$$

$$h_2 = h_1 + w_{pI,\text{in}} = 191.81 + 0.50 = 192.30 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 0.5 \text{ MPa} \\ \text{sat. liquid} \end{array} \right\} \begin{array}{l} h_3 = h_f @ 0.5 \text{ MPa} = 640.09 \text{ kJ/kg} \\ \nu_3 = \nu_f @ 0.5 \text{ MPa} = 0.001093 \text{ m}^3/\text{kg} \end{array}$$

$$w_{pII,\text{in}} = \nu_3(P_4 - P_3) = (0.001093 \text{ m}^3/\text{kg})(10,000 - 500 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) = 10.38 \text{ kJ/kg}$$

$$h_4 = h_3 + w_{pII,\text{in}} = 640.09 + 10.38 = 650.47 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_5 = 10 \text{ MPa} \\ T_5 = 500^\circ\text{C} \end{array} \right\} \begin{array}{l} h_5 = 3375.1 \text{ kJ/kg} \\ s_5 = 6.5995 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_6 = 0.5 \text{ MPa} \\ s_6 = s_5 \end{array} \right\} \begin{array}{l} x_6 = \frac{s_6 - s_f}{s_{fg}} = \frac{6.5995 - 1.8604}{4.9603} = 0.9554 \\ h_6 = h_f + x_6 h_{fg} = 640.09 + (0.9554)(2108.0) = 2654.1 \text{ kJ/kg} \end{array}$$

$$\left. \begin{array}{l} P_7 = 10 \text{ kPa} \\ s_7 = s_5 \end{array} \right\} \begin{array}{l} x_7 = \frac{s_7 - s_f}{s_{fg}} = \frac{6.5995 - 0.6492}{7.4996} = 0.7934 \\ h_7 = h_f + x_7 h_{fg} = 191.81 + (0.7934)(2392.1) = 2089.7 \text{ kJ/kg} \end{array}$$

The fraction of steam extracted is determined from the steady-flow energy equation applied to the feedwater heaters. Noting that $\dot{Q} \cong \dot{W} \cong \Delta ke \cong \Delta pe \cong 0$,

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\phi^0(\text{steady})}{=} 0 \rightarrow \dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \longrightarrow \dot{m}_6 h_6 + \dot{m}_2 h_2 = \dot{m}_3 h_3 \longrightarrow y h_6 + (1 - y) h_2 = 1(h_3)$$

where y is the fraction of steam extracted from the turbine ($= \dot{m}_6 / \dot{m}_3$). Solving for y ,

$$y = \frac{h_3 - h_2}{h_6 - h_2} = \frac{640.09 - 192.31}{2654.1 - 192.31} = 0.1819$$

Then, $q_{\text{in}} = h_5 - h_4 = 3375.1 - 650.47 = 2724.6 \text{ kJ/kg}$
 $q_{\text{out}} = (1 - y)(h_7 - h_1) = (1 - 0.1819)(2089.7 - 191.81) = 1552.7 \text{ kJ/kg}$
 $w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 2724.6 - 1552.7 = 1172.0 \text{ kJ/kg}$

and $\dot{m} = \frac{\dot{W}_{\text{net}}}{w_{\text{net}}} = \frac{150,000 \text{ kJ/s}}{1171.9 \text{ kJ/kg}} = \mathbf{128.0 \text{ kg/s}}$

(b) The thermal efficiency is determined from

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{1552.7 \text{ kJ/kg}}{2724.7 \text{ kJ/kg}} = \mathbf{43.0\%}$$

Also,

$$s_6 = s_5 = 6.5995 \text{ kJ/kg} \cdot \text{K}$$

$$s_3 = s_f @ 0.5 \text{ MPa} = 1.8604 \text{ kJ/kg} \cdot \text{K}$$

$$s_2 = s_1 = s_f @ 10 \text{ kPa} = 0.6492 \text{ kJ/kg} \cdot \text{K}$$

Then the irreversibility (or exergy destruction) associated with this regeneration process is

$$i_{\text{regen}} = T_0 s_{\text{gen}} = T_0 \left(\sum m_e s_e - \sum m_i s_i + \frac{q_{\text{sun}}}{T_L} \right) = T_0 [s_3 - y s_6 - (1 - y) s_2]$$

$$= (303 \text{ K}) [1.8604 - (0.1819)(6.5995) - (1 - 0.1819)(0.6492)]$$

$$= \mathbf{39.0 \text{ kJ/kg}}$$

10-96 An ideal reheat-regenerative Rankine cycle with one open feedwater heater is considered. The fraction of steam extracted for regeneration and the thermal efficiency of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 15 \text{ kPa} = 225.94 \text{ kJ/kg}$$

$$v_1 = v_f @ 15 \text{ kPa} = 0.001014 \text{ m}^3/\text{kg}$$

$$w_{pI, \text{in}} = v_1(P_2 - P_1) = (0.001014 \text{ m}^3/\text{kg})(600 - 15 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) = 0.59 \text{ kJ/kg}$$

$$h_2 = h_1 + w_{pI, \text{in}} = 225.94 + 0.59 = 226.53 \text{ kJ/kg}$$

$$P_3 = 0.6 \text{ MPa} \left. \begin{array}{l} h_3 = h_f @ 0.6 \text{ MPa} = 670.38 \text{ kJ/kg} \\ \text{sat. liquid} \end{array} \right\} v_3 = v_f @ 0.6 \text{ MPa} = 0.001101 \text{ m}^3/\text{kg}$$

$$w_{pII, \text{in}} = v_3(P_4 - P_3) = (0.001101 \text{ m}^3/\text{kg})(10,000 - 600 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) = 10.35 \text{ kJ/kg}$$

$$h_4 = h_3 + w_{pII, \text{in}} = 670.38 + 10.35 = 680.73 \text{ kJ/kg}$$

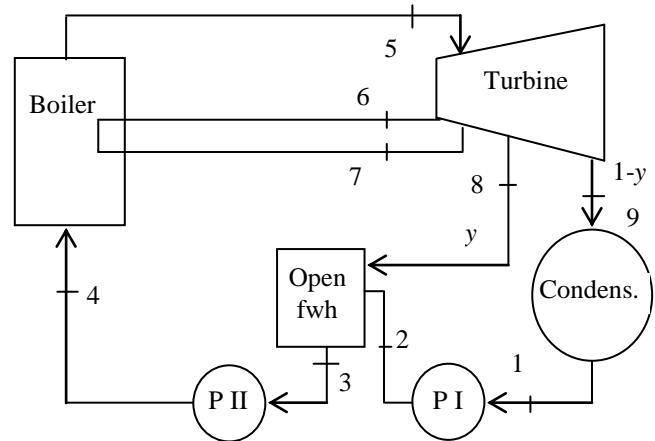

$$P_5 = 10 \text{ MPa} \left. \begin{array}{l} h_5 = 3375.1 \text{ kJ/kg} \\ T_5 = 500^\circ\text{C} \end{array} \right\} s_5 = 6.5995 \text{ kJ/kg} \cdot \text{K}$$

$$P_6 = 1.0 \text{ MPa} \left. \begin{array}{l} h_6 = 2783.8 \text{ kJ/kg} \\ s_6 = s_5 \end{array} \right\}$$

$$P_7 = 1.0 \text{ MPa} \left. \begin{array}{l} h_7 = 3479.1 \text{ kJ/kg} \\ T_7 = 500^\circ\text{C} \end{array} \right\} s_7 = 7.7642 \text{ kJ/kg} \cdot \text{K}$$

$$P_8 = 0.6 \text{ MPa} \left. \begin{array}{l} h_8 = 3310.2 \text{ kJ/kg} \\ s_8 = s_7 \end{array} \right\}$$

$$P_9 = 15 \text{ kPa} \left. \begin{array}{l} x_9 = \frac{s_9 - s_f}{s_{fg}} = \frac{7.7642 - 0.7549}{7.2522} = 0.9665 \\ s_9 = s_7 \end{array} \right\} h_9 = h_f + x_9 h_{fg} = 225.94 + (0.9665)(2372.3) = 2518.8 \text{ kJ/kg}$$

The fraction of steam extracted is determined from the steady-flow energy balance equation applied to the feedwater heaters. Noting that $\dot{Q} \cong \dot{W} \cong \Delta ke \cong \Delta pe \cong 0$,

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\phi^0(\text{steady})}{=} 0 \rightarrow \dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \longrightarrow \dot{m}_8 h_8 + \dot{m}_2 h_2 = \dot{m}_3 h_3 \longrightarrow y h_8 + (1-y) h_2 = 1(h_3)$$

where y is the fraction of steam extracted from the turbine ($= \dot{m}_8 / \dot{m}_3$). Solving for y ,

$$y = \frac{h_3 - h_2}{h_8 - h_2} = \frac{670.38 - 226.53}{3310.2 - 226.53} = \mathbf{0.144}$$

(b) The thermal efficiency is determined from

$$q_{\text{in}} = (h_5 - h_4) + (h_7 - h_6) = (3375.1 - 680.73) + (3479.1 - 2783.8) = 3389.7 \text{ kJ/kg}$$

$$q_{\text{out}} = (1-y)(h_9 - h_1) = (1-0.144)(2518.8 - 225.94) = 1962.7 \text{ kJ/kg}$$

and $\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{1962.7 \text{ kJ/kg}}{3389.7 \text{ kJ/kg}} = \mathbf{42.1\%}$

10-97 A nonideal reheat-regenerative Rankine cycle with one open feedwater heater is considered. The fraction of steam extracted for regeneration and the thermal efficiency of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis

(a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 15 \text{ kPa} = 225.94 \text{ kJ/kg}$$

$$\nu_1 = \nu_f @ 15 \text{ kPa} = 0.001014 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{pI, \text{in}} &= \nu_1 (P_2 - P_1) \\ &= (0.001014 \text{ m}^3/\text{kg})(600 - 15 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 0.59 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{pI, \text{in}} = 225.94 + 0.59 = 226.54 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 0.6 \text{ MPa} \\ \text{sat. liquid} \end{array} \right\} \begin{array}{l} h_3 = h_f @ 0.6 \text{ MPa} = 670.38 \text{ kJ/kg} \\ \nu_3 = \nu_f @ 0.6 \text{ MPa} = 0.001101 \text{ m}^3/\text{kg} \end{array}$$

$$\begin{aligned} w_{pII, \text{in}} &= \nu_3 (P_4 - P_3) \\ &= (0.001101 \text{ m}^3/\text{kg})(10,000 - 600 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 10.35 \text{ kJ/kg} \end{aligned}$$

$$h_4 = h_3 + w_{pII, \text{in}} = 670.38 + 10.35 = 680.73 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_5 = 10 \text{ MPa} \\ T_5 = 500^\circ\text{C} \end{array} \right\} \begin{array}{l} h_5 = 3375.1 \text{ kJ/kg} \\ s_5 = 6.5995 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_{6s} = 1.0 \text{ MPa} \\ s_{6s} = s_5 \end{array} \right\} h_{6s} = 2783.8 \text{ kJ/kg}$$

$$\begin{aligned} \eta_T &= \frac{h_5 - h_6}{h_5 - h_{6s}} \longrightarrow h_6 = h_5 - \eta_T (h_5 - h_{6s}) \\ &= 3375.1 - (0.84)(3375.1 - 2783.8) \\ &= 2878.4 \text{ kJ/kg} \end{aligned}$$

$$\left. \begin{array}{l} P_7 = 1.0 \text{ MPa} \\ T_7 = 500^\circ\text{C} \end{array} \right\} \begin{array}{l} h_7 = 3479.1 \text{ kJ/kg} \\ s_7 = 7.7642 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_{8s} = 0.6 \text{ MPa} \\ s_{8s} = s_7 \end{array} \right\} h_{8s} = 3310.2 \text{ kJ/kg}$$

$$\begin{aligned} \eta_T &= \frac{h_7 - h_8}{h_7 - h_{8s}} \longrightarrow h_8 = h_7 - \eta_T (h_7 - h_{8s}) = 3479.1 - (0.84)(3479.1 - 3310.2) \\ &= 3337.2 \text{ kJ/kg} \end{aligned}$$

$$P_{9s} = 15 \text{ kPa} \left\{ \begin{array}{l} x_{9s} = \frac{s_{9s} - s_f}{s_{fg}} = \frac{7.7642 - 0.7549}{7.2522} = 0.9665 \\ s_{9s} = s_7 \end{array} \right. \quad h_{9s} = h_f + x_{9s}h_{fg} = 225.94 + (0.9665)(2372.3) = 2518.8 \text{ kJ/kg}$$

$$\eta_T = \frac{h_7 - h_9}{h_7 - h_{9s}} \longrightarrow h_9 = h_7 - \eta_T(h_7 - h_{9s}) = 3479.1 - (0.84)(3479.1 - 2518.8) = 2672.5 \text{ kJ/kg}$$

The fraction of steam extracted is determined from the steady-flow energy balance equation applied to the feedwater heaters. Noting that $\dot{Q} \cong \dot{W} \cong \Delta ke \cong \Delta pe \cong 0$,

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \stackrel{\phi^0(\text{steady})}{=} 0 \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \longrightarrow \dot{m}_8 h_8 + \dot{m}_2 h_2 = \dot{m}_3 h_3 \longrightarrow y h_8 + (1 - y) h_2 = 1(h_3) \end{aligned}$$

where y is the fraction of steam extracted from the turbine ($= \dot{m}_8 / \dot{m}_3$). Solving for y ,

$$y = \frac{h_3 - h_2}{h_8 - h_2} = \frac{670.38 - 226.53}{3335.3 - 226.53} = \mathbf{0.1427}$$

(b) The thermal efficiency is determined from

$$\begin{aligned} q_{\text{in}} &= (h_5 - h_4) + (h_7 - h_6) \\ &= (3375.1 - 680.73) + (3479.1 - 2878.4) = 3295.1 \text{ kJ/kg} \\ q_{\text{out}} &= (1 - y)(h_9 - h_1) = (1 - 0.1427)(2672.5 - 225.94) = 2097.2 \text{ kJ/kg} \end{aligned}$$

and

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{2097.2 \text{ kJ/kg}}{3295.1 \text{ kJ/kg}} = \mathbf{36.4\%}$$

10-98 A cogeneration plant is to produce power and process heat. There are two turbines in the cycle: a high-pressure turbine and a low-pressure turbine. The temperature, pressure, and mass flow rate of steam at the inlet of high-pressure turbine are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the steam tables (Tables A-4, A-5, and A-6),

$$\begin{aligned}
 P_4 = 1.4 \text{ MPa} \left. \begin{array}{l} h_4 = h_g @ 1.4 \text{ MPa} = 2788.9 \text{ kJ/kg} \\ \text{sat. vapor} \end{array} \right\} s_4 = s_g @ 1.4 \text{ MPa} = 6.4675 \text{ kJ/kg} \cdot \text{K} \\
 x_{5s} = \frac{s_{4s} - s_f}{s_{fg}} = \frac{6.4675 - 0.6492}{7.4996} = 0.7758 \\
 P_5 = 10 \text{ kPa} \left. \begin{array}{l} h_{5s} = h_f + x_{5s} h_{fg} \\ s_{5s} = s_4 \end{array} \right\} \begin{aligned} &= 191.81 + (0.7758)(2392.1) \\ &= 2047.6 \text{ kJ/kg} \end{aligned} \\
 \eta_T = \frac{h_4 - h_5}{h_4 - h_{5s}} \longrightarrow h_5 = h_4 - \eta_T (h_4 - h_{5s}) \\
 = 2788.9 - (0.80)(2788.9 - 2047.6) \\
 = 2195.8 \text{ kJ/kg}
 \end{aligned}$$

and

$$\begin{aligned}
 w_{\text{turb,low}} &= h_4 - h_5 = 2788.9 - 2195.8 = 593.0 \text{ kJ/kg} \\
 \dot{m}_{\text{lowturb}} &= \frac{\dot{W}_{\text{turb,II}}}{w_{\text{turb,low}}} = \frac{1500 \text{ kJ/s}}{593.0 \text{ kJ/kg}} = 2.529 \text{ kg/s} = 151.7 \text{ kg/min}
 \end{aligned}$$

Therefore ,

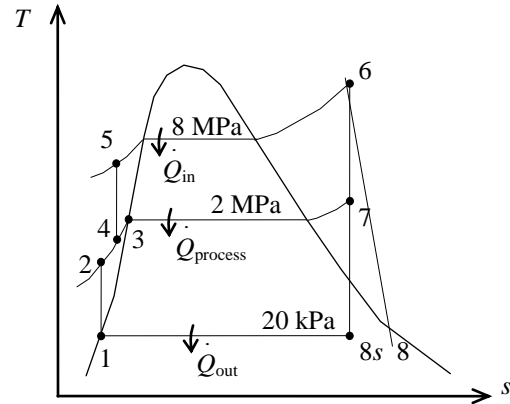

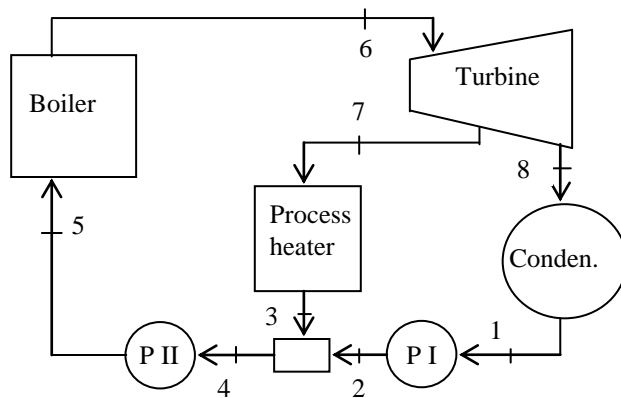

$$\begin{aligned}
 \dot{m}_{\text{total}} &= 1000 + 151.7 = 1152 \text{ kg/min} = \mathbf{19.20 \text{ kg/s}} \\
 w_{\text{turb,high}} &= \frac{\dot{W}_{\text{turb,I}}}{\dot{m}_{\text{high,turb}}} = \frac{5500 \text{ kJ/s}}{19.20 \text{ kg/s}} = 286.5 \text{ kJ/kg} = h_3 - h_4 \\
 h_3 &= w_{\text{turb,high}} + h_4 = 286.5 + 2788.9 = 3075.4 \text{ kJ/kg} \\
 \eta_T &= \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow h_{4s} = h_3 - (h_3 - h_4) / \eta_T \\
 &= 3075.4 - (3075.4 - 2788.9) / (0.85) \\
 &= 2738.3 \text{ kJ/kg} \\
 P_{4s} = 1.4 \text{ MPa} \left. \begin{array}{l} x_{4s} = \frac{h_{4s} - h_f}{h_{fg}} = \frac{2738.3 - 829.96}{1958.9} = 0.9742 \\ s_{4s} = s_3 \end{array} \right\} s_{4s} = s_f + x_{4s} s_{fg} = 2.2835 + (0.9742)(4.1840) = 6.3595 \text{ kJ/kg} \cdot \text{K}
 \end{aligned}$$

Then from the tables or the software, the turbine inlet temperature and pressure becomes

$$\begin{aligned}
 h_3 = 3075.4 \text{ kJ/kg} \left. \begin{array}{l} P_3 = \mathbf{6.40 \text{ MPa}} \\ s_3 = 6.3595 \text{ kJ/kg} \cdot \text{K} \end{array} \right\} T_3 = \mathbf{365^\circ\text{C}}
 \end{aligned}$$

10-99 A cogeneration plant is to generate power and process heat. Part of the steam extracted from the turbine at a relatively high pressure is used for process heating. The rate of process heat, the net power produced, and the utilization factor of the plant are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 20 \text{ kPa} = 251.42 \text{ kJ/kg}$$

$$\nu_1 = \nu_f @ 20 \text{ kPa} = 0.001017 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{pI, \text{in}} &= \nu_1 (P_2 - P_1) / \eta_p \\ &= (0.001017 \text{ m}^3/\text{kg}) (2000 - 20 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) / 0.88 \\ &= 2.29 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{pI, \text{in}} = 251.42 + 2.29 = 253.71 \text{ kJ/kg}$$

$$h_3 = h_f @ 2 \text{ MPa} = 908.47 \text{ kJ/kg}$$

Mixing chamber:

$$\dot{m}_3 h_3 + \dot{m}_2 h_2 = \dot{m}_4 h_4$$

$$(4 \text{ kg/s})(908.47 \text{ kJ/kg}) + (11 - 4 \text{ kg/s})(253.71 \text{ kJ/kg}) = (11 \text{ kg/s})h_4 \longrightarrow h_4 = 491.81 \text{ kJ/kg}$$

$$\nu_4 \cong \nu_f @ h_f = 491.81 \text{ kJ/kg} = 0.001058 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{pII, \text{in}} &= \nu_4 (P_5 - P_4) / \eta_p \\ &= (0.001058 \text{ m}^3/\text{kg}) (8000 - 2000 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) / 0.88 \\ &= 7.21 \text{ kJ/kg} \end{aligned}$$

$$h_5 = h_4 + w_{pII, \text{in}} = 491.81 + 7.21 = 499.02 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_6 = 8 \text{ MPa} \\ T_6 = 500^\circ\text{C} \end{array} \right\} \begin{array}{l} h_6 = 3399.5 \text{ kJ/kg} \\ s_6 = 6.7266 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_7 = 2 \text{ MPa} \\ s_7 = s_6 \end{array} \right\} h_{7s} = 3000.4 \text{ kJ/kg}$$

$$\eta_T = \frac{h_6 - h_7}{h_6 - h_{7s}} \longrightarrow h_7 = h_6 - \eta_T (h_6 - h_{7s}) = 3399.5 - (0.88)(3399.5 - 3000.4) = 3048.3 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_8 = 20 \text{ kPa} \\ s_8 = s_6 \end{array} \right\} h_{8s} = 2215.5 \text{ kJ/kg}$$

$$\eta_T = \frac{h_6 - h_8}{h_6 - h_{8s}} \longrightarrow h_8 = h_6 - \eta_T (h_6 - h_{8s}) = 3399.5 - (0.88)(3399.5 - 2215.5) = 2357.6 \text{ kJ/kg}$$

Then,

$$\dot{Q}_{\text{process}} = \dot{m}_7 (h_7 - h_3) = (4 \text{ kg/s})(3048.3 - 908.47) \text{ kJ/kg} = \mathbf{8559 \text{ kW}}$$

(b) Cycle analysis:

$$\begin{aligned} \dot{W}_{\text{T,out}} &= \dot{m}_7 (h_6 - h_7) + \dot{m}_8 (h_6 - h_8) \\ &= (4 \text{ kg/s})(3399.5 - 3048.3) \text{ kJ/kg} + (7 \text{ kg/s})(3399.5 - 2357.6) \text{ kJ/kg} \\ &= 8698 \text{ kW} \end{aligned}$$

$$\dot{W}_{\text{p,in}} = \dot{m}_1 w_{\text{pI,in}} + \dot{m}_4 w_{\text{pII,in}} = (7 \text{ kg/s})(2.29 \text{ kJ/kg}) + (11 \text{ kg/s})(7.21 \text{ kJ/kg}) = 95 \text{ kW}$$

$$\dot{W}_{\text{net}} = \dot{W}_{\text{T,out}} - \dot{W}_{\text{p,in}} = 8698 - 95 = \mathbf{8603 \text{ kW}}$$

(c) Then,

$$\dot{Q}_{\text{in}} = \dot{m}_5 (h_6 - h_5) = (11 \text{ kg/s})(3399.5 - 499.02) = 31,905 \text{ kW}$$

and

$$\varepsilon_u = \frac{\dot{W}_{\text{net}} + \dot{Q}_{\text{process}}}{\dot{Q}_{\text{in}}} = \frac{8603 + 8559}{31,905} = 0.538 = \mathbf{53.8\%}$$

10-100 A cogeneration power plant is modified with reheat and that produces 3 MW of power and supplies 7 MW of process heat. The rate of heat input in the boiler and the fraction of steam extracted for process heating are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 15 \text{ kPa} = 225.94 \text{ kJ/kg}$$

$$h_2 \cong h_1$$

$$h_3 = h_f @ 120^\circ\text{C} = 503.81 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_6 = 8 \text{ MPa} \\ T_6 = 500^\circ\text{C} \end{array} \right\} \begin{array}{l} h_6 = 3399.5 \text{ kJ/kg} \\ s_6 = 6.7266 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_7 = 1 \text{ MPa} \\ s_7 = s_6 \end{array} \right\} h_7 = 2843.7 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_8 = 1 \text{ MPa} \\ T_8 = 500^\circ\text{C} \end{array} \right\} \begin{array}{l} h_8 = 3479.1 \text{ kJ/kg} \\ s_8 = 7.7642 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$x_9 = \frac{s_9 - s_f}{s_{fg}} = \frac{7.7642 - 0.7549}{7.2522} = 0.9665$$

$$\left. \begin{array}{l} P_9 = 15 \text{ kPa} \\ s_9 = s_8 \end{array} \right\} \begin{array}{l} h_9 = h_f + x_9 h_{fg} = 225.94 + (0.9665)(2372.3) \\ = 2518.8 \text{ kJ/kg} \end{array}$$

The mass flow rate through the process heater is

$$\dot{m}_3 = \frac{\dot{Q}_{\text{process}}}{h_7 - h_3} = \frac{7,000 \text{ kJ/s}}{(2843.7 - 503.81) \text{ kJ/kg}} = 2.992 \text{ kg/s}$$

Also,

$$\dot{W}_T = \dot{m}_6(h_6 - h_7) + \dot{m}_9(h_8 - h_9) = \dot{m}_6(h_6 - h_7) + (\dot{m}_6 - 2.992)(h_8 - h_9)$$

$$3000 \text{ kJ/s} = \dot{m}_6(3399.5 - 2843.7) + (\dot{m}_6 - 2.992)(3479.1 - 2518.8)$$

It yields $\dot{m}_6 = 3.873 \text{ kg/s}$

and $\dot{m}_9 = \dot{m}_6 - \dot{m}_3 = 3.873 - 2.992 = 0.881 \text{ kg/s}$

Mixing chamber:

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\text{no (steady)}}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \quad \longrightarrow \quad \dot{m}_4 h_4 = \dot{m}_2 h_2 + \dot{m}_3 h_3$$

$$\text{or, } h_4 \cong h_5 = \frac{\dot{m}_2 h_2 + \dot{m}_3 h_3}{\dot{m}_4} = \frac{(0.881)(225.94) + (2.992)(503.81)}{3.873} = 440.60 \text{ kJ/kg}$$

Then,

$$\begin{aligned} \dot{Q}_{\text{in}} &= \dot{m}_6(h_6 - h_5) + \dot{m}_9(h_8 - h_7) \\ &= (3.873 \text{ kg/s})(3399.5 - 440.60 \text{ kJ/kg}) + (0.881 \text{ kg/s})(3479.1 - 2843.7 \text{ kJ/kg}) \\ &= \mathbf{12,020 \text{ kW}} \end{aligned}$$

(b) The fraction of steam extracted for process heating is

$$y = \frac{\dot{m}_3}{\dot{m}_{\text{total}}} = \frac{2.992 \text{ kg/s}}{3.873 \text{ kg/s}} = \mathbf{77.3\%}$$

10-101E A combined gas-steam power cycle uses a simple gas turbine for the topping cycle and simple Rankine cycle for the bottoming cycle. The thermal efficiency of the cycle is to be determined.

Assumptions 1 Steady operating conditions exist. **2** The air-standard assumptions are applicable for Brayton cycle. **3** Kinetic and potential energy changes are negligible. **4** Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 0.240$ Btu/lbm·R and $k = 1.4$ (Table A-2Ea).

Analysis Working around the topping cycle gives the following results:

$$T_{6s} = T_5 \left(\frac{P_6}{P_5} \right)^{(k-1)/k} = (540 \text{ R})(10)^{0.4/1.4} = 1043 \text{ R}$$

$$\eta_C = \frac{h_{6s} - h_5}{h_6 - h_5} = \frac{c_p(T_{6s} - T_5)}{c_p(T_6 - T_5)}$$

$$\begin{aligned} \longrightarrow T_6 &= T_5 + \frac{T_{6s} - T_5}{\eta_C} \\ &= 540 + \frac{1043 - 540}{0.90} = 1099 \text{ R} \end{aligned}$$

$$T_{8s} = T_7 \left(\frac{P_8}{P_7} \right)^{(k-1)/k} = (2560 \text{ R}) \left(\frac{1}{10} \right)^{0.4/1.4} = 1326 \text{ R}$$

$$\begin{aligned} \eta_T = \frac{h_7 - h_8}{h_7 - h_{8s}} = \frac{c_p(T_7 - T_8)}{c_p(T_7 - T_{8s})} &\longrightarrow T_8 = T_7 - \eta_T(T_7 - T_{8s}) \\ &= 2560 - (0.90)(2560 - 1326) \\ &= 1449 \text{ R} \end{aligned}$$

$$T_9 = T_{\text{sat @ 800 psia}} + 50 = 978.3 \text{ R} + 50 = 1028 \text{ R}$$

Fixing the states around the bottom steam cycle yields (Tables A-4E, A-5E, A-6E):

$$h_1 = h_f @ 5 \text{ psia} = 130.18 \text{ Btu/lbm}$$

$$v_1 = v_f @ 5 \text{ psia} = 0.01641 \text{ ft}^3/\text{lbm}$$

$$\begin{aligned} w_{p,\text{in}} &= v_1(P_2 - P_1) \\ &= (0.01641 \text{ ft}^3/\text{lbm})(800 - 5) \text{ psia} \left(\frac{1 \text{ Btu}}{5.404 \text{ psia} \cdot \text{ft}^3} \right) \\ &= 2.41 \text{ Btu/lbm} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 130.18 + 2.41 = 132.59 \text{ Btu/lbm}$$

$$\left. \begin{array}{l} P_3 = 800 \text{ psia} \\ T_3 = 600^\circ\text{F} \end{array} \right\} \begin{array}{l} h_3 = 1270.9 \text{ Btu/lbm} \\ s_3 = 1.4866 \text{ Btu/lbm} \cdot \text{R} \end{array}$$

$$\left. \begin{array}{l} P_4 = 5 \text{ psia} \\ s_4 = s_3 \end{array} \right\} h_{4s} = 908.6 \text{ Btu/lbm}$$

$$\begin{aligned} \eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} &\longrightarrow h_4 = h_3 - \eta_T(h_3 - h_{4s}) \\ &= 1270.9 - (0.95)(1270.9 - 908.6) \\ &= 926.7 \text{ Btu/lbm} \end{aligned}$$

The net work outputs from each cycle are

$$\begin{aligned} w_{\text{net,gascycle}} &= w_{T,\text{out}} - w_{C,\text{in}} \\ &= c_p(T_7 - T_8) - c_p(T_6 - T_5) \\ &= (0.240 \text{ Btu/lbm} \cdot \text{R})(2560 - 1449 - 1099 + 540) \text{ R} \\ &= 132.5 \text{ Btu/lbm} \end{aligned}$$

$$\begin{aligned}
 w_{\text{net, steam cycle}} &= w_{T,\text{out}} - w_{P,\text{in}} \\
 &= (h_3 - h_4) - w_{P,\text{in}} \\
 &= (1270.9 - 926.7) - 2.41 \\
 &= 341.8 \text{ Btu/lbm}
 \end{aligned}$$

An energy balance on the heat exchanger gives

$$\dot{m}_a c_p (T_8 - T_9) = \dot{m}_w (h_3 - h_2) \longrightarrow \dot{m}_w = \frac{c_p (T_8 - T_9)}{h_3 - h_2} \dot{m}_a = \frac{(0.240)(1449 - 1028)}{1270.9 - 132.59} = 0.08876 \dot{m}_a$$

That is, 1 lbm of exhaust gases can heat only 0.08876 lbm of water. Then the heat input, the heat output and the thermal efficiency are

$$\begin{aligned}
 q_{\text{in}} &= \frac{\dot{m}_a}{\dot{m}_a} c_p (T_7 - T_6) = (0.240 \text{ Btu/lbm} \cdot \text{R})(2560 - 1099)\text{R} = 350.6 \text{ Btu/lbm} \\
 q_{\text{out}} &= \frac{\dot{m}_a}{\dot{m}_a} c_p (T_9 - T_5) + \frac{\dot{m}_w}{\dot{m}_a} (h_4 - h_1) \\
 &= 1 \times (0.240 \text{ Btu/lbm} \cdot \text{R})(1028 - 540)\text{R} + 0.08876 \times (926.7 - 130.18) \text{ Btu/lbm} \\
 &= 187.8 \text{ Btu/lbm} \\
 \eta_{\text{th}} &= 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{187.8}{350.6} = \mathbf{0.4643}
 \end{aligned}$$

10-102E A combined gas-steam power cycle uses a simple gas turbine for the topping cycle and simple Rankine cycle for the bottoming cycle. The thermal efficiency of the cycle is to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable for Brayton cycle. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 0.240 \text{ Btu/lbm}\cdot\text{R}$ and $k = 1.4$ (Table A-2Ea).

Analysis Working around the topping cycle gives the following results:

$$T_{6s} = T_5 \left(\frac{P_6}{P_5} \right)^{(k-1)/k} = (540 \text{ R})(10)^{0.4/1.4} = 1043 \text{ R}$$

$$\eta_C = \frac{h_{6s} - h_5}{h_6 - h_5} = \frac{c_p(T_{6s} - T_5)}{c_p(T_6 - T_5)}$$

$$\begin{aligned} \longrightarrow T_6 &= T_5 + \frac{T_{6s} - T_5}{\eta_C} \\ &= 540 + \frac{1043 - 540}{0.90} = 1099 \text{ R} \end{aligned}$$

$$T_{8s} = T_7 \left(\frac{P_8}{P_7} \right)^{(k-1)/k} = (2560 \text{ R}) \left(\frac{1}{10} \right)^{0.4/1.4} = 1326 \text{ R}$$

$$\begin{aligned} \eta_T &= \frac{h_7 - h_8}{h_7 - h_{8s}} = \frac{c_p(T_7 - T_8)}{c_p(T_7 - T_{8s})} \longrightarrow T_8 = T_7 - \eta_T(T_7 - T_{8s}) \\ &= 2560 - (0.90)(2560 - 1326) \\ &= 1449 \text{ R} \end{aligned}$$

$$T_9 = T_{\text{sat}@800\text{psia}} + 50 = 978.3 \text{ R} + 50 = 1028 \text{ R}$$

Fixing the states around the bottom steam cycle yields (Tables A-4E, A-5E, A-6E):

$$h_1 = h_f @ 10 \text{ psia} = 161.25 \text{ Btu/lbm}$$

$$v_1 = v_f @ 10 \text{ psia} = 0.01659 \text{ ft}^3/\text{lbm}$$

$$\begin{aligned} w_{p,\text{in}} &= v_1(P_2 - P_1) \\ &= (0.01659 \text{ ft}^3/\text{lbm})(800 - 10) \text{ psia} \left(\frac{1 \text{ Btu}}{5.404 \text{ psia}\cdot\text{ft}^3} \right) \\ &= 2.43 \text{ Btu/lbm} \end{aligned}$$

$$h_2 = h_1 + w_{p,\text{in}} = 161.25 + 2.43 = 163.7 \text{ Btu/lbm}$$

$$\left. \begin{array}{l} P_3 = 800 \text{ psia} \\ T_3 = 600^\circ\text{F} \end{array} \right\} \begin{array}{l} h_3 = 1270.9 \text{ Btu/lbm} \\ s_3 = 1.4866 \text{ Btu/lbm}\cdot\text{R} \end{array}$$

$$\left. \begin{array}{l} P_4 = 10 \text{ psia} \\ s_4 = s_3 \end{array} \right\} h_{4s} = 946.6 \text{ Btu/lbm}$$

$$\begin{aligned} \eta_T &= \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow h_4 = h_3 - \eta_T(h_3 - h_{4s}) \\ &= 1270.9 - (0.95)(1270.9 - 946.6) \\ &= 962.8 \text{ Btu/lbm} \end{aligned}$$

The net work outputs from each cycle are

$$\begin{aligned}
 w_{\text{net, gas cycle}} &= w_{T,\text{out}} - w_{C,\text{in}} \\
 &= c_p (T_7 - T_8) - c_p (T_6 - T_5) \\
 &= (0.240 \text{ Btu/lbm} \cdot \text{R})(2560 - 1449 - 1099 + 540)\text{R} \\
 &= 132.5 \text{ Btu/lbm}
 \end{aligned}$$

$$\begin{aligned}
 w_{\text{net, steam cycle}} &= w_{T,\text{out}} - w_{P,\text{in}} \\
 &= (h_3 - h_4) - w_{P,\text{in}} \\
 &= (1270.9 - 962.8) - 2.43 \\
 &= 305.7 \text{ Btu/lbm}
 \end{aligned}$$

An energy balance on the heat exchanger gives

$$\dot{m}_a c_p (T_8 - T_9) = \dot{m}_w (h_3 - h_2) \longrightarrow \dot{m}_w = \frac{c_p (T_8 - T_9)}{h_3 - h_2} \dot{m}_a = \frac{(0.240)(1449 - 1028)}{1270.9 - 163.7} = 0.09126 \dot{m}_a$$

That is, 1 lbm of exhaust gases can heat only 0.09126 lbm of water. Then the heat input, the heat output and the thermal efficiency are

$$\begin{aligned}
 q_{\text{in}} &= \frac{\dot{m}_a}{\dot{m}_a} c_p (T_7 - T_6) = (0.240 \text{ Btu/lbm} \cdot \text{R})(2560 - 1099)\text{R} = 350.6 \text{ Btu/lbm} \\
 q_{\text{out}} &= \frac{\dot{m}_a}{\dot{m}_a} c_p (T_9 - T_5) + \frac{\dot{m}_w}{\dot{m}_a} (h_4 - h_1) \\
 &= 1 \times (0.240 \text{ Btu/lbm} \cdot \text{R})(1028 - 540)\text{R} + 0.09126 \times (962.8 - 161.25) \text{ Btu/lbm} \\
 &= 190.3 \text{ Btu/lbm} \\
 \eta_{\text{th}} &= 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{190.3}{350.6} = \mathbf{0.4573}
 \end{aligned}$$

When the condenser pressure is increased from 5 psia to 10 psia, the thermal efficiency is decreased from 0.4643 to 0.4573.

10-103E A combined gas-steam power cycle uses a simple gas turbine for the topping cycle and simple Rankine cycle for the bottoming cycle. The cycle supplies a specified rate of heat to the buildings during winter. The mass flow rate of air and the net power output from the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air-standard assumptions are applicable to Brayton cycle. 3 Kinetic and potential energy changes are negligible. 4 Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 0.240 \text{ Btu/lbm}\cdot\text{R}$ and $k = 1.4$ (Table A-2Ea).

Analysis The mass flow rate of water is

$$\dot{m}_w = \frac{\dot{Q}_{\text{buildings}}}{h_4 - h_1} = \frac{2 \times 10^6 \text{ Btu/h}}{(962.8 - 161.25) \text{ Btu/lbm}} = 2495 \text{ lbm/h}$$

The mass flow rate of air is then

$$\dot{m}_a = \frac{\dot{m}_w}{0.09126} = \frac{2495}{0.09126} = \mathbf{27,340 \text{ lbm/h}}$$

The power outputs from each cycle are

$$\begin{aligned} \dot{W}_{\text{net, gas cycle}} &= \dot{m}_a (w_{T,\text{out}} - w_{C,\text{in}}) \\ &= \dot{m}_a c_p (T_7 - T_8) - \dot{m}_a c_p (T_6 - T_5) \\ &= (27,340 \text{ lbm/h})(0.240 \text{ Btu/lbm}\cdot\text{R})(2560 - 1449 - 1099 + 540) \text{ R} \left(\frac{1 \text{ kW}}{3412.14 \text{ Btu/h}} \right) \\ &= 1062 \text{ kW} \end{aligned}$$

$$\begin{aligned} \dot{W}_{\text{net, steam cycle}} &= \dot{m}_a (w_{T,\text{out}} - w_{P,\text{in}}) \\ &= \dot{m}_a (h_3 - h_4 - w_{P,\text{in}}) \\ &= (2495 \text{ lbm/h})(1270.9 - 962.8 - 2.43) \left(\frac{1 \text{ kW}}{3412.14 \text{ Btu/h}} \right) \\ &= 224 \text{ kW} \end{aligned}$$

The net electricity production by this cycle is then

$$\dot{W}_{\text{net}} = 1062 + 224 = \mathbf{1286 \text{ kW}}$$

10-104 A combined gas-steam power plant is considered. The topping cycle is an ideal gas-turbine cycle and the bottoming cycle is an ideal reheat Rankine cycle. The mass flow rate of air in the gas-turbine cycle, the rate of total heat input, and the thermal efficiency of the combined cycle are to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible. **3** Air is an ideal gas with variable specific heats.

Analysis (a) The analysis of gas cycle yields

$$T_7 = 310 \text{ K} \longrightarrow h_7 = 310.24 \text{ kJ/kg}$$

$$P_{r_7} = 1.5546$$

$$P_{r_8} = \frac{P_8}{P_7} P_{r_7} = (12)(1.5546) = 18.66 \longrightarrow h_8 = 630.18 \text{ kJ/kg}$$

$$T_9 = 1400 \text{ K} \longrightarrow h_9 = 1515.42 \text{ kJ/kg}$$

$$P_{r_9} = 450.5$$

$$P_{r_{10}} = \frac{P_{10}}{P_9} P_{r_9} = \left(\frac{1}{12}\right)(450.5) = 37.54 \longrightarrow h_{10} = 768.38 \text{ kJ/kg}$$

$$T_{11} = 520 \text{ K} \longrightarrow h_{11} = 523.63 \text{ kJ/kg}$$

From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 10 \text{ kPa} = 191.81 \text{ kJ/kg}$$

$$v_1 = v_f @ 10 \text{ kPa} = 0.00101 \text{ m}^3/\text{kg}$$

$$w_{p,\text{in}} = v_1(P_2 - P_1) = (0.00101 \text{ m}^3/\text{kg})(12,500 - 10 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3}\right) = 12.62 \text{ kJ/kg}$$

$$h_2 = h_1 + w_{p,\text{in}} = 191.81 + 12.62 = 204.42 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 12.5 \text{ MPa} \\ T_3 = 500^\circ\text{C} \end{array} \right\} \begin{array}{l} h_3 = 3343.6 \text{ kJ/kg} \\ s_3 = 6.4651 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_4 = 2.5 \text{ MPa} \\ s_4 = s_3 \end{array} \right\} h_4 = 2909.6 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_5 = 2.5 \text{ MPa} \\ T_5 = 550^\circ\text{C} \end{array} \right\} \begin{array}{l} h_5 = 3574.4 \text{ kJ/kg} \\ s_5 = 7.4653 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_6 = 10 \text{ kPa} \\ s_6 = s_5 \end{array} \right\} \begin{array}{l} x_6 = \frac{s_6 - s_f}{s_{fg}} = \frac{7.4653 - 0.6492}{7.4996} = 0.9089 \\ h_6 = h_f + x_6 h_{fg} = 191.81 + (0.9089)(2392.1) = 2365.8 \text{ kJ/kg} \end{array}$$

Noting that $\dot{Q} \cong \dot{W} \cong \Delta ke \cong \Delta pe \cong 0$ for the heat exchanger, the steady-flow energy balance equation yields

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}} \longrightarrow \sum \dot{m}_i h_i = \sum \dot{m}_e h_e \longrightarrow \dot{m}_s (h_3 - h_2) = \dot{m}_{\text{air}} (h_{10} - h_{11})$$

$$\dot{m}_{\text{air}} = \frac{h_3 - h_2}{h_{10} - h_{11}} \dot{m}_s = \frac{3343.6 - 204.42}{768.38 - 523.63} (12 \text{ kg/s}) = \mathbf{153.9 \text{ kg/s}}$$

(b) The rate of total heat input is

$$\begin{aligned} \dot{Q}_{\text{in}} &= \dot{Q}_{\text{air}} + \dot{Q}_{\text{reheat}} = \dot{m}_{\text{air}} (h_9 - h_8) + \dot{m}_{\text{reheat}} (h_5 - h_4) \\ &= (153.9 \text{ kg/s})(1515.42 - 630.18) \text{ kJ/kg} + (12 \text{ kg/s})(3574.4 - 2909.6) \text{ kJ/kg} \\ &= 144,200 \text{ kW} \\ &\cong \mathbf{1.44 \times 10^5 \text{ kW}} \end{aligned}$$

(c) The rate of heat rejection and the thermal efficiency are then

$$\begin{aligned} \dot{Q}_{\text{out}} &= \dot{Q}_{\text{out,air}} + \dot{Q}_{\text{out,steam}} = \dot{m}_{\text{air}} (h_{11} - h_7) + \dot{m}_s (h_6 - h_1) \\ &= (153.9 \text{ kg/s})(523.63 - 310.24) \text{ kJ/kg} + (12 \text{ kg/s})(2365.8 - 191.81) \text{ kJ/kg} \\ &= 58,930 \text{ kW} \end{aligned}$$

$$\eta_{\text{th}} = 1 - \frac{\dot{Q}_{\text{out}}}{\dot{Q}_{\text{in}}} = 1 - \frac{58,930 \text{ kW}}{144,200 \text{ kW}} = 0.5913 = \mathbf{59.1\%}$$

10-105 A combined gas-steam power plant is considered. The topping cycle is a gas-turbine cycle and the bottoming cycle is a nonideal reheat Rankine cycle. The mass flow rate of air in the gas-turbine cycle, the rate of total heat input, and the thermal efficiency of the combined cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with variable specific heats.

Analysis (a) The analysis of gas cycle yields (Table A-17)

$$T_7 = 290 \text{ K} \longrightarrow h_7 = 290.16 \text{ kJ/kg}$$

$$P_{r_7} = 1.2311$$

$$P_{r_{8s}} = \frac{P_{8s}}{P_7} P_{r_7} = (8)(1.2311) = 9.849 \longrightarrow h_{8s} = 526.12 \text{ kJ/kg}$$

$$\eta_C = \frac{h_{8s} - h_7}{h_8 - h_7} \longrightarrow h_8 = h_7 + (h_{8s} - h_7)/\eta_C$$

$$= 290.16 + (526.12 - 290.16)/(0.85)$$

$$= 567.76 \text{ kJ/kg}$$

$$T_9 = 1400 \text{ K} \longrightarrow h_9 = 1515.42 \text{ kJ/kg}$$

$$P_{r_9} = 450.5$$

$$P_{r_{10s}} = \frac{P_{10s}}{P_9} P_{r_9} = \left(\frac{1}{8}\right)(450.5) = 56.3 \longrightarrow h_{10s} = 860.35 \text{ kJ/kg}$$

$$\eta_T = \frac{h_9 - h_{10}}{h_9 - h_{10s}} \longrightarrow h_{10} = h_9 - \eta_T(h_9 - h_{10s})$$

$$= 1515.42 - (0.90)(1515.42 - 860.35)$$

$$= 925.86 \text{ kJ/kg}$$

$$T_{11} = 520 \text{ K} \longrightarrow h_{11} = 523.63 \text{ kJ/kg}$$

From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 10 \text{ kPa} = 191.81 \text{ kJ/kg}$$

$$v_1 = v_f @ 10 \text{ kPa} = 0.00101 \text{ m}^3/\text{kg}$$

$$w_{p1,\text{in}} = v_1(P_2 - P_1)$$

$$= (0.00101 \text{ m}^3/\text{kg})(15,000 - 10 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right)$$

$$= 15.14 \text{ kJ/kg}$$

$$h_2 = h_1 + w_{p1,\text{in}} = 191.81 + 15.14 = 206.95 \text{ kJ/kg}$$

$$P_3 = 15 \text{ MPa} \left\{ \begin{array}{l} h_3 = 3157.9 \text{ kJ/kg} \\ s_3 = 6.1428 \text{ kJ/kg} \cdot \text{K} \end{array} \right.$$

$$P_4 = 3 \text{ MPa} \left\{ \begin{array}{l} x_{4s} = \frac{s_{4s} - s_f}{s_{fg}} = \frac{6.1434 - 2.6454}{3.5402} = 0.9880 \\ s_{4s} = s_3 \end{array} \right. \left\{ \begin{array}{l} h_{4s} = h_f + x_{4s} h_{fg} = 1008.3 + (0.9879)(1794.9) = 2781.7 \text{ kJ/kg} \end{array} \right.$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow h_4 = h_3 - \eta_T(h_3 - h_{4s})$$

$$= 3157.9 - (0.90)(3157.9 - 2781.7)$$

$$= 2819.4 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_5 = 3 \text{ MPa} \\ T_5 = 500^\circ\text{C} \end{array} \right\} \begin{array}{l} h_5 = 3457.2 \text{ kJ/kg} \\ s_5 = 7.2359 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_6 = 10 \text{ kPa} \\ s_{6s} = s_5 \end{array} \right\} \begin{array}{l} x_{6s} = \frac{s_{6s} - s_f}{s_{fg}} = \frac{7.2359 - 0.6492}{7.4996} = 0.8783 \\ h_{6s} = h_f + x_{6s} h_{fg} = 191.81 + (0.8782)(2392.1) = 2292.7 \text{ kJ/kg} \end{array}$$

$$\eta_T = \frac{h_5 - h_6}{h_5 - h_{6s}} \longrightarrow h_6 = h_5 - \eta_T (h_5 - h_{6s}) \\ = 3457.2 - (0.90)(3457.2 - 2292.7) \\ = 2409.1 \text{ kJ/kg}$$

Noting that $\dot{Q} \cong \dot{W} \cong \Delta ke \cong \Delta pe \cong 0$ for the heat exchanger, the steady-flow energy balance equation yields

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \stackrel{\neq 0 \text{ (steady)}}{=} 0 \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \longrightarrow \dot{m}_s (h_3 - h_2) = \dot{m}_{\text{air}} (h_{10} - h_{11}) \\ \dot{m}_{\text{air}} &= \frac{h_3 - h_2}{h_{10} - h_{11}} \dot{m}_s = \frac{3157.9 - 206.95}{925.86 - 523.63} (30 \text{ kg/s}) = \mathbf{220.1 \text{ kg/s}} \end{aligned}$$

$$\begin{aligned} (b) \quad \dot{Q}_{\text{in}} &= \dot{Q}_{\text{air}} + \dot{Q}_{\text{reheat}} = \dot{m}_{\text{air}} (h_9 - h_8) + \dot{m}_{\text{reheat}} (h_5 - h_4) \\ &= (220.1 \text{ kg/s})(1515.42 - 567.76) \text{ kJ/kg} + (30 \text{ kg/s})(3457.2 - 2819.4) \text{ kJ/kg} \\ &= \mathbf{227,700 \text{ kW}} \end{aligned}$$

$$\begin{aligned} (c) \quad \dot{Q}_{\text{out}} &= \dot{Q}_{\text{out,air}} + \dot{Q}_{\text{out,steam}} = \dot{m}_{\text{air}} (h_{11} - h_7) + \dot{m}_s (h_6 - h_1) \\ &= (220.1 \text{ kg/s})(523.63 - 290.16) \text{ kJ/kg} + (30 \text{ kg/s})(2409.1 - 191.81) \text{ kJ/kg} \\ &= \mathbf{117,900 \text{ kW}} \end{aligned}$$

$$\eta_{\text{th}} = 1 - \frac{\dot{Q}_{\text{out}}}{\dot{Q}_{\text{in}}} = 1 - \frac{117,900 \text{ kW}}{227,700 \text{ kW}} = 0.482 = \mathbf{48.2\%}$$

10-106 A Rankine steam cycle modified with two closed feedwater heaters and one open feedwater heater is considered. The T - s diagram for the ideal cycle is to be sketched. The fraction of mass extracted for the open feedwater heater y and the cooling water flow temperature rise are to be determined. Also, the rate of heat rejected in the condenser and the thermal efficiency of the plant are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (b) Using the data from the problem statement, the enthalpies at various states are

$$h_1 = h_f @ 20 \text{ kPa} = 251 \text{ kJ/kg}$$

$$h_{15} = h_3 = h_{14} = h_f @ 140 \text{ kPa} = 458 \text{ kJ/kg}$$

$$h_4 = h_f @ 620 \text{ kPa} = 676 \text{ kJ/kg}$$

$$h_6 = h_{12} = h_f @ 1910 \text{ kPa} = 898 \text{ kJ/kg}$$

An energy balance on the open feedwater heater gives

$$yh_9 + (1 - y)h_3 = 1h_4$$

where z is the fraction of steam extracted from the low-pressure turbine. Solving for z ,

$$y = \frac{h_4 - h_3}{h_9 - h_3} = \frac{676 - 458}{3154 - 458} = \mathbf{0.08086}$$

(c) An energy balance on the condenser gives

$$\dot{m}_7[(1 - w - y - z)h_{11} + (w + z)h_{15} - (1 - y)h_7] = \dot{m}_w(h_{w2} - h_{w1}) = \dot{m}_w c_{pw} \Delta T_w$$

Solving for the temperature rise of cooling water, and substituting with correct units,

$$\begin{aligned} \Delta T_w &= \frac{\dot{m}_7[(1 - w - y - z)h_{11} + (w + z)h_{15} - (1 - y)h_7]}{\dot{m}_w c_{pw}} \\ &= \frac{(100)[(1 - 0.0830 - 0.08086 - 0.0655)(2478) + (0.0830 + 0.0655)(458) - (1 - 0.08086)(251)]}{(4200)(4.18)} \\ &= \mathbf{9.95^\circ\text{C}} \end{aligned}$$

(d) The rate of heat rejected in the condenser is

$$\dot{Q}_{\text{out}} = \dot{m}_w c_{pw} \Delta T_w = (4200 \text{ kg/s})(4.18 \text{ kJ/kg} \cdot ^\circ\text{C})(9.95^\circ\text{C}) = \mathbf{174,700 \text{ kW}}$$

The rate of heat input in the boiler is

$$\dot{Q}_{\text{in}} = \dot{m}(h_7 - h_6) = (100 \text{ kg/s})(3900 - 898) \text{ kJ/kg} = 300,200 \text{ kW}$$

The thermal efficiency is then

$$\eta_{\text{th}} = 1 - \frac{\dot{Q}_{\text{out}}}{\dot{Q}_{\text{in}}} = 1 - \frac{174,700 \text{ kW}}{300,200 \text{ kW}} = 0.418 = \mathbf{41.8\%}$$

10-107 A steam power plant operates on an ideal reheat-regenerative Rankine cycle with one reheater and two feedwater heaters, one open and one closed. The fraction of steam extracted from the turbine for the open feedwater heater, the thermal efficiency of the cycle, and the net power output are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis

(a) From the steam tables (Tables A-4, A-5, and A-6),

$$h_1 = h_f @ 5 \text{ kPa} = 137.75 \text{ kJ/kg}$$

$$\nu_1 = \nu_f @ 5 \text{ kPa} = 0.001005 \text{ m}^3/\text{kg}$$

$$\begin{aligned} w_{pI, \text{in}} &= \nu_1 (P_2 - P_1) \\ &= (0.001005 \text{ m}^3/\text{kg})(200 - 5 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 0.20 \text{ kJ/kg} \end{aligned}$$

$$h_2 = h_1 + w_{pI, \text{in}} = 137.75 + 0.20 = 137.95 \text{ kJ/kg}$$

$$\left. \begin{aligned} P_3 &= 0.2 \text{ MPa} \\ \text{sat. liquid} \end{aligned} \right\} \begin{aligned} h_3 &= h_f @ 0.2 \text{ MPa} = 504.71 \text{ kJ/kg} \\ \nu_3 &= \nu_f @ 0.2 \text{ MPa} = 0.001061 \text{ m}^3/\text{kg} \end{aligned}$$

$$\begin{aligned} w_{pII, \text{in}} &= \nu_3 (P_4 - P_3) \\ &= (0.001061 \text{ m}^3/\text{kg})(15,000 - 200 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 15.70 \text{ kJ/kg} \end{aligned}$$

$$h_4 = h_3 + w_{pII, \text{in}} = 504.71 + 15.70 = 520.41 \text{ kJ/kg}$$

$$\left. \begin{aligned} P_6 &= 0.6 \text{ MPa} \\ \text{sat. liquid} \end{aligned} \right\} \begin{aligned} h_6 = h_7 &= h_f @ 0.6 \text{ MPa} = 670.38 \text{ kJ/kg} \\ \nu_6 &= \nu_f @ 0.6 \text{ MPa} = 0.001101 \text{ m}^3/\text{kg} \end{aligned}$$

$$\begin{aligned} T_6 = T_5 &\longrightarrow h_5 = h_6 + \nu_6 (P_5 - P_6) \\ &= 670.38 + (0.001101 \text{ m}^3/\text{kg})(15,000 - 600 \text{ kPa}) \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) \\ &= 686.23 \text{ kJ/kg} \end{aligned}$$

$$\left. \begin{aligned} P_8 &= 15 \text{ MPa} \\ T_8 &= 600^\circ\text{C} \end{aligned} \right\} \begin{aligned} h_8 &= 3583.1 \text{ kJ/kg} \\ s_8 &= 6.6796 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

$$\left. \begin{aligned} P_9 &= 1.0 \text{ MPa} \\ s_9 &= s_8 \end{aligned} \right\} h_9 = 2820.8 \text{ kJ/kg}$$

$$\left. \begin{aligned} P_{10} &= 1.0 \text{ MPa} \\ T_{10} &= 500^\circ\text{C} \end{aligned} \right\} \begin{aligned} h_{10} &= 3479.1 \text{ kJ/kg} \\ s_{10} &= 7.7642 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

$$P_{11} = 0.6 \text{ MPa} \left. \vphantom{P_{11}} \right\} h_{11} = 3310.2 \text{ kJ/kg}$$

$$s_{11} = s_{10}$$

$$P_{12} = 0.2 \text{ MPa} \left. \vphantom{P_{12}} \right\} h_{12} = 3000.9 \text{ kJ/kg}$$

$$s_{12} = s_{10}$$

$$x_{13} = \frac{s_{13} - s_f}{s_{fg}} = \frac{7.7642 - 0.4762}{7.9176}$$

$$P_{13} = 5 \text{ kPa} \left. \vphantom{P_{13}} \right\} h_{13} = h_f + x_{13}h_{fg}$$

$$s_{13} = s_{10} \left. \vphantom{s_{13}} \right\} = 137.75 + (0.9205)(2423.0)$$

$$= 2368.1 \text{ kJ/kg}$$

The fraction of steam extracted is determined from the steady-flow energy balance equation applied to the feedwater heaters. Noting that $\dot{Q} \cong \dot{W} \cong \Delta ke \cong \Delta pe \cong 0$,

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}}^{\phi^0(\text{steady})} = 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \longrightarrow \dot{m}_{11}(h_{11} - h_6) = \dot{m}_5(h_5 - h_4) \longrightarrow y(h_{11} - h_6) = (h_5 - h_4)$$

where y is the fraction of steam extracted from the turbine ($= \dot{m}_{11} / \dot{m}_5$). Solving for y ,

$$y = \frac{h_5 - h_4}{h_{11} - h_6} = \frac{686.23 - 520.41}{3310.2 - 670.38} = 0.06287$$

For the open FWH,

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}}^{\phi^0(\text{steady})} = 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e$$

$$\dot{m}_7 h_7 + \dot{m}_2 h_2 + \dot{m}_{12} h_{12} = \dot{m}_3 h_3$$

$$y h_7 + (1 - y - z) h_2 + z h_{12} = (1) h_3$$

where z is the fraction of steam extracted from the turbine ($= \dot{m}_{12} / \dot{m}_5$) at the second stage. Solving for z ,

$$z = \frac{(h_3 - h_2) - y(h_7 - h_2)}{h_{12} - h_2} = \frac{504.71 - 137.95 - (0.06287)(670.38 - 137.95)}{3000.0 - 137.95} = \mathbf{0.1165}$$

$$(b) \quad q_{\text{in}} = (h_8 - h_5) + (h_{10} - h_9)$$

$$= (3583.1 - 686.23) + (3479.1 - 2820.8) = 3555.3 \text{ kJ/kg}$$

$$q_{\text{out}} = (1 - y - z)(h_{13} - h_1) = (1 - 0.06287 - 0.1165)(2368.0 - 137.75) = 1830.4 \text{ kJ/kg}$$

$$w_{\text{net}} = q_{\text{in}} - q_{\text{out}} = 3555.3 - 1830.4 = 1724.9 \text{ kJ/kg}$$

and

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{1830.4 \text{ kJ/kg}}{3555.3 \text{ kJ/kg}} = \mathbf{48.5\%}$$

$$(c) \quad \dot{W}_{\text{net}} = \dot{m} w_{\text{net}} = (42 \text{ kg/s})(1724.9 \text{ kJ/kg}) = \mathbf{72,447 \text{ kW}}$$

10-108 The effect of the boiler pressure on the performance a simple ideal Rankine cycle is to be investigated.

Analysis The problem is solved using EES, and the solution is given below.

0.4369	12500	903.5	2068

10-112 It is to be demonstrated that the thermal efficiency of a combined gas-steam power plant η_{cc} can be expressed as $\eta_{cc} = \eta_g + \eta_s - \eta_g \eta_s$ where $\eta_g = W_g / Q_{in}$ and $\eta_s = W_s / Q_{g,out}$ are the thermal efficiencies of the gas and steam cycles, respectively, and the efficiency of a combined cycle is to be obtained.

Analysis The thermal efficiencies of gas, steam, and combined cycles can be expressed as

$$\eta_{cc} = \frac{W_{total}}{Q_{in}} = 1 - \frac{Q_{out}}{Q_{in}}$$

$$\eta_g = \frac{W_g}{Q_{in}} = 1 - \frac{Q_{g,out}}{Q_{in}}$$

$$\eta_s = \frac{W_s}{Q_{g,out}} = 1 - \frac{Q_{out}}{Q_{g,out}}$$

where Q_{in} is the heat supplied to the gas cycle, where Q_{out} is the heat rejected by the steam cycle, and where $Q_{g,out}$ is the heat rejected from the gas cycle and supplied to the steam cycle.

Using the relations above, the expression $\eta_g + \eta_s - \eta_g \eta_s$ can be expressed as

$$\begin{aligned} \eta_g + \eta_s - \eta_g \eta_s &= \left(1 - \frac{Q_{g,out}}{Q_{in}}\right) + \left(1 - \frac{Q_{out}}{Q_{g,out}}\right) - \left(1 - \frac{Q_{g,out}}{Q_{in}}\right) \left(1 - \frac{Q_{out}}{Q_{g,out}}\right) \\ &= 1 - \frac{Q_{g,out}}{Q_{in}} + 1 - \frac{Q_{out}}{Q_{g,out}} - 1 + \frac{Q_{g,out}}{Q_{in}} + \frac{Q_{out}}{Q_{g,out}} - \frac{Q_{out}}{Q_{in}} \\ &= 1 - \frac{Q_{out}}{Q_{in}} \\ &= \eta_{cc} \end{aligned}$$

Therefore, the proof is complete. Using the relation above, the thermal efficiency of the given combined cycle is determined to be

$$\eta_{cc} = \eta_g + \eta_s - \eta_g \eta_s = 0.4 + 0.30 - 0.40 \times 0.30 = \mathbf{0.58}$$

10-113 The thermal efficiency of a combined gas-steam power plant η_{cc} can be expressed in terms of the thermal efficiencies of the gas and the steam turbine cycles as $\eta_{cc} = \eta_g + \eta_s - \eta_g \eta_s$. It is to be shown that the value of η_{cc} is greater than either of η_g or η_s .

Analysis By factoring out terms, the relation $\eta_{cc} = \eta_g + \eta_s - \eta_g \eta_s$ can be expressed as

$$\eta_{cc} = \eta_g + \eta_s - \eta_g \eta_s = \eta_g + \underbrace{\eta_s(1 - \eta_g)}_{\substack{\text{Positive since} \\ \eta_g < 1}} > \eta_g$$

or

$$\eta_{cc} = \eta_g + \eta_s - \eta_g \eta_s = \eta_s + \underbrace{\eta_g(1 - \eta_s)}_{\substack{\text{Positive since} \\ \eta_s < 1}} > \eta_s$$

Thus we conclude that the combined cycle is more efficient than either of the gas turbine or steam turbine cycles alone.

10-114 It is to be shown that the exergy destruction associated with a simple ideal Rankine cycle can be expressed as $x_{\text{destroyed}} = q_{\text{in}}(\eta_{\text{th,Carnot}} - \eta_{\text{th}})$, where η_{th} is efficiency of the Rankine cycle and $\eta_{\text{th,Carnot}}$ is the efficiency of the Carnot cycle operating between the same temperature limits.

Analysis The exergy destruction associated with a cycle is given on a unit mass basis as

$$x_{\text{destroyed}} = T_0 \sum \frac{q_R}{T_R}$$

where the direction of q_{in} is determined with respect to the reservoir (positive if to the reservoir and negative if from the reservoir). For a cycle that involves heat transfer only with a source at T_H and a sink at T_0 , the irreversibility becomes

$$\begin{aligned} x_{\text{destroyed}} &= T_0 \left(\frac{q_{\text{out}}}{T_0} - \frac{q_{\text{in}}}{T_H} \right) = q_{\text{out}} - \frac{T_0}{T_H} q_{\text{in}} = q_{\text{in}} \left(\frac{q_{\text{out}}}{q_{\text{in}}} - \frac{T_0}{T_H} \right) \\ &= q_{\text{in}} \left[(1 - \eta_{\text{th}}) - (1 - \eta_{\text{th,C}}) \right] = q_{\text{in}} (\eta_{\text{th,C}} - \eta_{\text{th}}) \end{aligned}$$

10-115 Thermal collection efficiency of a solar collector system is given. The operating temperature of the solar collector for maximum system efficiency is to be determined and an expression for maximum system efficiency is to be developed.

Analysis (a) The overall system efficiency is a product of the solar collector and power plant efficiencies, or

$$\eta = \eta_{\text{sc}} \eta_{\text{th}} = (A - BT_H) \left[F \left(1 - \frac{T_L}{T_H} \right) \right] = F \left(A - BT_H - A \frac{T_L}{T_H} + BT_L \right) \quad (1)$$

The maximum temperature is found when $\frac{d\eta}{dT_H} = 0$, for which the optimal T_H is

$$\frac{d\eta}{dT_H} = -B + A \frac{T_L}{T_H^2} = 0 \longrightarrow T_{H,\text{optimal}} = \sqrt{A \frac{T_L}{B}} \quad (2)$$

(b) Substituting Eq. (2) into Eq. (1) gives the maximum overall system efficiency:

$$\eta_{\text{max}} = F \left(A - B \sqrt{A \frac{T_L}{B}} - A \frac{T_L}{\sqrt{A \frac{T_L}{B}}} + BT_L \right) = F \left(\sqrt{A} - \sqrt{BT_L} \right)^2$$

Discussion A higher value of T_H increases the power plant efficiency but decreases the heat gained from the solar collector, and the converse. This problem illustrates how components integrated to form a system must be mutually adjusted to optimize system performance.

Fundamentals of Engineering (FE) Exam Problems

10-116 Consider a simple ideal Rankine cycle. If the condenser pressure is lowered while keeping turbine inlet state the same, (select the correct statement)

- (a) the turbine work output will decrease.
- (b) the amount of heat rejected will decrease.
- (c) the cycle efficiency will decrease.
- (d) the moisture content at turbine exit will decrease.
- (e) the pump work input will decrease.

Answer (b) the amount of heat rejected will decrease.

10-117 Consider a simple ideal Rankine cycle with fixed boiler and condenser pressures. If the steam is superheated to a higher temperature, (select the correct statement)

- (a) the turbine work output will decrease.
- (b) the amount of heat rejected will decrease.
- (c) the cycle efficiency will decrease.
- (d) the moisture content at turbine exit will decrease.
- (e) the amount of heat input will decrease.

Answer (d) the moisture content at turbine exit will decrease.

10-118 Consider a simple ideal Rankine cycle with fixed boiler and condenser pressures. If the cycle is modified with reheating, (select the correct statement)

- (a) the turbine work output will decrease.
- (b) the amount of heat rejected will decrease.
- (c) the pump work input will decrease.
- (d) the moisture content at turbine exit will decrease.
- (e) the amount of heat input will decrease.

Answer (d) the moisture content at turbine exit will decrease.

10-119 Consider a simple ideal Rankine cycle with fixed boiler and condenser pressures. If the cycle is modified with regeneration that involves one open feed water heater, (select the correct statement per unit mass of steam flowing through the boiler)

- (a) the turbine work output will decrease.
- (b) the amount of heat rejected will increase.
- (c) the cycle thermal efficiency will decrease.
- (d) the quality of steam at turbine exit will decrease.
- (e) the amount of heat input will increase.

Answer (a) the turbine work output will decrease.

10-120 Consider a steady-flow Carnot cycle with water as the working fluid executed under the saturation dome between the pressure limits of 3 MPa and 10 kPa. Water changes from saturated liquid to saturated vapor during the heat addition process. The net work output of this cycle is

- (a) 666 kJ/kg
- (b) 888 kJ/kg
- (c) 1040 kJ/kg
- (d) 1130 kJ/kg
- (e) 1440 kJ/kg

Answer (a) 666 kJ/kg

10-125 An ideal reheat Rankine cycle operates between the pressure limits of 10 kPa and 8 MPa, with reheat occurring at 4 MPa. The temperature of steam at the inlets of both turbines is 500°C, and the enthalpy of steam is 3185 kJ/kg at the exit of the high-pressure turbine, and 2247 kJ/kg at the exit of the low-pressure turbine. Disregarding the pump work, the cycle efficiency is

- (a) 29% (b) 32% (c) 36% (d) 41% (e) 49%

Answer (d) 41%

10-128 Consider a cogeneration power plant modified with regeneration. Steam enters the turbine at 6 MPa and 450°C at a rate of 20 kg/s and expands to a pressure of 0.4 MPa. At this pressure, 60% of the steam is extracted from the turbine, and the remainder expands to a pressure of 10 kPa. Part of the extracted steam is used to heat feedwater in an open feedwater heater. The rest of the extracted steam is used for process heating and leaves the process heater as a saturated liquid at 0.4 MPa. It is subsequently mixed with the feedwater leaving the feedwater heater, and the mixture is pumped to the boiler pressure. The steam in the condenser is cooled and condensed by the cooling water from a nearby river, which enters the the adiabatic condenser at a rate of 463 kg/s.

1. The total power output of the turbine is

- (a) 17.0 MW (b) 8.4 MW (c) 12.2 MW (d) 20.0 MW (e) 3.4 MW

Answer (a) 17.0 MW

2. The temperature rise of the cooling water from the river in the condenser is

- (a) 8.0°C (b) 5.2°C (c) 9.6°C (d) 12.9°C (e) 16.2°C

Answer (a) 8.0°C

3. The mass flow rate of steam through the process heater is

- (a) 1.6 kg/s (b) 3.8 kg/s (c) 5.2 kg/s (d) 7.6 kg/s (e) 10.4 kg/s

Answer (e) 10.4 kg/s

4. The rate of heat supply from the process heater per unit mass of steam passing through it is

- (a) 246 kJ/kg (b) 893 kJ/kg (c) 1344 kJ/kg (d) 1891 kJ/kg (e) 2060 kJ/kg

Answer (e) 2060 kJ/kg

5. The rate of heat transfer to the steam in the boiler is

- (a) 26.0 MJ/s (b) 53.8 MJ/s (c) 39.5 MJ/s (d) 62.8 MJ/s (e) 125.4 MJ/s

Answer (b) 53.8 MJ/s

The Reversed Carnot Cycle

11-1C Because the compression process involves the compression of a liquid-vapor mixture which requires a compressor that will handle two phases, and the expansion process involves the expansion of high-moisture content refrigerant.

11-2C The reversed Carnot cycle serves as a standard against which actual refrigeration cycles can be compared. Also, the COP of the reversed Carnot cycle provides the upper limit for the COP of a refrigeration cycle operating between the specified temperature limits.

11-3 A steady-flow Carnot refrigeration cycle with refrigerant-134a as the working fluid is considered. The coefficient of performance, the amount of heat absorbed from the refrigerated space, and the net work input are to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis (a) Noting that $T_H = 60^\circ\text{C} = 333\text{ K}$ and $T_L = T_{\text{sat}} @ 140\text{ kPa} = -18.77^\circ\text{C} = 254.2\text{ K}$, the COP of this Carnot refrigerator is determined from

$$\text{COP}_{\text{R,C}} = \frac{1}{T_H/T_L - 1} = \frac{1}{(333\text{ K})/(254.2\text{ K}) - 1} = \mathbf{3.227}$$

(b) From the refrigerant tables (Table A-11),

$$h_3 = h_{g@60^\circ\text{C}} = 278.47\text{ kJ/kg}$$

$$h_4 = h_{f@60^\circ\text{C}} = 139.38\text{ kJ/kg}$$

Thus,

$$q_H = h_3 - h_4 = 278.47 - 139.38 = 139.1\text{ kJ/kg}$$

and

$$\frac{q_H}{q_L} = \frac{T_H}{T_L} \longrightarrow q_L = \frac{T_L}{T_H} q_H = \left(\frac{254.2\text{ K}}{333\text{ K}} \right) (139.1\text{ kJ/kg}) = \mathbf{106.2\text{ kJ/kg}}$$

(c) The net work input is determined from

$$w_{\text{net}} = q_H - q_L = 139.1 - 106.2 = \mathbf{32.9\text{ kJ/kg}}$$

11-4E A steady-flow Carnot refrigeration cycle with refrigerant-134a as the working fluid is considered. The coefficient of performance, the quality at the beginning of the heat-absorption process, and the net work input are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) Noting that $T_H = T_{\text{sat @ 90 psia}} = 72.78^\circ\text{F} = 532.8\text{ R}$ and $T_L = T_{\text{sat @ 30 psia}} = 15.37^\circ\text{F} = 475.4\text{ R}$.

$$\text{COP}_{\text{R,C}} = \frac{1}{T_H / T_L - 1} = \frac{1}{(532.8\text{ R}) / (475.4\text{ R}) - 1} = \mathbf{8.28}$$

(b) Process 4-1 is isentropic, and thus

$$s_1 = s_4 = (s_f + x_4 s_{fg})_{\text{@ 90 psia}} = 0.07481 + (0.05)(0.14529) \\ = 0.08208\text{ Btu/lbm}\cdot\text{R}$$

$$x_1 = \left(\frac{s_1 - s_f}{s_{fg}} \right)_{\text{@ 30 psia}} = \frac{0.08208 - 0.03792}{0.18595} = \mathbf{0.237}$$

(c) Remembering that on a T - s diagram the area enclosed represents the net work, and $s_3 = s_g \text{ @ 90 psia} = 0.22011\text{ Btu/lbm}\cdot\text{R}$,

$$w_{\text{net,in}} = (T_H - T_L)(s_3 - s_4) = (72.78 - 15.37)(0.22011 - 0.08208)\text{ Btu/lbm}\cdot\text{R} = \mathbf{7.92\text{ Btu/lbm}}$$

Ideal and Actual Vapor-Compression Refrigeration Cycles

11-5C To make the ideal vapor-compression refrigeration cycle more closely approximate the actual cycle.

11-6C No. Assuming the water is maintained at 10°C in the evaporator, the evaporator pressure will be the saturation pressure corresponding to this pressure, which is 1.2 kPa. It is not practical to design refrigeration or air-conditioning devices that involve such extremely low pressures.

11-7C Allowing a temperature difference of 10°C for effective heat transfer, the condensation temperature of the refrigerant should be 25°C . The saturation pressure corresponding to 25°C is 0.67 MPa. Therefore, the recommended pressure would be 0.7 MPa.

11-8C The area enclosed by the cyclic curve on a T - s diagram represents the net work input for the reversed Carnot cycle, but not so for the ideal vapor-compression refrigeration cycle. This is because the latter cycle involves an irreversible process for which the process path is not known.

11-9C The cycle that involves saturated liquid at 30°C will have a higher COP because, judging from the T - s diagram, it will require a smaller work input for the same refrigeration capacity.

11-10C The minimum temperature that the refrigerant can be cooled to before throttling is the temperature of the sink (the cooling medium) since heat is transferred from the refrigerant to the cooling medium.

11-11E An ice-making machine operates on the ideal vapor-compression refrigeration cycle, using refrigerant-134a as the working fluid. The power input to the ice machine is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis In an ideal vapor-compression refrigeration cycle, the compression process is isentropic, the refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure. From the refrigerant tables (Tables A-12E and A-13E),

$$\left. \begin{array}{l} P_1 = 20 \text{ psia} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} h_1 = h_g @ 20 \text{ psia} = 102.74 \text{ Btu/lbm} \\ s_1 = s_g @ 20 \text{ psia} = 0.22570 \text{ Btu/lbm} \cdot \text{R} \end{array}$$

$$\left. \begin{array}{l} P_2 = 80 \text{ psia} \\ s_2 = s_1 \end{array} \right\} h_2 = 115.01 \text{ Btu/lbm}$$

$$\left. \begin{array}{l} P_3 = 80 \text{ psia} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 80 \text{ psia} = 33.39 \text{ Btu/lbm}$$

$$h_4 \cong h_3 = 33.39 \text{ Btu/lbm (throttling)}$$

The cooling load of this refrigerator is

$$\dot{Q}_L = \dot{m}_{\text{ice}} (\Delta h)_{\text{ice}} = (15/3600 \text{ lbm/s})(169 \text{ Btu/lbm}) = 0.7042 \text{ Btu/s}$$

Then the mass flow rate of the refrigerant and the power input become

$$\dot{m}_R = \frac{\dot{Q}_L}{h_1 - h_4} = \frac{0.7042 \text{ Btu/s}}{(102.74 - 33.39) \text{ Btu/lbm}} = 0.01015 \text{ lbm/s}$$

and

$$\dot{W}_{\text{in}} = \dot{m}_R (h_2 - h_1) = (0.01015 \text{ lbm/s})(115.01 - 102.74) \text{ Btu/lbm} \left(\frac{1 \text{ hp}}{0.7068 \text{ Btu/s}} \right) = \mathbf{0.176 \text{ hp}}$$

11-12E A refrigerator operating on the ideal vapor-compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The increase in the COP if the throttling process were replaced by an isentropic expansion is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis In an ideal vapor-compression refrigeration cycle, the compression process is isentropic, the refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure. From the refrigerant tables (Tables A-11E, A-12E, and A-13E),

$$\left. \begin{array}{l} T_1 = 20^\circ\text{F} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} h_1 = h_g @ 20^\circ\text{F} = 106.00 \text{ Btu/lbm} \\ s_1 = s_g @ 20^\circ\text{F} = 0.22345 \text{ Btu/lbm} \cdot \text{R} \end{array}$$

$$\left. \begin{array}{l} P_2 = 300 \text{ psia} \\ s_2 = s_1 \end{array} \right\} h_2 = 125.70 \text{ Btu/lbm}$$

$$\left. \begin{array}{l} P_3 = 300 \text{ psia} \\ \text{sat. liquid} \end{array} \right\} \begin{array}{l} h_3 = h_f @ 300 \text{ psia} = 66.347 \text{ Btu/lbm} \\ s_3 = s_f @ 300 \text{ psia} = 0.12717 \text{ Btu/lbm} \cdot \text{R} \end{array}$$

$$h_4 \cong h_3 = 66.347 \text{ Btu/lbm} \quad (\text{throttling})$$

$$\left. \begin{array}{l} T_4 = 20^\circ\text{F} \\ s_4 = s_3 \end{array} \right\} \begin{array}{l} h_{4s} = 59.81 \text{ Btu/lbm} \\ x_{4s} = 0.4724 \end{array} \quad (\text{isentropic expansion})$$

The COP of the refrigerator for the throttling case is

$$\text{COP}_R = \frac{q_L}{w_{\text{in}}} = \frac{h_1 - h_4}{h_2 - h_1} = \frac{106.00 - 66.347}{125.70 - 106.00} = \mathbf{2.013}$$

The COP of the refrigerator for the isentropic expansion case is

$$\text{COP}_R = \frac{q_L}{w_{\text{in}}} = \frac{h_1 - h_{4s}}{h_2 - h_1} = \frac{106.00 - 59.81}{125.70 - 106.00} = \mathbf{2.344}$$

The increase in the COP by isentropic expansion is

$$\text{Percent Increase in COP} = \frac{2.344 - 2.013}{2.013} = 0.165 = \mathbf{16.5\%}$$

11-13 An ideal vapor-compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The COP and the power requirement are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis In an ideal vapor-compression refrigeration cycle, the compression process is isentropic, the refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure. From the refrigerant tables (Tables A-11, A-12, and A-13),

$$\left. \begin{array}{l} T_1 = -12^\circ\text{C} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} h_1 = h_g @ -12^\circ\text{C} = 243.34 \text{ kJ/kg} \\ s_1 = s_g @ -12^\circ\text{C} = 0.93925 \text{ kJ/kg}\cdot\text{K} \end{array}$$

$$\left. \begin{array}{l} P_2 = 0.8 \text{ MPa} \\ s_2 = s_1 \end{array} \right\} h_2 = 273.71 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 0.8 \text{ MPa} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 1 \text{ MPa} = 95.48 \text{ kJ/kg}$$

$$h_4 \cong h_3 = 95.48 \text{ kJ/kg} \quad (\text{throttling})$$

The mass flow rate of the refrigerant is

$$\dot{Q}_L = \dot{m}(h_1 - h_4) \longrightarrow \dot{m} = \frac{\dot{Q}_L}{h_1 - h_4} = \frac{150 \text{ kJ/s}}{(243.34 - 95.48) \text{ kJ/kg}} = 1.014 \text{ kg/s}$$

The power requirement is

$$\dot{W}_{\text{in}} = \dot{m}(h_2 - h_1) = (1.014 \text{ kg/s})(273.71 - 243.34) \text{ kJ/kg} = \mathbf{30.81 \text{ kW}}$$

The COP of the refrigerator is determined from its definition,

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} = \frac{150 \text{ kW}}{30.81 \text{ kW}} = \mathbf{4.87}$$

11-14  An ideal vapor-compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The quality of the refrigerant at the end of the throttling process, the COP, and the power input to the compressor are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) In an ideal vapor-compression refrigeration cycle, the compression process is isentropic, the refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure. From the refrigerant tables (Tables A-12 and A-13),

$$\left. \begin{array}{l} P_1 = 140 \text{ kPa} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} h_1 = h_g @ 140 \text{ kPa} = 239.19 \text{ kJ/kg} \\ s_1 = s_g @ 140 \text{ kPa} = 0.94467 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_2 = 0.8 \text{ MPa} \\ s_2 = s_1 \end{array} \right\} h_2 = 275.40 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 0.8 \text{ MPa} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 0.8 \text{ MPa} = 95.48 \text{ kJ/kg}$$

$$h_4 \cong h_3 = 95.48 \text{ kJ/kg (throttling)}$$

The quality of the refrigerant at the end of the throttling process is

$$x_4 = \left(\frac{h_4 - h_f}{h_{fg}} \right) @ 140 \text{ kPa} = \frac{95.48 - 27.06}{212.13} = \mathbf{0.3225}$$

(b) The COP of the refrigerator is determined from its definition,

$$\text{COP}_R = \frac{q_L}{w_{\text{in}}} = \frac{h_1 - h_4}{h_2 - h_1} = \frac{239.19 - 95.48}{275.40 - 239.19} = \mathbf{3.969}$$

(c) The power input to the compressor is determined from

$$\dot{W}_{\text{in}} = \frac{\dot{Q}_L}{\text{COP}_R} = \frac{(300/60) \text{ kW}}{3.969} = \mathbf{1.260 \text{ kW}}$$

11-15 Problem 11-14 is reconsidered. The effect of evaporator pressure on the COP and the power input is to be investigated.

Analysis The problem is solved using EES, and the solution is given below.

COP vs Compressor Efficiency for R134a

11-16 A nonideal vapor-compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The quality of the refrigerant at the end of the throttling process, the COP, the power input to the compressor, and the irreversibility rate associated with the compression process are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) The refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure. From the refrigerant tables (Tables A-12 and A-13),

$$\begin{aligned} P_1 = 140 \text{ kPa} & \left. \begin{aligned} h_1 &= h_g @ 140 \text{ kPa} = 239.19 \text{ kJ/kg} \\ \text{sat. vapor} & \left. \begin{aligned} s_1 &= s_g @ 140 \text{ kPa} = 0.94467 \text{ kJ/kg} \cdot \text{K} \end{aligned} \right\} \end{aligned} \right\} \\ P_2 = 0.8 \text{ MPa} & \left. \begin{aligned} h_{2s} &= 275.40 \text{ kJ/kg} \\ s_{2s} &= s_1 \end{aligned} \right\} \\ \eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} & \longrightarrow h_2 = h_1 + (h_{2s} - h_1)/\eta_C \\ & = 239.19 + (275.40 - 239.19)/(0.85) \\ & = 281.79 \text{ kJ/kg} \\ P_3 = 0.8 \text{ MPa} & \left. \begin{aligned} h_3 &= h_f @ 0.8 \text{ MPa} = 95.48 \text{ kJ/kg} \\ \text{sat. liquid} & \end{aligned} \right\} \\ h_4 \cong h_3 &= 95.48 \text{ kJ/kg (throttling)} \end{aligned}$$

The quality of the refrigerant at the end of the throttling process is

$$x_4 = \left(\frac{h_4 - h_f}{h_{fg}} \right)_{@ 140 \text{ kPa}} = \frac{95.48 - 27.06}{212.13} = \mathbf{0.323}$$

(b) The COP of the refrigerator is determined from its definition,

$$\text{COP}_R = \frac{q_L}{w_{\text{in}}} = \frac{h_1 - h_4}{h_2 - h_1} = \frac{239.19 - 95.48}{281.79 - 239.19} = \mathbf{3.373}$$

(c) The power input to the compressor is determined from

$$\dot{W}_{\text{in}} = \frac{\dot{Q}_L}{\text{COP}_R} = \frac{5 \text{ kW}}{3.373} = \mathbf{1.48 \text{ kW}}$$

The exergy destruction associated with the compression process is determined from

$$\dot{X}_{\text{destroyed}} = T_0 \dot{S}_{\text{gen}} = T_0 \dot{m} \left(s_2 - s_1 + \frac{q_{\text{surr}}}{T_0} \right) = T_0 \dot{m} (s_2 - s_1)$$

where

$$\dot{m} = \frac{\dot{Q}_L}{q_L} = \frac{\dot{Q}_L}{h_1 - h_4} = \frac{5 \text{ kJ/s}}{(239.19 - 95.48) \text{ kJ/kg}} = 0.03479 \text{ kg/s}$$

$$\left. \begin{aligned} P_2 &= 0.8 \text{ MPa} \\ h_2 &= 281.79 \text{ kJ/kg} \end{aligned} \right\} s_2 = 0.96494 \text{ kJ/kg} \cdot \text{K}$$

Thus,

$$\dot{X}_{\text{destroyed}} = (298 \text{ K})(0.03479 \text{ kg/s})(0.96494 - 0.94467) \text{ kJ/kg} \cdot \text{K} = \mathbf{0.210 \text{ kW}}$$

11-17 A refrigerator with refrigerant-134a as the working fluid is considered. The rate of heat removal from the refrigerated space, the power input to the compressor, the isentropic efficiency of the compressor, and the COP of the refrigerator are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) From the refrigerant tables (Tables A-12 and A-13),

$$\left. \begin{array}{l} P_1 = 0.20 \text{ MPa} \\ T_1 = -5^\circ\text{C} \end{array} \right\} \begin{array}{l} h_1 = 248.82 \text{ kJ/kg} \\ s_1 = 0.95414 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_2 = 1.2 \text{ MPa} \\ T_2 = 70^\circ\text{C} \end{array} \right\} h_2 = 300.63 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_{2s} = 1.2 \text{ MPa} \\ s_{2s} = s_1 \end{array} \right\} h_{2s} = 287.23 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 1.15 \text{ MPa} \\ T_3 = 44^\circ\text{C} \end{array} \right\} h_3 = h_f @ 44^\circ\text{C} = 114.30 \text{ kJ/kg}$$

$$h_4 \cong h_3 = 114.30 \text{ kJ/kg (throttling)}$$

Then the rate of heat removal from the refrigerated space and the power input to the compressor are determined from

$$\dot{Q}_L = \dot{m}(h_1 - h_4) = (0.07 \text{ kg/s})(248.82 - 114.30) \text{ kJ/kg} = \mathbf{9.416 \text{ kW}}$$

and

$$\dot{W}_{\text{in}} = \dot{m}(h_2 - h_1) = (0.07 \text{ kg/s})(300.63 - 248.82) \text{ kJ/kg} = \mathbf{3.627 \text{ kW}}$$

(b) The isentropic efficiency of the compressor is determined from

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} = \frac{287.23 - 248.82}{300.63 - 248.82} = 0.7414 = \mathbf{74.1\%}$$

(c) The COP of the refrigerator is determined from its definition,

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} = \frac{9.416 \text{ kW}}{3.627 \text{ kW}} = \mathbf{2.60}$$

11-18 A commercial refrigerator with refrigerant-134a as the working fluid is considered. The quality of the refrigerant at the evaporator inlet, the refrigeration load, the COP of the refrigerator, and the theoretical maximum refrigeration load for the same power input to the compressor are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) From refrigerant-134a tables (Tables A-11 through A-13)

$$\left. \begin{array}{l} P_1 = 60 \text{ kPa} \\ T_1 = -34^\circ\text{C} \end{array} \right\} h_1 = 230.04 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_2 = 1200 \text{ kPa} \\ T_2 = 65^\circ\text{C} \end{array} \right\} h_2 = 295.18 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 1200 \text{ kPa} \\ T_3 = 42^\circ\text{C} \end{array} \right\} h_3 = 111.25 \text{ kJ/kg}$$

$$h_4 = h_3 = 111.25 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_4 = 60 \text{ kPa} \\ h_4 = 111.25 \text{ kJ/kg} \end{array} \right\} x_4 = \mathbf{0.4796}$$

Using saturated liquid enthalpy at the given temperature, for water we have (Table A-4)

$$h_{w1} = h_f @ 18^\circ\text{C} = 75.47 \text{ kJ/kg}$$

$$h_{w2} = h_f @ 26^\circ\text{C} = 108.94 \text{ kJ/kg}$$

(b) The mass flow rate of the refrigerant may be determined from an energy balance on the compressor

$$\dot{m}_R (h_2 - h_3) = \dot{m}_w (h_{w2} - h_{w1})$$

$$\dot{m}_R (295.18 - 111.25) \text{ kJ/kg} = (0.25 \text{ kg/s})(108.94 - 75.47) \text{ kJ/kg}$$

$$\longrightarrow \dot{m}_R = 0.04549 \text{ kg/s}$$

The waste heat transferred from the refrigerant, the compressor power input, and the refrigeration load are

$$\dot{Q}_H = \dot{m}_R (h_2 - h_3) = (0.04549 \text{ kg/s})(295.18 - 111.25) \text{ kJ/kg} = 8.367 \text{ kW}$$

$$\dot{W}_{\text{in}} = \dot{m}_R (h_2 - h_1) - \dot{Q}_{\text{in}} = (0.04549 \text{ kg/s})(295.18 - 230.04) \text{ kJ/kg} - 0.450 \text{ kW} = 2.513 \text{ kW}$$

$$\dot{Q}_L = \dot{Q}_H - \dot{W}_{\text{in}} - \dot{Q}_{\text{in}} = 8.367 - 2.513 - 0.450 = \mathbf{5.404 \text{ kW}}$$

(c) The COP of the refrigerator is determined from its definition

$$\text{COP} = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} = \frac{5.404}{2.513} = \mathbf{2.15}$$

(d) The reversible COP of the refrigerator for the same temperature limits is

$$\text{COP}_{\text{max}} = \frac{1}{T_H / T_L - 1} = \frac{1}{(18 + 273) / (-30 + 273) - 1} = 5.063$$

Then, the maximum refrigeration load becomes

$$\dot{Q}_{L,\text{max}} = \text{COP}_{\text{max}} \dot{W}_{\text{in}} = (5.063)(2.513 \text{ kW}) = \mathbf{12.72 \text{ kW}}$$

11-19 A refrigerator with refrigerant-134a as the working fluid is considered. The power input to the compressor, the rate of heat removal from the refrigerated space, and the pressure drop and the rate of heat gain in the line between the evaporator and the compressor are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) From the refrigerant tables (Tables A-12 and A-13),

$$\left. \begin{array}{l} P_1 = 100 \text{ kPa} \\ T_1 = -20^\circ\text{C} \end{array} \right\} \begin{array}{l} h_1 = 239.52 \text{ kJ/kg} \\ s_1 = 0.97215 \text{ kJ/kg} \cdot \text{K} \\ \nu_1 = 0.19841 \text{ m}^3/\text{kg} \end{array}$$

$$\left. \begin{array}{l} P_2 = 0.8 \text{ MPa} \\ s_{2s} = s_1 \end{array} \right\} \begin{array}{l} h_{2s} = 284.09 \text{ kJ/kg} \end{array}$$

$$\left. \begin{array}{l} P_3 = 0.75 \text{ MPa} \\ T_3 = 26^\circ\text{C} \end{array} \right\} \begin{array}{l} h_3 \cong h_f @ 26^\circ\text{C} = 87.83 \text{ kJ/kg} \end{array}$$

$$h_4 \cong h_3 = 87.83 \text{ kJ/kg} \text{ (throttling)}$$

$$\left. \begin{array}{l} T_5 = -26^\circ\text{C} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} P_5 = 0.10173 \text{ MPa} \\ h_5 = 234.70 \text{ kJ/kg} \end{array}$$

Then the mass flow rate of the refrigerant and the power input becomes

$$\dot{m} = \frac{\dot{V}_1}{\nu_1} = \frac{0.5/60 \text{ m}^3/\text{s}}{0.19841 \text{ m}^3/\text{kg}} = 0.04200 \text{ kg/s}$$

$$\dot{W}_{\text{in}} = \dot{m}(h_{2s} - h_1) / \eta_C = (0.04200 \text{ kg/s})[(284.09 - 239.52) \text{ kJ/kg}] / (0.78) = \mathbf{2.40 \text{ kW}}$$

(b) The rate of heat removal from the refrigerated space is

$$\dot{Q}_L = \dot{m}(h_5 - h_4) = (0.04200 \text{ kg/s})(234.70 - 87.83) \text{ kJ/kg} = \mathbf{6.17 \text{ kW}}$$

(c) The pressure drop and the heat gain in the line between the evaporator and the compressor are

$$\Delta P = P_5 - P_1 = 101.73 - 100 = \mathbf{1.73}$$

and

$$\dot{Q}_{\text{gain}} = \dot{m}(h_1 - h_5) = (0.04200 \text{ kg/s})(239.52 - 234.70) \text{ kJ/kg} = \mathbf{0.203 \text{ kW}}$$

11-20 Problem 11-19 is reconsidered. The effects of the compressor isentropic efficiency and the compressor inlet volume flow rate on the power input and the rate of refrigeration are to be investigated.

Analysis The problem is solved using EES, and the solution is given below.

11-21 A refrigerator uses refrigerant-134a as the working fluid and operates on the ideal vapor-compression refrigeration cycle except for the compression process. The mass flow rate of the refrigerant, the condenser pressure, and the COP of the refrigerator are to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis (a) (b) From the refrigerant-134a tables (Tables A-11 through A-13)

$$\left. \begin{array}{l} P_4 = 120 \text{ kPa} \\ x_4 = 0.34 \end{array} \right\} h_4 = 95.41 \text{ kJ/kg}$$

$$h_3 = h_4$$

$$\left. \begin{array}{l} h_3 = 95.41 \text{ kJ/kg} \\ x_3 = 0 \text{ (sat. liq.)} \end{array} \right\} P_3 = 799 \text{ kPa} \cong \mathbf{800 \text{ kPa}}$$

$$P_2 = P_3$$

$$\left. \begin{array}{l} P_2 = 799 \text{ kPa} \\ T_2 = 70^\circ\text{C} \end{array} \right\} h_2 = 306.92 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_1 = P_4 = 120 \text{ kPa} \\ x_1 = 1 \text{ (sat. vap.)} \end{array} \right\} h_1 = 236.99 \text{ kJ/kg}$$

The mass flow rate of the refrigerant is determined from

$$\dot{m} = \frac{\dot{W}_{in}}{h_2 - h_1} = \frac{0.45 \text{ kW}}{(306.92 - 236.99) \text{ kJ/kg}} = \mathbf{0.006435 \text{ kg/s}}$$

(c) The refrigeration load and the COP are

$$\begin{aligned} \dot{Q}_L &= \dot{m}(h_1 - h_4) \\ &= (0.06435 \text{ kg/s})(236.99 - 95.41) \text{ kJ/kg} \\ &= 0.9111 \text{ kW} \end{aligned}$$

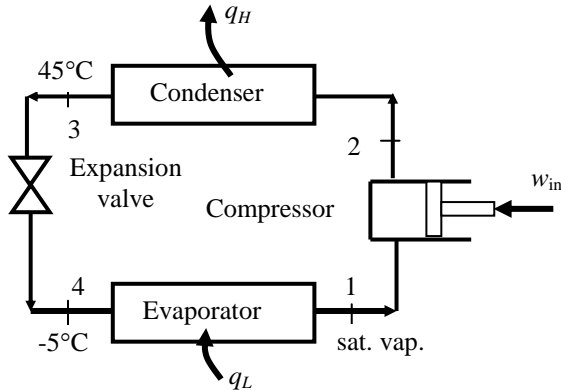

$$\text{COP} = \frac{\dot{Q}_L}{\dot{W}_{in}} = \frac{0.9111 \text{ kW}}{0.45 \text{ kW}} = \mathbf{2.03}$$

11-22 A vapor-compression refrigeration cycle with refrigerant-22 as the working fluid is considered. The hardware and the T - s diagram for this air conditioner are to be sketched. The heat absorbed by the refrigerant, the work input to the compressor and the heat rejected in the condenser are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) In this normal vapor-compression refrigeration cycle, the refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure.

(b) The properties as given in the problem statement are

$$h_4 = h_3 = h_f @ 45^\circ\text{C} = 101 \text{ kJ/kg}$$

$$h_1 = h_g @ -5^\circ\text{C} = 248.1 \text{ kJ/kg.}$$

The heat absorbed by the refrigerant in the evaporator is

$$q_L = h_1 - h_4 = 248.1 - 101 = \mathbf{147.1 \text{ kJ/kg}}$$

(c) The COP of the air conditioner is

$$\text{COP}_R = \text{SEER} \left(\frac{1 \text{ W}}{3.412 \text{ Btu/h}} \right) = \left(16 \frac{\text{Btu/h}}{\text{W}} \right) \left(\frac{1 \text{ W}}{3.412 \text{ Btu/h}} \right) = 4.689$$

The work input to the compressor is

$$\text{COP}_R = \frac{q_L}{w_{\text{in}}} \longrightarrow w_{\text{in}} = \frac{q_L}{\text{COP}_R} = \frac{147.1 \text{ kJ/kg}}{4.689} = \mathbf{31.4 \text{ kJ/kg}}$$

The enthalpy at the compressor exit is

$$w_{\text{in}} = h_2 - h_1 \longrightarrow h_2 = h_1 + w_{\text{in}} = 248.1 \text{ kJ/kg} + 31.4 \text{ kJ/kg} = 279.5 \text{ kJ/kg}$$

The heat rejected from the refrigerant in the condenser is then

$$q_H = h_2 - h_3 = 279.5 - 101 = \mathbf{178.5 \text{ kJ/kg}}$$

11-23 A vapor-compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The amount of cooling, the work input, and the COP are to be determined. Also, the same parameters are to be determined if the cycle operated on the ideal vapor-compression refrigeration cycle between the same temperature limits.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) The expansion process through the expansion valve is isenthalpic: $h_4 = h_3$. Then,

$$q_L = h_1 - h_4 = 402.49 - 243.19 = \mathbf{159.3 \text{ kJ/kg}}$$

$$q_H = h_2 - h_3 = 454.00 - 243.19 = 210.8 \text{ kJ/kg}$$

$$w_{\text{in}} = h_2 - h_1 = 454.00 - 402.49 = \mathbf{51.51 \text{ kJ/kg}}$$

$$\text{COP} = \frac{q_L}{w_{\text{in}}} = \frac{159.3 \text{ kJ/kg}}{51.51 \text{ kJ/kg}} = \mathbf{3.093}$$

(c) Ideal vapor-compression refrigeration cycle solution:

$$q_L = h_1 - h_4 = 399.04 - 249.80 = \mathbf{149.2 \text{ kJ/kg}}$$

$$q_H = h_2 - h_3 = 440.71 - 249.80 = 190.9 \text{ kJ/kg}$$

$$w_{\text{in}} = h_2 - h_1 = 440.71 - 399.04 = \mathbf{41.67 \text{ kJ/kg}}$$

$$\text{COP} = \frac{q_L}{w_{\text{in}}} = \frac{149.2 \text{ kJ/kg}}{41.67 \text{ kJ/kg}} = \mathbf{3.582}$$

Discussion In the ideal operation, the refrigeration load decreases by 6.3% and the work input by 19.1% while the COP increases by 15.8%.

Second-Law Analysis of Vapor-Compression Refrigeration Cycles

11-24C The second-law efficiency of a refrigerator operating on the vapor-compression refrigeration cycle is defined as

$$\eta_{\text{II,R}} = \frac{\dot{X}_{\dot{Q}_L}}{\dot{W}} = \frac{\dot{W}_{\text{min}}}{\dot{W}} = 1 - \frac{\dot{X}_{\text{dest,total}}}{\dot{W}}$$

where $\dot{X}_{\dot{Q}_L}$ is the exergy of the heat transferred from the low-temperature medium and it is expressed as

$$\dot{X}_{\dot{Q}_L} = -\dot{Q}_L \left(1 - \frac{T_0}{T_L} \right)$$

$\dot{X}_{\text{dest,total}}$ is the total exergy destruction in the cycle and \dot{W} is the actual power input to the cycle. The second-law efficiency can also be expressed as the ratio of the actual COP to the Carnot COP:

$$\eta_{\text{II,R}} = \frac{\text{COP}_{\text{R}}}{\text{COP}_{\text{Carnot}}}$$

11-25C The second-law efficiency of a heat pump operating on the a vapor-compression refrigeration cycle is defined as

$$\eta_{\text{II,HP}} = \frac{\dot{E}x_{\dot{Q}_H}}{\dot{W}} = \frac{\dot{W}_{\text{min}}}{\dot{W}} = 1 - \frac{\dot{E}x_{\text{dest,total}}}{\dot{W}}$$

Substituting

$$\dot{W} = \frac{\dot{Q}_H}{\text{COP}_{\text{HP}}} \quad \text{and} \quad \dot{E}x_{\dot{Q}_H} = \dot{Q}_H \left(1 - \frac{T_0}{T_H} \right)$$

into the second-law efficiency equation

$$\eta_{\text{II,HP}} = \frac{\dot{E}x_{\dot{Q}_H}}{\dot{W}} = \frac{\dot{Q}_H \left(1 - \frac{T_0}{T_H} \right)}{\frac{\dot{Q}_H}{\text{COP}_{\text{HP}}}} = \dot{Q}_H \left(1 - \frac{T_0}{T_H} \right) \frac{\text{COP}_{\text{HP}}}{\dot{Q}_H} = \frac{\text{COP}_{\text{HP}}}{\frac{T_H}{T_H - T_L}} = \frac{\text{COP}_{\text{HP}}}{\text{COP}_{\text{Carnot}}}$$

since $T_0 = T_L$.

11-26C In an isentropic compressor, $s_2 = s_1$ and $h_{2s} = h_2$. Applying these to the two the efficiency definitions, we obtain

$$\eta_{\text{s,Comp}} = \frac{w_{\text{isen}}}{w} = \frac{h_{2s} - h_1}{h_2 - h_1} = \frac{h_2 - h_1}{h_2 - h_1} = 1 = 100\%$$

$$\eta_{\text{II,Comp}} = \frac{w_{\text{rev}}}{w} = \frac{h_2 - h_1 - T_0(s_2 - s_1)}{h_2 - h_1} = \frac{h_2 - h_1}{h_2 - h_1} = 1 = 100\%$$

Thus, the isentropic efficiency and the second-law efficiency of an isentropic compressor are both 100%.

The second-law efficiency of a compressor is not necessarily equal to its isentropic efficiency. The two definitions are different as shown in the above equations. In the calculation of isentropic efficiency, the exit enthalpy is found at the hypothetical exit state (at the exit pressure and the inlet entropy) while the second-law efficiency involves the actual exit state. The two efficiencies are usually close but different. In the special case of an isentropic compressor, the two efficiencies become equal to each other as proven above.

11-27 A vapor-compression refrigeration system is used to keep a space at a low temperature. The power input, the COP and the second-law efficiency are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis The power input is

$$\dot{W}_{\text{in}} = \dot{Q}_H - \dot{Q}_L = 5500 - 3500 = 2000 \text{ kJ/h} = (2000 \text{ kJ/h}) \left(\frac{1 \text{ kW}}{3600 \text{ kJ/h}} \right) = \mathbf{0.5556 \text{ kW}}$$

The COP is

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} = \frac{(3500/3600) \text{ kW}}{0.5556 \text{ kW}} = \mathbf{1.75}$$

The COP of the Carnot cycle operating between the space and the ambient is

$$\text{COP}_{\text{Carnot}} = \frac{T_L}{T_H - T_L} = \frac{258 \text{ K}}{(298 - 258) \text{ K}} = 6.45$$

The second-law efficiency is then

$$\eta_{\text{II}} = \frac{\text{COP}_R}{\text{COP}_{\text{Carnot}}} = \frac{1.75}{6.45} = 0.271 = \mathbf{27.1\%}$$

11-28 A refrigerator is used to cool bananas at a specified rate. The rate of heat absorbed from the bananas, the COP, The minimum power input, the second-law efficiency and the exergy destruction are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) The rate of heat absorbed from the bananas is

$$\dot{Q}_L = \dot{m} c_p (T_1 - T_2) = (1140 \text{ kg/h})(3.35 \text{ kJ/kg} \cdot ^\circ\text{C})(28 - 12)^\circ\text{C} = \mathbf{61,100 \text{ kJ/h}}$$

The COP is

$$\text{COP} = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} = \frac{(61,100/3600) \text{ kW}}{8.6 \text{ kW}} = \frac{16.97 \text{ kW}}{8.6 \text{ kW}} = \mathbf{1.97}$$

(b) The minimum power input is equal to the exergy of the heat transferred from the low-temperature medium:

$$\dot{E}x_{\dot{Q}_L} = -\dot{Q}_L \left(1 - \frac{T_0}{T_L} \right) = -(16.97 \text{ kW}) \left(1 - \frac{28 + 273}{20 + 273} \right) = \mathbf{0.463 \text{ kW}}$$

where the dead state temperature is taken as the inlet temperature of the eggplants ($T_0 = 28^\circ\text{C}$) and the temperature of the low-temperature medium is taken as the average temperature of bananas $T = (12+28)/2 = 20^\circ\text{C}$.

(c) The second-law efficiency of the cycle is

$$\eta_{\text{II}} = \frac{\dot{E}x_{\dot{Q}_L}}{\dot{W}_{\text{in}}} = \frac{0.463}{8.6} = 0.0539 = \mathbf{5.39\%}$$

The exergy destruction is the difference between the exergy expended (power input) and the exergy recovered (the exergy of the heat transferred from the low-temperature medium):

$$\dot{E}x_{\text{dest}} = \dot{W}_{\text{in}} - \dot{E}x_{\dot{Q}_L} = 8.6 - 0.463 = \mathbf{8.14 \text{ kW}}$$

11-29 A vapor-compression refrigeration cycle is used to keep a space at a low temperature. The power input, the mass flow rate of water in the condenser, the second-law efficiency, and the exergy destruction are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) The power input is

$$\dot{W}_{\text{in}} = \frac{\dot{Q}_L}{\text{COP}} = \frac{(24,000 \text{ Btu/h}) \left(\frac{1 \text{ kW}}{3412 \text{ Btu/h}} \right)}{2.05} = \frac{7.034 \text{ kW}}{2.05} = \mathbf{3.431 \text{ kW}}$$

(b) From an energy balance on the cycle,

$$\dot{Q}_H = \dot{Q}_L + \dot{W}_{\text{in}} = 7.034 + 3.431 = 10.46 \text{ kW}$$

The mass flow rate of the water is then determined from

$$\dot{Q}_H = \dot{m} c_{pw} \Delta T_w \longrightarrow \dot{m} = \frac{\dot{Q}_H}{c_{pw} \Delta T_w} = \frac{10.46 \text{ kW}}{(4.18 \text{ kJ/kg} \cdot ^\circ\text{C})(12^\circ\text{C})} = \mathbf{0.2086 \text{ kg/s}}$$

(c) The exergy of the heat transferred from the low-temperature medium is

$$\dot{E}x_{\dot{Q}_L} = -\dot{Q}_L \left(1 - \frac{T_0}{T_L} \right) = -(7.034 \text{ kW}) \left(1 - \frac{20 + 273}{0 + 273} \right) = 0.5153 \text{ kW}$$

The second-law efficiency of the cycle is

$$\eta_{\text{II}} = \frac{\dot{E}x_{\dot{Q}_L}}{\dot{W}_{\text{in}}} = \frac{0.5153}{3.431} = 0.1502 = \mathbf{15.0\%}$$

The exergy destruction is the difference between the exergy supplied (power input) and the exergy recovered (the exergy of the heat transferred from the low-temperature medium):

$$\dot{E}x_{\text{dest}} = \dot{W}_{\text{in}} - \dot{E}x_{\dot{Q}_L} = 3.431 - 0.5153 = \mathbf{2.916 \text{ kW}}$$

Alternative Solution

The exergy efficiency can also be determined as follows:

$$\text{COP}_{\text{R,Carnot}} = \frac{T_L}{T_H - T_L} = \frac{0 + 273}{20 - 0} = 13.65$$

$$\eta_{\text{II}} = \frac{\text{COP}}{\text{COP}_{\text{R,Carnot}}} = \frac{2.05}{13.65} = 0.1502 = 15.0\%$$

The result is identical as expected.

11-30E A vapor-compression refrigeration cycle is used to keep a space at a low temperature. The mass flow rate of R-134a, the COP, the exergy destruction in each component, the second-law efficiency of the compressor, and the second-law efficiency and exergy destruction of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) The properties of R-134a are (Tables A-11E through A-13E)

$$\begin{aligned} P_1 = 20 \text{ psia} & \left\{ \begin{array}{l} h_1 = 102.74 \text{ Btu/lbm} \\ s_1 = 0.2257 \text{ Btu/lbm} \cdot \text{R} \end{array} \right. \\ x_1 = 1 & \\ P_2 = 140 \text{ psia} & \left\{ \begin{array}{l} h_2 = 131.37 \text{ Btu/lbm} \\ s_2 = 0.2444 \text{ Btu/lbm} \cdot \text{R} \end{array} \right. \\ T_2 = 160^\circ\text{F} & \\ P_3 = 140 \text{ psia} & \left\{ \begin{array}{l} h_3 = 45.31 \text{ Btu/lbm} \\ s_3 = 0.09215 \text{ Btu/lbm} \cdot \text{R} \end{array} \right. \\ x_3 = 0 & \\ h_4 = h_3 = 45.31 \text{ Btu/lbm} & \\ P_4 = 20 \text{ psia} & \left. \right\} s_4 = 0.1001 \text{ Btu/lbm} \cdot \text{R} \\ h_4 = 45.31 \text{ Btu/lbm} & \end{aligned}$$

The energy interactions in each component and the mass flow rate of R-134a are

$$w_{\text{in}} = h_2 - h_1 = 131.37 - 102.74 = 28.63 \text{ Btu/lbm}$$

$$q_H = h_2 - h_3 = 131.37 - 45.31 = 86.06 \text{ Btu/lbm}$$

$$q_L = q_H - w_{\text{in}} = 86.06 - 28.63 = 57.43 \text{ Btu/lbm}$$

$$\dot{m} = \frac{\dot{Q}_L}{q_L} = \frac{(45,000/3600) \text{ Btu/s}}{57.43 \text{ Btu/lbm}} = \mathbf{0.2177 \text{ lbm/s}}$$

The COP is

$$\text{COP} = \frac{q_L}{w_{\text{in}}} = \frac{57.43 \text{ Btu/lbm}}{28.63 \text{ Btu/lbm}} = \mathbf{2.006}$$

(b) The exergy destruction in each component of the cycle is determined as follows:

Compressor:

$$s_{\text{gen},1-2} = s_2 - s_1 = 0.2444 - 0.2257 = 0.01874 \text{ Btu/lbm} \cdot \text{R}$$

$$\dot{E}x_{\text{dest},1-2} = \dot{m}T_0 s_{\text{gen},1-2} = (0.2177 \text{ lbm/s})(540 \text{ R})(0.01874 \text{ Btu/lbm} \cdot \text{R}) = \mathbf{2.203 \text{ Btu/s}}$$

Condenser:

$$s_{\text{gen},2-3} = s_3 - s_2 + \frac{q_H}{T_H} = (0.09215 - 0.2444) \text{ Btu/lbm} \cdot \text{R} + \frac{86.06 \text{ Btu/lbm}}{540 \text{ R}} = 0.007073 \text{ Btu/lbm} \cdot \text{R}$$

$$\dot{E}x_{\text{dest},2-3} = \dot{m}T_0 s_{\text{gen},2-3} = (0.2177 \text{ lbm/s})(540 \text{ R})(0.007073 \text{ Btu/lbm} \cdot \text{R}) = \mathbf{0.8313 \text{ Btu/s}}$$

Expansion valve:

$$s_{\text{gen},3-4} = s_4 - s_3 = 0.1001 - 0.09215 = 0.007961 \text{ Btu/lbm} \cdot \text{R}$$

$$\dot{E}x_{\text{dest},3-4} = \dot{m}T_0 s_{\text{gen},3-4} = (0.2177 \text{ lbm/s})(540 \text{ R})(0.007961 \text{ Btu/lbm} \cdot \text{R}) = \mathbf{0.9358 \text{ Btu/s}}$$

Evaporator:

$$s_{\text{gen},4-1} = s_1 - s_4 - \frac{q_L}{T_L} = (0.2257 - 0.1001) \text{ Btu/lbm} \cdot \text{R} - \frac{57.43 \text{ Btu/lbm}}{470 \text{ R}} = 0.003400 \text{ Btu/lbm} \cdot \text{R}$$

$$\dot{E}x_{\text{dest},41} = \dot{m}T_0s_{\text{gen},41} = (0.2177 \text{ lbm/s})(540 \text{ R})(0.003400 \text{ Btu/lbm} \cdot \text{R}) = \mathbf{0.3996 \text{ Btu/s}}$$

The power input and the second-law efficiency of the compressor is determined from

$$\dot{W}_{\text{in}} = \dot{m}w_{\text{in}} = (0.2177 \text{ lbm/s})(28.63 \text{ Btu/lbm}) = 6.232 \text{ Btu/s}$$

$$\eta_{\text{II}} = 1 - \frac{\dot{E}x_{\text{dest},1-2}}{\dot{W}_{\text{in}}} = 1 - \frac{2.203 \text{ Btu/s}}{6.232 \text{ Btu/s}} = 0.6465 = \mathbf{64.7\%}$$

(c) The exergy of the heat transferred from the low-temperature medium is

$$\dot{E}x_{\dot{Q}_L} = -\dot{Q}_L \left(1 - \frac{T_0}{T_L} \right) = -(45000 / 3600 \text{ Btu/s}) \left(1 - \frac{540}{470} \right) = 1.862 \text{ Btu/s}$$

The second-law efficiency of the cycle is

$$\eta_{\text{II}} = \frac{\dot{E}x_{\dot{Q}_L}}{\dot{W}_{\text{in}}} = \frac{1.862 \text{ Btu/s}}{6.232 \text{ Btu/s}} = 0.2988 = \mathbf{29.9\%}$$

The total exergy destruction in the cycle is the difference between the exergy supplied (power input) and the exergy recovered (the exergy of the heat transferred from the low-temperature medium):

$$\dot{E}x_{\text{dest,total}} = \dot{W}_{\text{in}} - \dot{E}x_{\dot{Q}_L} = 6.232 - 1.862 = \mathbf{4.370 \text{ Btu/s}}$$

The total exergy destruction can also be determined by adding exergy destructions in each component:

$$\begin{aligned} \dot{E}x_{\text{dest,total}} &= \dot{E}x_{\text{dest},1-2} + \dot{E}x_{\text{dest},2-3} + \dot{E}x_{\text{dest},3-4} + \dot{E}x_{\text{dest},4-1} \\ &= 2.203 + 0.8313 + 0.9358 + 0.3996 \\ &= 4.370 \text{ Btu/s} \end{aligned}$$

The result is the same as expected.

11-31 A vapor-compression refrigeration cycle is used to keep a space at a low temperature. The mass flow rate of R-134a, the COP, The exergy destruction in each component and the exergy efficiency of the compressor, the second-law efficiency, and the exergy destruction are to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis (a) The properties of R-134a are (Tables A-11 through A-13)

$$\begin{aligned} P_2 = 1.2 \text{ MPa} & \left\{ \begin{array}{l} h_2 = 278.28 \text{ kJ/kg} \\ s_2 = 0.9268 \text{ kJ/kg} \cdot \text{K} \end{array} \right. \\ T_2 = 50^\circ\text{C} & \\ P_3 = 1.2 \text{ MPa} & \left\{ \begin{array}{l} h_3 = 117.79 \text{ kJ/kg} \\ s_3 = 0.4245 \text{ kJ/kg} \cdot \text{K} \end{array} \right. \\ x_3 = 0 & \end{aligned}$$

The rate of heat transferred to the water is the energy change of the water from inlet to exit

$$\dot{Q}_H = \dot{m}_w c_p (T_{w,2} - T_{w,1}) = (0.13 \text{ kg/s})(4.18 \text{ kJ/kg} \cdot ^\circ\text{C})(28 - 20)^\circ\text{C} = 4.347 \text{ kW}$$

The energy decrease of the refrigerant is equal to the energy increase of the water in the condenser. That is,

$$\dot{Q}_H = \dot{m}_R (h_2 - h_3) \longrightarrow \dot{m}_R = \frac{\dot{Q}_H}{h_2 - h_3} = \frac{4.347 \text{ kW}}{(278.28 - 117.79) \text{ kJ/kg}} = 0.02709 \text{ kg/s}$$

The refrigeration load is

$$\dot{Q}_L = \dot{Q}_H - \dot{W}_{\text{in}} = 4.347 - 1.9 = 2.447 \text{ kW} = (2.447 \text{ kW}) \left(\frac{3412 \text{ Btu/h}}{1 \text{ kW}} \right) = \mathbf{8350 \text{ Btu/h}}$$

The COP of the refrigerator is determined from its definition,

$$\text{COP} = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} = \frac{2.447 \text{ kW}}{1.9 \text{ kW}} = \mathbf{1.29}$$

(b) The COP of a reversible refrigerator operating between the same temperature limits is

$$\text{COP}_{\text{Carnot}} = \frac{T_L}{T_H - T_L} = \frac{-5 + 273}{(20 + 273) - (-5 + 273)} = 10.72$$

The minimum power input to the compressor for the same refrigeration load would be

$$\dot{W}_{\text{in,min}} = \frac{\dot{Q}_L}{\text{COP}_{\text{Carnot}}} = \frac{2.447 \text{ kW}}{10.72} = 0.2283 \text{ kW}$$

The second-law efficiency of the cycle is

$$\eta_{\text{II}} = \frac{\dot{W}_{\text{in,min}}}{\dot{W}_{\text{in}}} = \frac{0.2283}{1.9} = 0.120 = \mathbf{12.0\%}$$

The total exergy destruction in the cycle is the difference between the actual and the minimum power inputs:

$$\dot{E}x_{\text{dest,total}} = \dot{W}_{\text{in}} - \dot{W}_{\text{in,min}} = 1.9 - 0.2283 = \mathbf{1.67 \text{ kW}}$$

(c) The entropy generation in the condenser is

$$\begin{aligned} \dot{S}_{\text{gen,cond}} &= \dot{m}_w c_p \ln \left(\frac{T_{w,2}}{T_{w,1}} \right) + \dot{m}_R (s_3 - s_2) \\ &= (0.13 \text{ kg/s})(4.18 \text{ kJ/kg} \cdot ^\circ\text{C}) \ln \left(\frac{28 + 273}{20 + 273} \right) + (0.02709 \text{ kg/s})(0.4245 - 0.9268) \text{ kJ/kg} \cdot \text{K} \\ &= 0.001032 \text{ kW/K} \end{aligned}$$

The exergy destruction in the condenser is

$$\dot{E}x_{\text{dest,cond}} = T_0 \dot{S}_{\text{gen,cond}} = (293 \text{ K})(0.001032 \text{ kW/K}) = \mathbf{0.303 \text{ kW}}$$

11-32 An ideal vapor-compression refrigeration cycle is used to keep a space at a low temperature. The cooling load, the COP, the exergy destruction in each component, the total exergy destruction, and the second-law efficiency are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) The properties of R-134a are (Tables A-11 through A-13)

$$\left. \begin{aligned} T_1 &= -10^\circ\text{C} \\ x_1 &= 1 \end{aligned} \right\} \begin{aligned} h_1 &= 244.55 \text{ kJ/kg} \\ s_1 &= 0.9378 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

$$\left. \begin{aligned} P_2 &= P_{\text{sat}@57.9^\circ\text{C}} = 1600 \text{ kPa} \\ s_2 &= s_1 \end{aligned} \right\} \begin{aligned} h_2 &= 287.89 \text{ kJ/kg} \\ s_2 &= 0.9378 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

$$\left. \begin{aligned} P_3 &= 1600 \text{ kPa} \\ x_3 &= 0 \end{aligned} \right\} \begin{aligned} h_3 &= 135.96 \text{ kJ/kg} \\ s_3 &= 0.4792 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

$$h_4 = h_3 = 135.96 \text{ kJ/kg}$$

$$\left. \begin{aligned} T_4 &= -10^\circ\text{C} \\ h_4 &= 135.96 \text{ kJ/kg} \end{aligned} \right\} s_4 = 0.5252 \text{ kJ/kg}\cdot\text{K}$$

The energy interactions in the components and the COP are

$$q_L = h_1 - h_4 = 244.55 - 135.96 = \mathbf{108.6 \text{ kJ/kg}}$$

$$q_H = h_2 - h_3 = 287.89 - 135.96 = 151.9 \text{ kJ/kg}$$

$$w_{\text{in}} = h_2 - h_1 = 287.89 - 244.55 = 43.34 \text{ kJ/kg}$$

$$\text{COP} = \frac{q_L}{w_{\text{in}}} = \frac{108.6 \text{ kJ/kg}}{43.34 \text{ kJ/kg}} = \mathbf{2.506}$$

(b) The exergy destruction in each component of the cycle is determined as follows

Compressor:

$$s_{\text{gen},1-2} = s_2 - s_1 = 0$$

$$Ex_{\text{dest},1-2} = T_0 s_{\text{gen},1-2} = \mathbf{0}$$

Condenser:

$$s_{\text{gen},2-3} = s_3 - s_2 + \frac{q_H}{T_H} = (0.4792 - 0.9378) \text{ kJ/kg}\cdot\text{K} + \frac{151.9 \text{ kJ/kg}}{298 \text{ K}} = 0.05125 \text{ kJ/kg}\cdot\text{K}$$

$$Ex_{\text{dest},2-3} = T_0 s_{\text{gen},2-3} = (298 \text{ K})(0.05125 \text{ kJ/kg}\cdot\text{K}) = \mathbf{15.27 \text{ kJ/kg}}$$

Expansion valve:

$$s_{\text{gen},3-4} = s_4 - s_3 = 0.5252 - 0.4792 = 0.04595 \text{ kJ/kg}\cdot\text{K}$$

$$Ex_{\text{dest},3-4} = T_0 s_{\text{gen},3-4} = (298 \text{ K})(0.04595 \text{ kJ/kg}\cdot\text{K}) = \mathbf{13.69 \text{ kJ/kg}}$$

Evaporator:

$$s_{\text{gen},4-1} = s_1 - s_4 - \frac{q_L}{T_L} = (0.9378 - 0.5252) \text{ kJ/kg}\cdot\text{K} - \frac{108.6 \text{ kJ/kg}}{278 \text{ K}} = 0.02202 \text{ kJ/kg}\cdot\text{K}$$

$$Ex_{\text{dest},4-1} = T_0 s_{\text{gen},4-1} = (298 \text{ K})(0.02202 \text{ kJ/kg}\cdot\text{K}) = \mathbf{6.56 \text{ kJ/kg}}$$

The total exergy destruction can be determined by adding exergy destructions in each component:

$$\begin{aligned}\dot{E}x_{\text{dest,total}} &= \dot{E}x_{\text{dest},1,2} + \dot{E}x_{\text{dest},2,3} + \dot{E}x_{\text{dest},3,4} + \dot{E}x_{\text{dest},4,1} \\ &= 0 + 15.27 + 13.69 + 6.56 \\ &= \mathbf{35.52 \text{ kJ/kg}}\end{aligned}$$

(c) The exergy of the heat transferred from the low-temperature medium is

$$Ex_{q_L} = -q_L \left(1 - \frac{T_0}{T_L} \right) = -(108.6 \text{ kJ/kg}) \left(1 - \frac{298}{278} \right) = 7.813 \text{ kJ/kg}$$

The second-law efficiency of the cycle is

$$\eta_{\text{II}} = \frac{Ex_{q_L}}{w_{\text{in}}} = \frac{7.813}{43.34} = 0.180 = \mathbf{18.0\%}$$

The total exergy destruction in the cycle can also be determined from

$$E\dot{x}_{\text{dest,total}} = w_{\text{in}} - Ex_{q_L} = 43.34 - 7.813 = 35.53 \text{ kJ/kg}$$

The result is practically identical as expected.

The second-law efficiency of the compressor is determined from

$$\eta_{\text{II,Comp}} = \frac{\dot{X}_{\text{recovered}}}{\dot{X}_{\text{expended}}} = \frac{\dot{W}_{\text{rev}}}{\dot{W}_{\text{act,in}}} = \frac{\dot{m}[h_2 - h_1 - T_0(s_2 - s_1)]}{\dot{m}(h_2 - h_1)}$$

since the compression through the compressor is isentropic ($s_2 = s_1$), the second-law efficiency is

$$\eta_{\text{II,Comp}} = 1 = \mathbf{100\%}$$

The second-law efficiency of the evaporator is determined from

$$\eta_{\text{II,Evap}} = \frac{\dot{X}_{\text{recovered}}}{\dot{X}_{\text{expended}}} = \frac{\dot{Q}_L(T_0 - T_L)/T_L}{\dot{m}[h_4 - h_1 - T_0(s_4 - s_1)]} = 1 - \frac{\dot{X}_{\text{dest},4,1}}{\dot{X}_4 - \dot{X}_1}$$

where

$$\begin{aligned}x_4 - x_1 &= h_4 - h_1 - T_0(s_4 - s_1) \\ &= (135.96 - 244.55) \text{ kJ/kg} - (298 \text{ K})(0.5252 - 0.9378) \text{ kJ/kg} \cdot \text{K} \\ &= 14.37 \text{ kJ/kg}\end{aligned}$$

Substituting,

$$\eta_{\text{II,Evap}} = 1 - \frac{x_{\text{dest},4,1}}{x_4 - x_1} = 1 - \frac{6.56 \text{ kJ/kg}}{14.37 \text{ kJ/kg}} = 0.544 = \mathbf{54.4\%}$$

11-33 An ideal vapor-compression refrigeration cycle uses ammonia as the refrigerant. The volume flow rate at the compressor inlet, the power input, the COP, the second-law efficiency and the total exergy destruction are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) The properties of ammonia are given in problem statement. An energy balance on the condenser gives

$$q_H = h_1 - h_4 = 1439.3 - 437.4 = 1361 \text{ kJ/kg}$$

$$\dot{m} = \frac{\dot{Q}_H}{q_H} = \frac{18 \text{ kW}}{1361 \text{ kJ/kg}} = 0.01323 \text{ kg/s}$$

The volume flow rate is determined from

$$\begin{aligned} \dot{V}_1 &= \dot{m}v_1 = (0.01323 \text{ kg/s})(0.5946 \text{ m}^3/\text{kg}) \\ &= 0.007865 \text{ m}^3/\text{s} = \mathbf{7.87 \text{ L/s}} \end{aligned}$$

(b) The power input and the COP are

$$\dot{W}_{\text{in}} = \dot{m}(h_2 - h_1) = (0.01323 \text{ kg/s})(1798.3 - 1439.3) \text{ kJ/kg} = \mathbf{4.75 \text{ kW}}$$

$$\dot{Q}_L = \dot{m}(h_1 - h_4) = (0.01323 \text{ kg/s})(1439.3 - 437.4) \text{ kJ/kg} = 13.25 \text{ kW}$$

$$\text{COP} = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} = \frac{13.25 \text{ kW}}{4.75 \text{ kW}} = \mathbf{2.79}$$

(c) The exergy of the heat transferred from the low-temperature medium is

$$\dot{E}x_{\dot{Q}_L} = -\dot{Q}_L \left(1 - \frac{T_0}{T_L} \right) = -(13.25 \text{ kW}) \left(1 - \frac{300}{264} \right) = 1.81 \text{ kW}$$

The second-law efficiency of the cycle is

$$\eta_{\text{II}} = \frac{\dot{E}x_{\dot{Q}_L}}{\dot{W}_{\text{in}}} = \frac{1.81}{4.75} = 0.381 = \mathbf{38.1\%}$$

The total exergy destruction in the cycle is the difference between the exergy supplied (power input) and the exergy recovered (the exergy of the heat transferred from the low-temperature medium):

$$\dot{E}x_{\text{dest,total}} = \dot{W}_{\text{in}} - \dot{E}x_{\dot{Q}_L} = 4.75 - 1.81 = \mathbf{2.94 \text{ kW}}$$

11-34 Prob. 11-33 is reconsidered. Using EES software, the problem is to be repeated ammonia, R-134a and R-22 is used as a refrigerant and the effects of evaporator and condenser pressures on the COP, the second-law efficiency and the total exergy destruction are to be investigated.

Analysis The equations as written in EES are

Selecting the Right Refrigerant

11-35C The desirable characteristics of a refrigerant are to have an evaporator pressure which is above the atmospheric pressure, and a condenser pressure which corresponds to a saturation temperature above the temperature of the cooling medium. Other desirable characteristics of a refrigerant include being nontoxic, noncorrosive, nonflammable, chemically stable, having a high enthalpy of vaporization (minimizes the mass flow rate) and, of course, being available at low cost.

11-36C The minimum pressure that the refrigerant needs to be compressed to is the saturation pressure of the refrigerant at 30°C, which is **0.771 MPa**. At lower pressures, the refrigerant will have to condense at temperatures lower than the temperature of the surroundings, which cannot happen.

11-37C Allowing a temperature difference of 10°C for effective heat transfer, the evaporation temperature of the refrigerant should be -20°C. The saturation pressure corresponding to -20°C is 0.133 MPa. Therefore, the recommended pressure would be 0.12 MPa.

11-38 A refrigerator that operates on the ideal vapor-compression cycle with refrigerant-134a is considered. Reasonable pressures for the evaporator and the condenser are to be selected.

Assumptions **1** Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis Allowing a temperature difference of 10°C for effective heat transfer, the evaporation and condensation temperatures of the refrigerant should be -20°C and 35°C, respectively. The saturation pressures corresponding to these temperatures are 0.133 MPa and 0.888 MPa. Therefore, the recommended evaporator and condenser pressures are **0.133 MPa** and **0.888 MPa**, respectively.

11-39 A heat pump that operates on the ideal vapor-compression cycle with refrigerant-134a is considered. Reasonable pressures for the evaporator and the condenser are to be selected.

Assumptions **1** Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis Allowing a temperature difference of 10°C for effective heat transfer, the evaporation and condensation temperatures of the refrigerant should be 4°C and 36°C, respectively. The saturation pressures corresponding to these temperatures are 338 kPa and 912 kPa. Therefore, the recommended evaporator and condenser pressures are **338 kPa** and **912 kPa**, respectively.

Heat Pump Systems

11-40C A heat pump system is more cost effective in Miami because of the low heating loads and high cooling loads at that location.

11-41C A water-source heat pump extracts heat from water instead of air. Water-source heat pumps have higher COPs than the air-source systems because the temperature of water is higher than the temperature of air in winter.

11-42 A heat pump that operates on the ideal vapor-compression cycle with refrigerant-134a is considered. The power input to the heat pump is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis In an ideal vapor-compression refrigeration cycle, the compression process is isentropic, the refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure. From the refrigerant tables (Tables A-12 and A-13),

$$P_1 = 320 \text{ kPa} \left\{ \begin{array}{l} h_1 = h_g @ 320 \text{ kPa} = 251.93 \text{ kJ/kg} \\ \text{sat. vapor} \quad \left. \begin{array}{l} s_1 = s_g @ 320 \text{ kPa} = 0.93026 \text{ kJ/kg} \cdot \text{K} \end{array} \right\} \end{array} \right.$$

$$P_2 = 1.4 \text{ MPa} \left\{ \begin{array}{l} h_2 = 282.60 \text{ kJ/kg} \\ s_2 = s_1 \end{array} \right.$$

$$P_3 = 1.4 \text{ MPa} \left\{ \begin{array}{l} h_3 = h_f @ 1.4 \text{ MPa} = 127.25 \text{ kJ/kg} \\ \text{sat. liquid} \end{array} \right.$$

$$h_4 \cong h_3 = 127.25 \text{ kJ/kg} \quad (\text{throttling})$$

The heating load of this heat pump is determined from

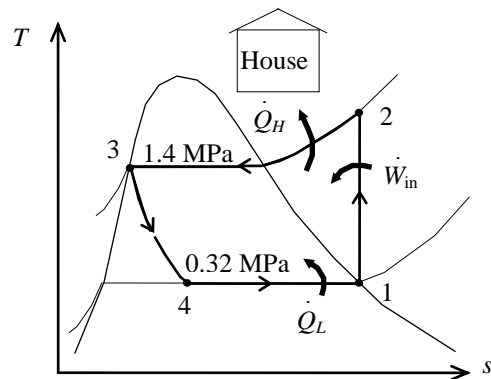

$$\begin{aligned} \dot{Q}_H &= [\dot{m}c(T_2 - T_1)]_{\text{water}} \\ &= (0.12 \text{ kg/s})(4.18 \text{ kJ/kg} \cdot ^\circ\text{C})(45 - 15)^\circ\text{C} \\ &= 15.05 \text{ kW} \end{aligned}$$

and

$$\dot{m}_R = \frac{\dot{Q}_H}{q_H} = \frac{\dot{Q}_H}{h_2 - h_3} = \frac{15.05 \text{ kJ/s}}{(282.60 - 127.25) \text{ kJ/kg}} = 0.09686 \text{ kg/s}$$

Then,

$$\dot{W}_{\text{in}} = \dot{m}_R(h_2 - h_1) = (0.09686 \text{ kg/s})(282.60 - 251.93) \text{ kJ/kg} = \mathbf{2.97 \text{ kW}}$$

11-43 A geothermal heat pump is considered. The degrees of subcooling done on the refrigerant in the condenser, the mass flow rate of the refrigerant, the heating load, the COP of the heat pump, the minimum power input are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) From the refrigerant-134a tables (Tables A-11 through A-13)

$$\begin{aligned} T_4 = 20^\circ\text{C} \left. \begin{array}{l} P_4 = 572.1 \text{ kPa} \\ x_4 = 0.23 \end{array} \right\} h_4 = 121.25 \text{ kJ/kg} \\ h_3 = h_4 = 121.25 \text{ kJ/kg} \\ P_1 = 572.1 \text{ kPa} \left. \begin{array}{l} h_1 = 261.64 \text{ kJ/kg} \\ x_1 = 1 \text{ (sat. vap.)} \end{array} \right\} s_1 = 0.9225 \text{ kJ/kg} \\ P_2 = 1400 \text{ kPa} \left. \begin{array}{l} h_2 = 280.05 \text{ kJ/kg} \\ s_2 = s_1 \end{array} \right\} \end{aligned}$$

From the steam tables (Table A-4)

$$\begin{aligned} h_{w1} &= h_f @ 50^\circ\text{C} = 209.34 \text{ kJ/kg} \\ h_{w2} &= h_f @ 40^\circ\text{C} = 167.53 \text{ kJ/kg} \end{aligned}$$

The saturation temperature at the condenser pressure of 1400 kPa and the actual temperature at the condenser outlet are

$$\begin{aligned} T_{\text{sat @ 1400 kPa}} &= 52.40^\circ\text{C} \\ P_3 = 1400 \text{ kPa} \left. \begin{array}{l} h_3 = 121.25 \text{ kJ/kg} \end{array} \right\} T_3 &= 48.58^\circ\text{C} \text{ (from EES)} \end{aligned}$$

Then, the degrees of subcooling is

$$\Delta T_{\text{subcool}} = T_{\text{sat}} - T_3 = 52.40 - 48.58 = \mathbf{3.82^\circ\text{C}}$$

(b) The rate of heat absorbed from the geothermal water in the evaporator is

$$\dot{Q}_L = \dot{m}_w (h_{w1} - h_{w2}) = (0.065 \text{ kg/s})(209.34 - 167.53) \text{ kJ/kg} = 2.718 \text{ kW}$$

This heat is absorbed by the refrigerant in the evaporator

$$\dot{m}_R = \frac{\dot{Q}_L}{h_1 - h_4} = \frac{2.718 \text{ kW}}{(261.64 - 121.25) \text{ kJ/kg}} = \mathbf{0.01936 \text{ kg/s}}$$

(c) The power input to the compressor, the heating load and the COP are

$$\dot{W}_{\text{in}} = \dot{m}_R (h_2 - h_1) + \dot{Q}_{\text{out}} = (0.01936 \text{ kg/s})(280.05 - 261.64) \text{ kJ/kg} = 0.6563 \text{ kW}$$

$$\dot{Q}_H = \dot{m}_R (h_2 - h_3) = (0.01936 \text{ kg/s})(280.05 - 121.25) \text{ kJ/kg} = \mathbf{3.074 \text{ kW}}$$

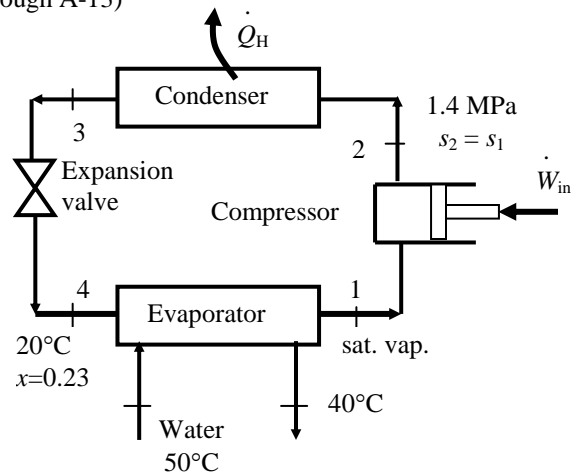

$$\text{COP} = \frac{\dot{Q}_H}{\dot{W}_{\text{in}}} = \frac{3.074 \text{ kW}}{0.6563 \text{ kW}} = \mathbf{4.68}$$

(d) The reversible COP of the cycle is

$$\text{COP}_{\text{rev}} = \frac{1}{1 - T_L / T_H} = \frac{1}{1 - (25 + 273) / (50 + 273)} = 12.92$$

The corresponding minimum power input is

$$\dot{W}_{\text{in, min}} = \frac{\dot{Q}_H}{\text{COP}_{\text{rev}}} = \frac{3.074 \text{ kW}}{12.92} = \mathbf{0.238 \text{ kW}}$$

11-44 An actual heat pump cycle with R-134a as the refrigerant is considered. The isentropic efficiency of the compressor, the rate of heat supplied to the heated room, the COP of the heat pump, and the COP and the rate of heat supplied to the heated room if this heat pump operated on the ideal vapor-compression cycle between the same pressure limits are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) The properties of refrigerant-134a are (Tables A-11 through A-13)

$$\left. \begin{aligned} P_2 &= 800 \text{ kPa} \\ T_2 &= 50^\circ\text{C} \end{aligned} \right\} h_2 = 286.71 \text{ kJ/kg}$$

$$T_3 = T_{\text{sat}@750\text{kPa}} = 29.06^\circ\text{C}$$

$$\left. \begin{aligned} P_3 &= 750 \text{ kPa} \\ T_3 &= (29.06 - 3)^\circ\text{C} \end{aligned} \right\} h_3 = 87.93 \text{ kJ/kg}$$

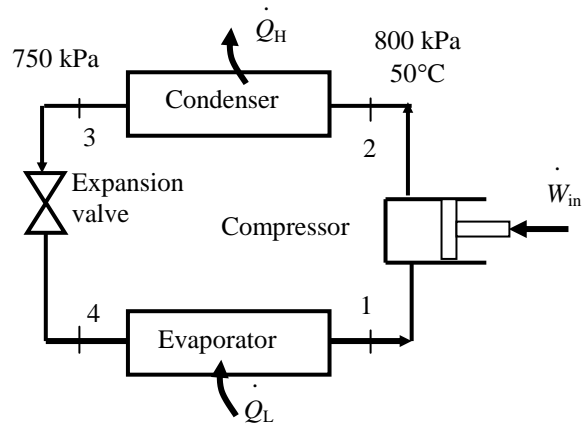

$$h_4 = h_3 = 87.93 \text{ kJ/kg}$$

$$T_{\text{sat}@200\text{kPa}} = -10.09^\circ\text{C}$$

$$\left. \begin{aligned} P_1 &= 200 \text{ kPa} \\ T_1 &= (-10.09 + 4)^\circ\text{C} \end{aligned} \right\} h_1 = 247.88 \text{ kJ/kg}$$

$$s_1 = 0.9507 \text{ kJ/kg}\cdot\text{K}$$

$$\left. \begin{aligned} P_2 &= 800 \text{ kPa} \\ s_2 &= s_1 \end{aligned} \right\} h_{2s} = 277.28$$

The isentropic efficiency of the compressor is

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} = \frac{277.28 - 247.88}{286.71 - 247.88} = \mathbf{0.757}$$

(b) The rate of heat supplied to the room is

$$\dot{Q}_H = \dot{m}(h_2 - h_3) = (0.022 \text{ kg/s})(286.71 - 87.93) \text{ kJ/kg} = \mathbf{4.373 \text{ kW}}$$

(c) The power input and the COP are

$$\dot{W}_{\text{in}} = \dot{m}(h_2 - h_1) = (0.022 \text{ kg/s})(286.71 - 247.88) \text{ kJ/kg} = 0.8542 \text{ kW}$$

$$\text{COP} = \frac{\dot{Q}_H}{\dot{W}_{\text{in}}} = \frac{4.373}{0.8542} = \mathbf{5.12}$$

(d) The ideal vapor-compression cycle analysis of the cycle is as follows:

$$h_1 = h_g@200\text{kPa} = 244.50 \text{ kJ/kg}$$

$$s_1 = s_g@200\text{kPa} = 0.9379 \text{ kJ/kg}\cdot\text{K}$$

$$\left. \begin{aligned} P_2 &= 800 \text{ kPa} \\ s_2 &= s_1 \end{aligned} \right\} h_2 = 273.29 \text{ kJ/kg}$$

$$h_3 = h_f@800\text{kPa} = 95.48 \text{ kJ/kg}$$

$$h_4 = h_3$$

$$\text{COP} = \frac{h_2 - h_3}{h_2 - h_1} = \frac{273.29 - 95.48}{273.29 - 244.50} = \mathbf{6.18}$$

$$\dot{Q}_H = \dot{m}(h_2 - h_3) = (0.022 \text{ kg/s})(273.29 - 95.48) \text{ kJ/kg} = \mathbf{3.91 \text{ kW}}$$

11-45E A heat pump that operates on the ideal vapor-compression cycle with refrigerant-134a is considered. The power input to the heat pump and the electric power saved by using a heat pump instead of a resistance heater are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis In an ideal vapor-compression refrigeration cycle, the compression process is isentropic, the refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure. From the refrigerant tables (Tables A-12E and A-13E),

$$P_1 = 50 \text{ psia} \left\{ \begin{array}{l} h_1 = h_g @ 50 \text{ psia} = 108.83 \text{ Btu/lbm} \\ \text{sat. vapor} \quad \left. \begin{array}{l} s_1 = s_g @ 50 \text{ psia} = 0.22192 \text{ Btu/lbm} \cdot \text{R} \end{array} \right\} \end{array} \right.$$

$$P_2 = 120 \text{ psia} \left\{ \begin{array}{l} h_2 = 116.64 \text{ Btu/lbm} \\ s_2 = s_1 \end{array} \right.$$

$$P_3 = 120 \text{ psia} \left\{ \begin{array}{l} h_3 = h_f @ 120 \text{ psia} = 41.79 \text{ Btu/lbm} \\ \text{sat. liquid} \end{array} \right.$$

$$h_4 \cong h_3 = 41.79 \text{ Btu/lbm (throttling)}$$

The mass flow rate of the refrigerant and the power input to the compressor are determined from

$$\dot{m} = \frac{\dot{Q}_H}{q_H} = \frac{\dot{Q}_H}{h_2 - h_3} = \frac{60,000/3600 \text{ Btu/s}}{(116.64 - 41.79) \text{ Btu/lbm}} = 0.2227 \text{ lbm/s}$$

and

$$\begin{aligned} \dot{W}_{\text{in}} &= \dot{m}(h_2 - h_1) = (0.2227 \text{ kg/s})(116.64 - 108.83) \text{ Btu/lbm} \\ &= 1.739 \text{ Btu/s} = \mathbf{2.46 \text{ hp}} \text{ since } 1 \text{ hp} = 0.7068 \text{ Btu/s} \end{aligned}$$

The electrical power required without the heat pump is

$$\dot{W}_e = \dot{Q}_H = (60,000/3600 \text{ Btu/s}) \left(\frac{1 \text{ hp}}{0.7068 \text{ Btu/s}} \right) = 23.58 \text{ hp}$$

Thus,

$$\begin{aligned} \dot{W}_{\text{saved}} &= \dot{W}_e - \dot{W}_{\text{in}} = 23.58 - 2.46 \\ &= \mathbf{21.1 \text{ hp}} = 15.75 \text{ kW} \text{ since } 1 \text{ hp} = 0.7457 \text{ kW} \end{aligned}$$

11-46 A heat pump with refrigerant-134a as the working fluid heats a house by using underground water as the heat source. The power input to the heat pump, the rate of heat absorption from the water, and the increase in electric power input if an electric resistance heater is used instead of a heat pump are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) From the refrigerant tables (Tables A-12 and A-13),

$$\left. \begin{array}{l} P_1 = 280 \text{ kPa} \\ T_1 = 0^\circ\text{C} \end{array} \right\} h_1 = 250.85 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_2 = 1.0 \text{ MPa} \\ T_2 = 60^\circ\text{C} \end{array} \right\} h_2 = 293.40 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 1.0 \text{ MPa} \\ T_3 = 30^\circ\text{C} \end{array} \right\} h_3 \cong h_f @ 30^\circ\text{C} = 93.58 \text{ kJ/kg}$$

$$h_4 \cong h_3 = 93.58 \text{ kJ/kg (throttling)}$$

The mass flow rate of the refrigerant is

$$\dot{m}_R = \frac{\dot{Q}_H}{q_H} = \frac{\dot{Q}_H}{h_2 - h_3} = \frac{60,000/3,600 \text{ kJ/s}}{(293.40 - 93.58) \text{ kJ/kg}} = 0.08341 \text{ kg/s}$$

Then the power input to the compressor becomes

$$\dot{W}_{\text{in}} = \dot{m}(h_2 - h_1) = (0.08341 \text{ kg/s})(293.40 - 250.85) \text{ kJ/kg} = \mathbf{3.55 \text{ kW}}$$

(b) The rate of heat absorption from the water is

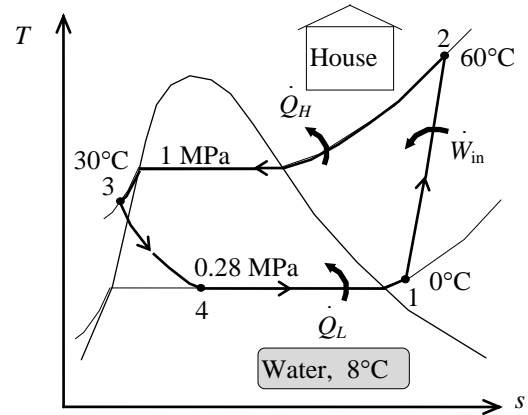

$$\dot{Q}_L = \dot{m}(h_1 - h_4) = (0.08341 \text{ kg/s})(250.85 - 93.58) \text{ kJ/kg} = \mathbf{13.12 \text{ kW}}$$

(c) The electrical power required without the heat pump is

$$\dot{W}_e = \dot{Q}_H = 60,000/3600 \text{ kJ/s} = 16.67 \text{ kW}$$

Thus,

$$\dot{W}_{\text{increase}} = \dot{W}_e - \dot{W}_{\text{in}} = 16.67 - 3.55 = \mathbf{13.12 \text{ kW}}$$

11-47 Problem 11-46 is reconsidered. The effect of the compressor isentropic efficiency on the power input to the compressor and the electric power saved by using a heat pump rather than electric resistance heating is to be investigated.

Analysis The problem is solved using EES, and the solution is given below.

Innovative Refrigeration Systems

11-48C Cascade refrigeration systems have higher COPs than the ordinary refrigeration systems operating between the same pressure limits.

11-49C The saturation pressure of refrigerant-134a at -32°C is 77 kPa, which is below the atmospheric pressure. In reality a pressure below this value should be used. Therefore, a cascade refrigeration system with a different refrigerant at the bottoming cycle is recommended in this case.

11-50C We would favor the two-stage compression refrigeration system with a flash chamber since it is simpler, cheaper, and has better heat transfer characteristics.

11-51C Yes, by expanding the refrigerant in stages in several throttling devices.

11-52C To take advantage of the cooling effect by throttling from high pressures to low pressures.

11-53  A two-stage compression refrigeration system with refrigerant-134a as the working fluid is considered. The fraction of the refrigerant that evaporates as it is throttled to the flash chamber, the rate of heat removed from the refrigerated space, and the COP are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible. **3** The flash chamber is adiabatic.

Analysis (a) The enthalpies of the refrigerant at several states are determined from the refrigerant tables (Tables A-11, A-12, and A-13) to be

$$h_1 = 234.46 \text{ kJ/kg}, \quad h_2 = 262.70 \text{ kJ/kg}$$

$$h_3 = 255.61 \text{ kJ/kg},$$

$$h_5 = 127.25 \text{ kJ/kg}, \quad h_6 = 127.25 \text{ kJ/kg}$$

$$h_7 = 63.92 \text{ kJ/kg}, \quad h_8 = 63.92 \text{ kJ/kg}$$

The fraction of the refrigerant that evaporates as it is throttled to the flash chamber is simply the quality at state 6,

$$x_6 = \frac{h_6 - h_f}{h_{fg}} = \frac{127.25 - 63.92}{191.68} = \mathbf{0.3304}$$

(b) The enthalpy at state 9 is determined from an energy balance on the mixing chamber:

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\phi^0(\text{steady})}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_e h_e = \sum \dot{m}_i h_i$$

$$(1)h_9 = x_6 h_3 + (1 - x_6)h_2$$

$$h_9 = (0.3304)(255.61) + (1 - 0.3304)(262.70) = 260.35 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_9 = 0.4 \text{ MPa} \\ h_9 = 260.35 \text{ kJ/kg} \end{array} \right\} s_9 = 0.9438 \text{ kJ/kg} \cdot \text{K}$$

Also,

$$\left. \begin{array}{l} P_4 = 1.4 \text{ MPa} \\ s_4 = s_9 = 0.9438 \text{ kJ/kg} \cdot \text{K} \end{array} \right\} h_4 = 287.10 \text{ kJ/kg}$$

Then the rate of heat removed from the refrigerated space and the compressor work input per unit mass of refrigerant flowing through the condenser are

$$\dot{m}_B = (1 - x_6)\dot{m}_A = (1 - 0.3304)(0.25 \text{ kg/s}) = 0.1674 \text{ kg/s}$$

$$\dot{Q}_L = \dot{m}_B (h_1 - h_8) = (0.1674 \text{ kg/s})(234.46 - 63.92) \text{ kJ/kg} = \mathbf{28.55 \text{ kW}}$$

$$\begin{aligned} \dot{W}_{\text{in}} &= \dot{W}_{\text{comp I, in}} + \dot{W}_{\text{comp II, in}} = \dot{m}_A (h_4 - h_9) + \dot{m}_B (h_2 - h_1) \\ &= (0.25 \text{ kg/s})(287.10 - 260.35) \text{ kJ/kg} + (0.1674 \text{ kg/s})(262.70 - 234.46) \text{ kJ/kg} \\ &= 11.41 \text{ kW} \end{aligned}$$

(c) The coefficient of performance is determined from

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{\text{net, in}}} = \frac{28.55 \text{ kW}}{11.41 \text{ kW}} = \mathbf{2.50}$$

11-54 A two-stage compression refrigeration system with refrigerant-134a as the working fluid is considered. The fraction of the refrigerant that evaporates as it is throttled to the flash chamber, the rate of heat removed from the refrigerated space, and the COP are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible. 3 The flash chamber is adiabatic.

Analysis (a) The enthalpies of the refrigerant at several states are determined from the refrigerant tables (Tables A-11, A-12, and A-13) to be

$$h_1 = 234.46 \text{ kJ/kg}, \quad h_2 = 271.42 \text{ kJ/kg}$$

$$h_3 = 262.46 \text{ kJ/kg},$$

$$h_5 = 127.25 \text{ kJ/kg}, \quad h_6 = 127.25 \text{ kJ/kg}$$

$$h_7 = 81.50 \text{ kJ/kg}, \quad h_8 = 81.50 \text{ kJ/kg}$$

The fraction of the refrigerant that evaporates as it is throttled to the flash chamber is simply the quality at state 6,

$$x_6 = \frac{h_6 - h_f}{h_{fg}} = \frac{127.25 - 81.50}{180.95} = \mathbf{0.2528}$$

(b) The enthalpy at state 9 is determined from an energy balance on the mixing chamber:

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \overset{\phi^0(\text{steady})}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_e h_e = \sum \dot{m}_i h_i$$

$$(1)\dot{h}_9 = x_6 \dot{h}_3 + (1 - x_6) \dot{h}_2$$

$$h_9 = (0.2528)(262.46) + (1 - 0.2528)(271.42) = 269.15 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_9 = 0.6 \text{ MPa} \\ h_9 = 269.15 \text{ kJ/kg} \end{array} \right\} s_9 = 0.9444 \text{ kJ/kg} \cdot \text{K}$$

Also,

$$\left. \begin{array}{l} P_4 = 1.4 \text{ MPa} \\ s_4 = s_9 = 0.9444 \text{ kJ/kg} \cdot \text{K} \end{array} \right\} h_4 = 287.31 \text{ kJ/kg}$$

Then the rate of heat removed from the refrigerated space and the compressor work input per unit mass of refrigerant flowing through the condenser are

$$\dot{m}_B = (1 - x_6) \dot{m}_A = (1 - 0.2528)(0.25 \text{ kg/s}) = 0.1868 \text{ kg/s}$$

$$\dot{Q}_L = \dot{m}_B (h_1 - h_8) = (0.1868 \text{ kg/s})(234.46 - 81.50) \text{ kJ/kg} = \mathbf{28.57 \text{ kW}}$$

$$\begin{aligned} \dot{W}_{\text{in}} &= \dot{W}_{\text{comp I, in}} + \dot{W}_{\text{comp II, in}} = \dot{m}_A (h_4 - h_9) + \dot{m}_B (h_2 - h_1) \\ &= (0.25 \text{ kg/s})(287.31 - 269.15) \text{ kJ/kg} + (0.1868 \text{ kg/s})(271.42 - 234.46) \text{ kJ/kg} \\ &= 11.44 \text{ kW} \end{aligned}$$

(c) The coefficient of performance is determined from

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{\text{net, in}}} = \frac{28.57 \text{ kW}}{11.44 \text{ kW}} = \mathbf{2.50}$$

11-55 Problem 11-53 is reconsidered. The effects of the various refrigerants in EES data bank for compressor efficiencies of 80, 90, and 100 percent is to be investigated.

Analysis The problem is solved using EES, and the results are tabulated and plotted below.

11-56 A two-stage cascade refrigeration system is considered. Each stage operates on the ideal vapor-compression cycle with refrigerant-134a as the working fluid. The mass flow rate of refrigerant through the lower cycle, the rate of heat removal from the refrigerated space, the power input to the compressor, and the COP of this cascade refrigerator are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible. 3 The heat exchanger is adiabatic.

Analysis (a) Each stage of the cascade refrigeration cycle is said to operate on the ideal vapor compression refrigeration cycle. Thus the compression process is isentropic, and the refrigerant enters the compressor as a saturated vapor at the evaporator pressure. Also, the refrigerant leaves the condenser as a saturated liquid at the condenser pressure. The enthalpies of the refrigerant at all 8 states are determined from the refrigerant tables (Tables A-11, A-12, and A-13) to be

$$\begin{aligned} h_1 &= 239.19 \text{ kJ/kg}, & h_2 &= 260.61 \text{ kJ/kg} \\ h_3 &= 63.92 \text{ kJ/kg}, & h_4 &= 63.92 \text{ kJ/kg} \\ h_5 &= 255.61 \text{ kJ/kg}, & h_6 &= 269.96 \text{ kJ/kg} \\ h_7 &= 95.48 \text{ kJ/kg}, & h_8 &= 95.48 \text{ kJ/kg} \end{aligned}$$

The mass flow rate of the refrigerant through the lower cycle is determined from an energy balance on the heat exchanger:

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \stackrel{\phi^0(\text{steady})}{=} 0 \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \sum \dot{m}_e h_e &= \sum \dot{m}_i h_i \\ \dot{m}_A (h_5 - h_8) &= \dot{m}_B (h_2 - h_3) \\ \dot{m}_B &= \frac{h_5 - h_8}{h_2 - h_3} \dot{m}_A = \frac{255.61 - 95.48}{260.61 - 63.92} (0.24 \text{ kg/s}) = \mathbf{0.1954 \text{ kg/s}} \end{aligned}$$

(b) The rate of heat removed by a cascade cycle is the rate of heat absorption in the evaporator of the lowest stage. The power input to a cascade cycle is the sum of the power inputs to all of the compressors:

$$\begin{aligned} \dot{Q}_L &= \dot{m}_B (h_1 - h_4) = (0.1954 \text{ kg/s})(239.19 - 63.92) \text{ kJ/kg} = \mathbf{34.25 \text{ kW}} \\ \dot{W}_{\text{in}} &= \dot{W}_{\text{comp I, in}} + \dot{W}_{\text{comp II, in}} = \dot{m}_A (h_6 - h_5) + \dot{m}_B (h_2 - h_1) \\ &= (0.24 \text{ kg/s})(269.96 - 255.61) \text{ kJ/kg} + (0.1954 \text{ kg/s})(260.61 - 239.19) \text{ kJ/kg} \\ &= \mathbf{7.631 \text{ kW}} \end{aligned}$$

(c) The COP of this refrigeration system is determined from its definition,

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{\text{net, in}}} = \frac{34.25 \text{ kW}}{7.631 \text{ kW}} = \mathbf{4.488}$$

11-57 A two-stage cascade refrigeration system is considered. Each stage operates on the ideal vapor-compression cycle with refrigerant-134a as the working fluid. The mass flow rate of refrigerant through the lower cycle, the rate of heat removal from the refrigerated space, the power input to the compressor, and the COP of this cascade refrigerator are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible. 3 The heat exchanger is adiabatic.

Analysis (a) Each stage of the cascade refrigeration cycle is said to operate on the ideal vapor compression refrigeration cycle. Thus the compression process is isentropic, and the refrigerant enters the compressor as a saturated vapor at the evaporator pressure. Also, the refrigerant leaves the condenser as a saturated liquid at the condenser pressure. The enthalpies of the refrigerant at all 8 states are determined from the refrigerant tables (Tables A-11, A-12, and A-13) to be

$$\begin{aligned} h_1 &= 239.19 \text{ kJ/kg}, & h_2 &= 267.37 \text{ kJ/kg} \\ h_3 &= 77.54 \text{ kJ/kg}, & h_4 &= 77.54 \text{ kJ/kg} \\ h_5 &= 260.98 \text{ kJ/kg}, & h_6 &= 268.71 \text{ kJ/kg} \\ h_7 &= 95.48 \text{ kJ/kg}, & h_8 &= 95.48 \text{ kJ/kg} \end{aligned}$$

The mass flow rate of the refrigerant through the lower cycle is determined from an energy balance on the heat exchanger:

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\phi=0(\text{steady})}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_e h_e = \sum \dot{m}_i h_i$$

$$\dot{m}_A (h_5 - h_8) = \dot{m}_B (h_2 - h_3)$$

$$\dot{m}_B = \frac{h_5 - h_8}{h_2 - h_3} \dot{m}_A = \frac{260.98 - 95.48}{267.37 - 77.54} (0.24 \text{ kg/s}) = \mathbf{0.2092 \text{ kg/s}}$$

(b) The rate of heat removed by a cascade cycle is the rate of heat absorption in the evaporator of the lowest stage. The power input to a cascade cycle is the sum of the power inputs to all of the compressors:

$$\dot{Q}_L = \dot{m}_B (h_1 - h_4) = (0.2092 \text{ kg/s})(239.19 - 77.54) \text{ kJ/kg} = \mathbf{33.82 \text{ kW}}$$

$$\begin{aligned} \dot{W}_{\text{in}} &= \dot{W}_{\text{compI,in}} + \dot{W}_{\text{compII,in}} = \dot{m}_A (h_6 - h_5) + \dot{m}_B (h_2 - h_1) \\ &= (0.24 \text{ kg/s})(268.71 - 260.98) \text{ kJ/kg} + (0.2092 \text{ kg/s})(267.37 - 239.19) \text{ kJ/kg} \\ &= \mathbf{7.752 \text{ kW}} \end{aligned}$$

(c) The COP of this refrigeration system is determined from its definition,

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{\text{net,in}}} = \frac{33.82 \text{ kW}}{7.752 \text{ kW}} = \mathbf{4.363}$$

11-58 A two-stage cascade refrigeration cycle is considered. The mass flow rate of the refrigerant through the upper cycle, the rate of heat removal from the refrigerated space, and the COP of the refrigerator are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) The properties are to be obtained from the refrigerant tables (Tables A-11 through A-13):

$$h_1 = h_{g@160\text{kPa}} = 241.14 \text{ kJ/kg}$$

$$s_1 = s_{g@160\text{kPa}} = 0.9420 \text{ kJ/kg}\cdot\text{K}$$

$$\left. \begin{array}{l} P_2 = 500 \text{ kPa} \\ s_2 = s_1 \end{array} \right\} h_{2s} = 264.55 \text{ kJ/kg}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1}$$

$$0.80 = \frac{264.55 - 241.14}{h_2 - 241.14} \longrightarrow h_2 = 270.41 \text{ kJ/kg}$$

$$h_3 = h_{f@500\text{kPa}} = 73.32 \text{ kJ/kg}$$

$$h_4 = h_3 = 73.32 \text{ kJ/kg}$$

$$h_5 = h_{g@400\text{kPa}} = 255.61 \text{ kJ/kg}$$

$$s_5 = s_{g@400\text{kPa}} = 0.9271 \text{ kJ/kg}\cdot\text{K}$$

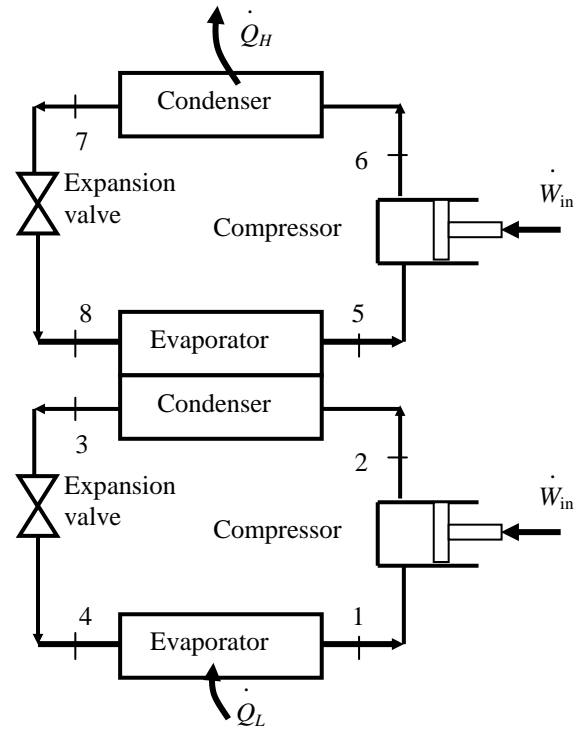

$$\left. \begin{array}{l} P_6 = 1400 \text{ kPa} \\ s_6 = s_5 \end{array} \right\} h_{6s} = 281.56 \text{ kJ/kg}$$

$$\eta_C = \frac{h_{6s} - h_5}{h_6 - h_5}$$

$$0.80 = \frac{281.56 - 255.61}{h_6 - 255.61} \longrightarrow h_6 = 288.04 \text{ kJ/kg}$$

$$h_7 = h_{f@1400\text{kPa}} = 127.25 \text{ kJ/kg}$$

$$h_8 = h_7 = 127.25 \text{ kJ/kg}$$

The mass flow rate of the refrigerant through the upper cycle is determined from an energy balance on the heat exchanger

$$\dot{m}_A(h_5 - h_8) = \dot{m}_B(h_2 - h_3)$$

$$\dot{m}_A(255.61 - 127.25) \text{ kJ/kg} = (0.11 \text{ kg/s})(270.41 - 73.32) \text{ kJ/kg} \longrightarrow \dot{m}_A = \mathbf{0.1689 \text{ kg/s}}$$

(b) The rate of heat removal from the refrigerated space is

$$\dot{Q}_L = \dot{m}_B(h_1 - h_4) = (0.11 \text{ kg/s})(241.14 - 73.32) \text{ kJ/kg} = \mathbf{18.46 \text{ kW}}$$

(c) The power input and the COP are

$$\dot{W}_{\text{in}} = \dot{m}_A(h_6 - h_5) + \dot{m}_B(h_2 - h_1)$$

$$= (0.11 \text{ kg/s})(288.04 - 255.61) \text{ kJ/kg} + (0.1689 \text{ kg/s})(270.41 - 241.14) \text{ kJ/kg}$$

$$= 8.698 \text{ kW}$$

$$\text{COP} = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} = \frac{18.46}{8.698} = \mathbf{2.12}$$

11-59 A two-stage cascade refrigeration cycle with a flash chamber is considered. The mass flow rate of the refrigerant through the high-pressure compressor, the rate of heat removal from the refrigerated space, the COP of the refrigerator, and the rate of heat removal and the COP if this refrigerator operated on a single-stage cycle between the same pressure limits are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) The properties are to be obtained from the refrigerant tables (Tables A-11 through A-13):

$$h_1 = h_{g@200\text{kPa}} = 244.50 \text{ kJ/kg}$$

$$s_1 = s_{g@200\text{kPa}} = 0.9379 \text{ kJ/kg}\cdot\text{K}$$

$$\left. \begin{array}{l} P_2 = 450 \text{ kPa} \\ s_2 = s_1 \end{array} \right\} h_{2s} = 261.13 \text{ kJ/kg}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1}$$

$$0.80 = \frac{261.13 - 244.50}{h_2 - 244.50} \longrightarrow h_2 = 265.28 \text{ kJ/kg}$$

$$h_3 = h_{g@450\text{kPa}} = 257.58 \text{ kJ/kg}$$

$$h_5 = h_{f@1200\text{kPa}} = 117.79 \text{ kJ/kg}$$

$$h_6 = h_5 = 117.79 \text{ kJ/kg}$$

$$h_7 = h_{f@450\text{kPa}} = 68.80 \text{ kJ/kg}$$

$$h_8 = h_7 = 68.810 \text{ kJ/kg}$$

$$\left. \begin{array}{l} h_6 = 117.79 \text{ kJ/kg} \\ P_6 = 450 \text{ kPa} \end{array} \right\} x_6 = 0.2595$$

The mass flow rate of the refrigerant through the high pressure compressor is determined from a mass balance on the flash chamber

$$\dot{m} = \frac{\dot{m}_7}{1 - x_6} = \frac{0.15 \text{ kg/s}}{1 - 0.2595} = \mathbf{0.2026 \text{ kg/s}}$$

Also,

$$\dot{m}_3 = \dot{m} - \dot{m}_7 = 0.2026 - 0.15 = 0.05257 \text{ kg/s}$$

(b) The enthalpy at state 9 is determined from an energy balance on the mixing chamber:

$$\dot{m}h_9 = \dot{m}_7h_2 + \dot{m}_3h_3$$

$$(0.2026 \text{ kg/s})h_9 = (0.15 \text{ kg/s})(265.28 \text{ kJ/kg}) + (0.05257 \text{ kg/s})(257.58 \text{ kJ/kg}) \longrightarrow h_9 = 263.28 \text{ kJ/kg}$$

Then,

$$\left. \begin{array}{l} P_9 = 450 \text{ kPa} \\ h_9 = 263.28 \text{ kJ/kg} \end{array} \right\} s_9 = 0.9453 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_4 = 1200 \text{ kPa} \\ s_4 = s_9 \end{array} \right\} h_{4s} = 284.32 \text{ kJ/kg}$$

$$\eta_C = \frac{h_{4s} - h_9}{h_4 - h_9}$$

$$0.80 = \frac{284.32 - 263.28}{h_4 - 263.28} \longrightarrow h_4 = 289.57 \text{ kJ/kg}$$

The rate of heat removal from the refrigerated space is

$$\dot{Q}_L = \dot{m}_7(h_1 - h_8) = (0.15 \text{ kg/s})(244.50 - 68.80) \text{ kJ/kg} = \mathbf{26.35 \text{ kW}}$$

(c) The power input and the COP are

$$\begin{aligned} \dot{W}_{\text{in}} &= \dot{m}_7(h_2 - h_1) + \dot{m}(h_4 - h_9) \\ &= (0.15 \text{ kg/s})(265.28 - 244.50) \text{ kJ/kg} + (0.2026 \text{ kg/s})(289.57 - 263.28) \text{ kJ/kg} \\ &= 8.444 \text{ kW} \end{aligned}$$

$$\text{COP} = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} = \frac{26.35}{8.444} = \mathbf{3.12}$$

(d) If this refrigerator operated on a single-stage cycle between the same pressure limits, we would have

$$h_1 = h_g @ 200 \text{ kPa} = 244.50 \text{ kJ/kg}$$

$$s_1 = s_g @ 200 \text{ kPa} = 0.9379 \text{ kJ/kg}\cdot\text{K}$$

$$\left. \begin{array}{l} P_2 = 1200 \text{ kPa} \\ s_2 = s_1 \end{array} \right\} h_{2s} = 281.88 \text{ kJ/kg}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1}$$

$$0.80 = \frac{281.88 - 244.50}{h_2 - 244.50} \longrightarrow h_2 = 291.23 \text{ kJ/kg}$$

$$h_3 = h_f @ 1200 \text{ kPa} = 117.79 \text{ kJ/kg}$$

$$h_4 = h_3 = 117.79 \text{ kJ/kg}$$

$$\dot{Q}_L = \dot{m}(h_1 - h_4) = (0.2026 \text{ kg/s})(244.50 - 117.79) \text{ kJ/kg} = \mathbf{25.67 \text{ kW}}$$

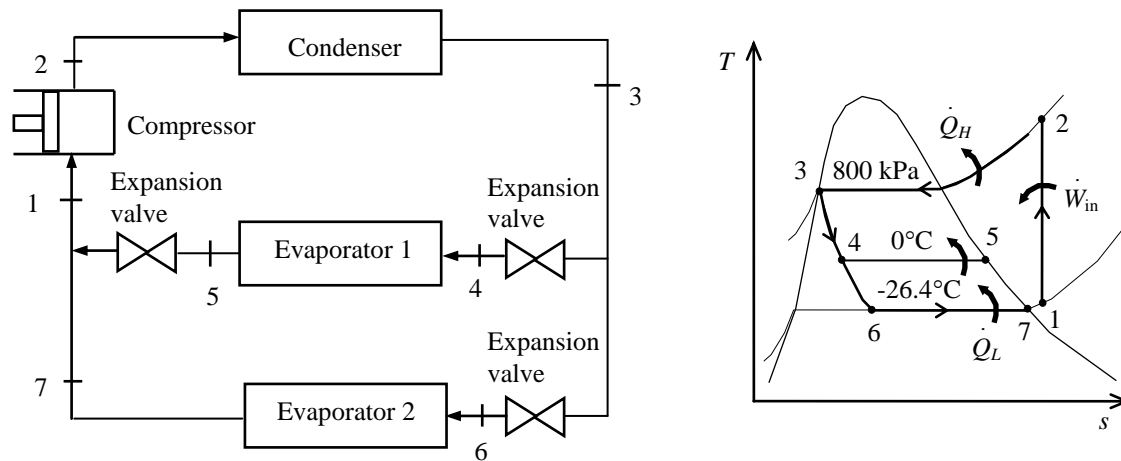

$$\dot{W}_{\text{in}} = \dot{m}(h_2 - h_1) = (0.2026 \text{ kg/s})(291.23 - 244.50) \text{ kJ/kg} = 9.467 \text{ kW}$$

$$\text{COP} = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} = \frac{25.67}{9.467} = \mathbf{2.71}$$

11-60 A two-evaporator compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The cooling rate of the high-temperature evaporator, the power required by the compressor, and the COP of the system are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the refrigerant tables (Tables A-11, A-12, and A-13),

$$\left. \begin{array}{l} P_3 = 800 \text{ kPa} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 800 \text{ kPa} = 95.48 \text{ kJ/kg}$$

$$h_4 = h_6 \cong h_3 = 95.48 \text{ kJ/kg} \quad (\text{throttling})$$

$$\left. \begin{array}{l} T_5 = 0^\circ\text{C} \\ \text{sat. vapor} \end{array} \right\} h_5 = h_g @ 0^\circ\text{C} = 250.50 \text{ kJ/kg}$$

$$\left. \begin{array}{l} T_7 = -26.4^\circ\text{C} \\ \text{sat. vapor} \end{array} \right\} h_7 = h_g @ -26.4^\circ\text{C} = 234.44 \text{ kJ/kg}$$

The mass flow rate through the low-temperature evaporator is found by

$$\dot{Q}_L = \dot{m}_2(h_7 - h_6) \longrightarrow \dot{m}_2 = \frac{\dot{Q}_L}{h_7 - h_6} = \frac{8 \text{ kJ/s}}{(234.44 - 95.48) \text{ kJ/kg}} = 0.05757 \text{ kg/s}$$

The mass flow rate through the warmer evaporator is then

$$\dot{m}_1 = \dot{m} - \dot{m}_2 = 0.1 - 0.05757 = 0.04243 \text{ kg/s}$$

Applying an energy balance to the point in the system where the two evaporator streams are recombined gives

$$\dot{m}_1 h_5 + \dot{m}_2 h_7 = \dot{m} h_1 \longrightarrow h_1 = \frac{\dot{m}_1 h_5 + \dot{m}_2 h_7}{\dot{m}} = \frac{(0.04243)(250.50) + (0.05757)(234.44)}{0.1} = 241.26 \text{ kJ/kg}$$

Then,

$$\left. \begin{array}{l} P_1 = P_{\text{sat}} @ -26.4^\circ\text{C} \cong 100 \text{ kPa} \\ h_1 = 241.26 \text{ kJ/kg} \end{array} \right\} s_1 = 0.9791 \text{ kJ/kg} \cdot \text{K}$$

$$\left. \begin{array}{l} P_2 = 800 \text{ kPa} \\ s_2 = s_1 \end{array} \right\} h_2 = 286.32 \text{ kJ/kg}$$

The cooling rate of the high-temperature evaporator is

$$\dot{Q}_L = \dot{m}_1(h_5 - h_4) = (0.04243 \text{ kg/s})(250.50 - 95.48) \text{ kJ/kg} = \mathbf{6.578 \text{ kW}}$$

The power input to the compressor is

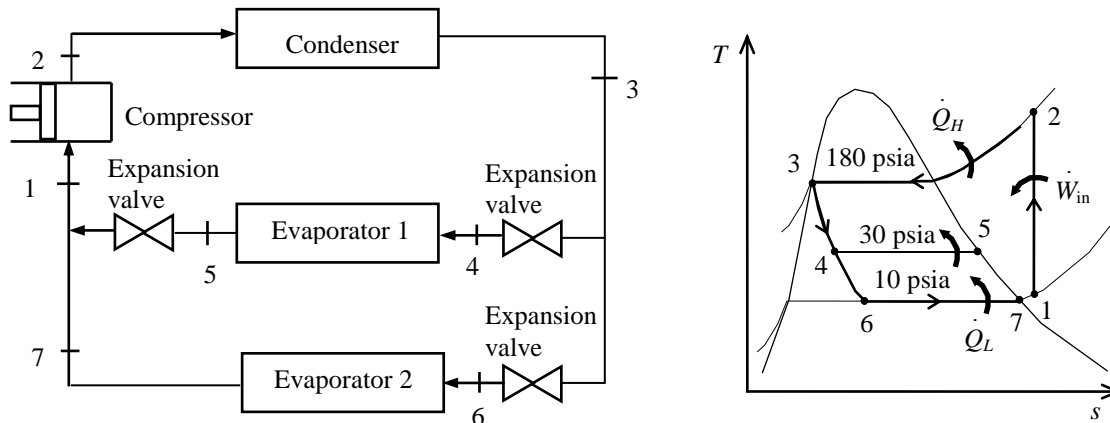

$$\dot{W}_{\text{in}} = \dot{m}(h_2 - h_1) = (0.1 \text{ kg/s})(286.32 - 241.26) \text{ kJ/kg} = \mathbf{4.506 \text{ kW}}$$

The COP of this refrigeration system is determined from its definition,

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} = \frac{(8 + 6.578) \text{ kW}}{4.506 \text{ kW}} = \mathbf{3.24}$$

11-61E A two-evaporator compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The power required by the compressor and the COP of the system are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the refrigerant tables (Tables A-11E, A-12E, and A-13E),

$$\left. \begin{array}{l} P_3 = 180 \text{ psia} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 180 \text{ psia} = 51.51 \text{ Btu/lbm}$$

$$h_4 = h_6 \cong h_3 = 51.51 \text{ Btu/lbm} \quad (\text{throttling})$$

$$\left. \begin{array}{l} P_5 = 30 \text{ psia} \\ \text{sat. vapor} \end{array} \right\} h_5 = h_g @ 30 \text{ psia} = 105.34 \text{ Btu/lbm}$$

$$\left. \begin{array}{l} P_7 = 10 \text{ psia} \\ \text{sat. vapor} \end{array} \right\} h_7 = h_g @ 10 \text{ psia} = 98.69 \text{ Btu/lbm}$$

The mass flow rates through the high-temperature and low-temperature evaporators are found by

$$\dot{Q}_{L,1} = \dot{m}_1 (h_5 - h_4) \longrightarrow \dot{m}_1 = \frac{\dot{Q}_{L,1}}{h_5 - h_4} = \frac{9000 \text{ Btu/h}}{(105.34 - 51.51) \text{ Btu/lbm}} = 167.2 \text{ lbm/h}$$

$$\dot{Q}_{L,2} = \dot{m}_2 (h_7 - h_6) \longrightarrow \dot{m}_2 = \frac{\dot{Q}_{L,2}}{h_7 - h_6} = \frac{24,000 \text{ Btu/h}}{(98.69 - 51.51) \text{ Btu/lbm}} = 508.7 \text{ lbm/h}$$

Applying an energy balance to the point in the system where the two evaporator streams are recombined gives

$$\dot{m}_1 h_5 + \dot{m}_2 h_7 = (\dot{m}_1 + \dot{m}_2) h_1 \longrightarrow h_1 = \frac{\dot{m}_1 h_5 + \dot{m}_2 h_7}{\dot{m}_1 + \dot{m}_2} = \frac{(167.2)(105.34) + (508.7)(98.69)}{167.2 + 508.7} = 100.33 \text{ Btu/lbm}$$

Then,

$$\left. \begin{array}{l} P_1 = 10 \text{ psia} \\ h_1 = 100.33 \text{ Btu/lbm} \end{array} \right\} s_1 = 0.2333 \text{ Btu/lbm} \cdot \text{R}$$

$$\left. \begin{array}{l} P_2 = 180 \text{ psia} \\ s_2 = s_1 \end{array} \right\} h_2 = 127.06 \text{ Btu/lbm}$$

The power input to the compressor is

$$\dot{W}_{\text{in}} = (\dot{m}_1 + \dot{m}_2)(h_2 - h_1) = (167.2 + 508.7) \text{ lbm/h}(127.06 - 100.33) \text{ Btu/lbm} \left(\frac{1 \text{ kW}}{3412.14 \text{ Btu/h}} \right) = \mathbf{5.293 \text{ kW}}$$

The COP of this refrigeration system is determined from its definition,

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} = \frac{(24,000 + 9000) \text{ Btu/h}}{5.293 \text{ kW}} \left(\frac{1 \text{ kW}}{3412.14 \text{ Btu/h}} \right) = \mathbf{1.83}$$

11-62E A two-evaporator compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The power required by the compressor and the COP of the system are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the refrigerant tables (Tables A-11E, A-12E, and A-13E),

$$\left. \begin{array}{l} P_3 = 180 \text{ psia} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 180 \text{ psia} = 51.51 \text{ Btu/lbm}$$

$$h_4 = h_6 \cong h_3 = 51.51 \text{ Btu/lbm} \quad (\text{throttling})$$

$$\left. \begin{array}{l} P_5 = 60 \text{ psia} \\ \text{sat. vapor} \end{array} \right\} h_5 = h_g @ 60 \text{ psia} = 110.13 \text{ Btu/lbm}$$

$$\left. \begin{array}{l} P_7 = 10 \text{ psia} \\ \text{sat. vapor} \end{array} \right\} h_7 = h_g @ 10 \text{ psia} = 98.69 \text{ Btu/lbm}$$

The mass flow rates through the high-temperature and low-temperature evaporators are found by

$$\dot{Q}_{L,1} = \dot{m}_1 (h_5 - h_4) \longrightarrow \dot{m}_1 = \frac{\dot{Q}_{L,1}}{h_5 - h_4} = \frac{15,000 \text{ Btu/h}}{(110.13 - 51.51) \text{ Btu/lbm}} = 255.9 \text{ lbm/h}$$

$$\dot{Q}_{L,2} = \dot{m}_2 (h_7 - h_6) \longrightarrow \dot{m}_2 = \frac{\dot{Q}_{L,2}}{h_7 - h_6} = \frac{24,000 \text{ Btu/h}}{(98.69 - 51.51) \text{ Btu/lbm}} = 508.7 \text{ lbm/h}$$

Applying an energy balance to the point in the system where the two evaporator streams are recombined gives

$$\dot{m}_1 h_5 + \dot{m}_2 h_7 = (\dot{m}_1 + \dot{m}_2) h_1 \longrightarrow h_1 = \frac{\dot{m}_1 h_5 + \dot{m}_2 h_7}{\dot{m}_1 + \dot{m}_2} = \frac{(255.9)(110.13) + (508.7)(98.69)}{255.9 + 508.7} = 102.52 \text{ Btu/lbm}$$

Then,

$$\left. \begin{array}{l} P_1 = 10 \text{ psia} \\ h_1 = 102.52 \text{ Btu/lbm} \end{array} \right\} s_1 = 0.2382 \text{ Btu/lbm} \cdot \text{R}$$

$$\left. \begin{array}{l} P_2 = 180 \text{ psia} \\ s_2 = s_1 \end{array} \right\} h_2 = 130.08 \text{ Btu/lbm}$$

The power input to the compressor is

$$\dot{W}_{\text{in}} = (\dot{m}_1 + \dot{m}_2)(h_2 - h_1) = (255.9 + 508.7) \text{ lbm/h}(130.08 - 102.52) \text{ Btu/lbm} \left(\frac{1 \text{ kW}}{3412.14 \text{ Btu/h}} \right) = \mathbf{6.176 \text{ kW}}$$

The COP of this refrigeration system is determined from its definition,

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} = \frac{(24,000 + 15,000) \text{ Btu/h}}{6.176 \text{ kW}} \left(\frac{1 \text{ kW}}{3412.14 \text{ Btu/h}} \right) = \mathbf{1.85}$$

Gas Refrigeration Cycles

11-63C In the ideal gas refrigeration cycle, the heat absorption and the heat rejection processes occur at constant pressure instead of at constant temperature.

11-64C The reversed Stirling cycle is identical to the Stirling cycle, except it operates in the reversed direction. Remembering that the Stirling cycle is a totally reversible cycle, the reversed Stirling cycle is also totally reversible, and thus its COP is

$$\text{COP}_{\text{R,Stirling}} = \frac{1}{T_H/T_L - 1}$$

11-65C In aircraft cooling, the atmospheric air is compressed by a compressor, cooled by the surrounding air, and expanded in a turbine. The cool air leaving the turbine is then directly routed to the cabin.

11-66C No; because $h = h(T)$ for ideal gases, and the temperature of air will not drop during a throttling ($h_1 = h_2$) process.

11-67C By regeneration.

11-68E An ideal-gas refrigeration cycle with air as the working fluid is considered. The rate of refrigeration, the net power input, and the COP are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Air is an ideal gas with variable specific heats. 3 Kinetic and potential energy changes are negligible.

Analysis (a) We assume both the turbine and the compressor to be isentropic, the turbine inlet temperature to be the temperature of the surroundings, and the compressor inlet temperature to be the temperature of the refrigerated space. From the air table (Table A-17E),

$$T_1 = 500 \text{ R} \longrightarrow \begin{aligned} h_1 &= 119.48 \text{ Btu/lbm} \\ P_{r_1} &= 1.0590 \end{aligned}$$

$$T_3 = 580 \text{ R} \longrightarrow \begin{aligned} h_3 &= 138.66 \text{ Btu/lbm} \\ P_{r_3} &= 1.7800 \end{aligned}$$

Thus,

$$P_2 = \frac{P_2}{P_1} P_1 = \left(\frac{30}{10}\right)(1.0590) = 3.177 \longrightarrow \begin{aligned} T_2 &= 683.9 \text{ R} \\ h_2 &= 163.68 \text{ Btu/lbm} \end{aligned}$$

$$P_4 = \frac{P_4}{P_3} P_3 = \left(\frac{10}{30}\right)(1.7800) = 0.5933 \longrightarrow \begin{aligned} T_4 &= 423.4 \text{ R} \\ h_4 &= 101.14 \text{ Btu/lbm} \end{aligned}$$

Then the rate of refrigeration is

$$\dot{Q}_{\text{refrig}} = \dot{m}(q_L) = \dot{m}(h_1 - h_4) = (0.5 \text{ lbm/s})(119.48 - 101.14) \text{ Btu/lbm} = \mathbf{9.17 \text{ Btu/s}}$$

(b) The net power input is determined from

$$\dot{W}_{\text{net, in}} = \dot{W}_{\text{comp, in}} - \dot{W}_{\text{turb, out}}$$

where

$$\dot{W}_{\text{comp, in}} = \dot{m}(h_2 - h_1) = (0.5 \text{ lbm/s})(163.68 - 119.48) \text{ Btu/lbm} = 22.10 \text{ Btu/s}$$

$$\dot{W}_{\text{turb, out}} = \dot{m}(h_3 - h_4) = (0.5 \text{ lbm/s})(138.66 - 101.14) \text{ Btu/lbm} = 18.79 \text{ Btu/s}$$

Thus,

$$\dot{W}_{\text{net, in}} = 22.10 - 18.76 = 3.34 \text{ Btu/s} = \mathbf{4.73 \text{ hp}}$$

(c) The COP of this ideal gas refrigeration cycle is determined from

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{\text{net, in}}} = \frac{9.17 \text{ Btu/s}}{3.34 \text{ Btu/s}} = \mathbf{2.75}$$

11-69 An ideal-gas refrigeration cycle with air as the working fluid is considered. The maximum and minimum temperatures in the cycle, the COP, and the rate of refrigeration are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Air is an ideal gas with variable specific heats. 3 Kinetic and potential energy changes are negligible.

Analysis (a) We assume both the turbine and the compressor to be isentropic, the turbine inlet temperature to be the temperature of the surroundings, and the compressor inlet temperature to be the temperature of the refrigerated space. From the air table (Table A-17),

$$T_1 = 250 \text{ K} \longrightarrow \begin{aligned} h_1 &= 250.05 \text{ kJ/kg} \\ P_{r_1} &= 0.7329 \end{aligned}$$

$$T_3 = 300 \text{ K} \longrightarrow \begin{aligned} h_3 &= 300.19 \text{ kJ/kg} \\ P_{r_3} &= 1.386 \end{aligned}$$

Thus,

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = (3)(0.7329) = 2.1987 \longrightarrow \begin{aligned} T_2 = T_{\max} &= \mathbf{342.2 \text{ K}} \\ h_2 &= 342.60 \text{ kJ/kg} \end{aligned}$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \left(\frac{1}{3}\right)(1.386) = 0.462 \longrightarrow \begin{aligned} T_4 = T_{\min} &= \mathbf{219.0 \text{ K}} \\ h_4 &= 218.97 \text{ kJ/kg} \end{aligned}$$

(b) The COP of this ideal gas refrigeration cycle is determined from

$$\text{COP}_R = \frac{q_L}{w_{\text{net, in}}} = \frac{q_L}{w_{\text{comp, in}} - w_{\text{turb, out}}}$$

where

$$\begin{aligned} q_L &= h_1 - h_4 = 250.05 - 218.97 = 31.08 \text{ kJ/kg} \\ w_{\text{comp, in}} &= h_2 - h_1 = 342.60 - 250.05 = 92.55 \text{ kJ/kg} \\ w_{\text{turb, out}} &= h_3 - h_4 = 300.19 - 218.97 = 81.22 \text{ kJ/kg} \end{aligned}$$

Thus,

$$\text{COP}_R = \frac{31.08}{92.55 - 81.22} = \mathbf{2.74}$$

(c) The rate of refrigeration is determined to be

$$\dot{Q}_{\text{refrig}} = \dot{m}(q_L) = (0.08 \text{ kg/s})(31.08 \text{ kJ/kg}) = \mathbf{2.49 \text{ kJ/s}}$$

11-70  An ideal-gas refrigeration cycle with air as the working fluid is considered. The rate of refrigeration, the net power input, and the COP are to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with variable specific heats. **3** Kinetic and potential energy changes are negligible.

Analysis (a) We assume both the turbine and the compressor to be isentropic, the turbine inlet temperature to be the temperature of the surroundings, and the compressor inlet temperature to be the temperature of the refrigerated space. From the air table (Table A-17),

$$T_1 = 280 \text{ K} \longrightarrow h_1 = 280.13 \text{ kJ/kg} \\ P_{r_1} = 1.0889$$

$$T_3 = 310 \text{ K} \longrightarrow h_3 = 310.24 \text{ kJ/kg} \\ P_{r_3} = 1.5546$$

Thus,

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = \left(\frac{160}{35} \right) (1.0889) = 4.978 \longrightarrow T_2 = 431.5 \text{ K} \\ h_2 = 432.96 \text{ kJ/kg}$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \left(\frac{35}{160} \right) (1.5546) = 0.3401 \longrightarrow T_4 = 200.6 \text{ K} \\ h_4 = 200.57 \text{ kJ/kg}$$

Then the rate of refrigeration is

$$\dot{Q}_L = \dot{m}(q_L) = \dot{m}(h_1 - h_4) = (0.2 \text{ kg/s})(280.13 - 200.57) \text{ kJ/kg} = \mathbf{15.9 \text{ kW}}$$

(b) The net power input is determined from

$$\dot{W}_{\text{net, in}} = \dot{W}_{\text{comp, in}} - \dot{W}_{\text{turb, out}}$$

where

$$\dot{W}_{\text{comp, in}} = \dot{m}(h_2 - h_1) = (0.2 \text{ kg/s})(432.96 - 280.13) \text{ kJ/kg} = 30.57 \text{ kW}$$

$$\dot{W}_{\text{turb, out}} = \dot{m}(h_3 - h_4) = (0.2 \text{ kg/s})(310.24 - 200.57) \text{ kJ/kg} = 21.93 \text{ kW}$$

Thus,

$$\dot{W}_{\text{net, in}} = 30.57 - 21.93 = \mathbf{8.64 \text{ kW}}$$

(c) The COP of this ideal gas refrigeration cycle is determined from

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{\text{net, in}}} = \frac{15.9 \text{ kW}}{8.64 \text{ kW}} = \mathbf{1.84}$$

11-71 An ideal-gas refrigeration cycle with air as the working fluid is considered. The rate of refrigeration, the net power input, and the COP are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Air is an ideal gas with variable specific heats. 3 Kinetic and potential energy changes are negligible.

Analysis (a) We assume the turbine inlet temperature to be the temperature of the surroundings, and the compressor inlet temperature to be the temperature of the refrigerated space. From the air table (Table A-17),

$$T_1 = 280 \text{ K} \longrightarrow h_1 = 280.13 \text{ kJ/kg}$$

$$P_{r_1} = 1.0889$$

$$T_3 = 310 \text{ K} \longrightarrow h_3 = 310.24 \text{ kJ/kg}$$

$$P_{r_3} = 1.5546$$

Thus,

$$P_{r_2} = \frac{P_2}{P_1} P_{r_1} = \left(\frac{160}{35} \right) (1.0889) = 4.978 \longrightarrow T_{2s} = 431.5 \text{ K}$$

$$h_{2s} = 432.96 \text{ kJ/kg}$$

$$P_{r_4} = \frac{P_4}{P_3} P_{r_3} = \left(\frac{35}{160} \right) (1.5546) = 0.3401 \longrightarrow T_{4s} = 200.6 \text{ K}$$

$$h_{4s} = 200.57 \text{ kJ/kg}$$

Also,

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} \longrightarrow h_4 = h_3 - \eta_T (h_3 - h_{4s})$$

$$= 310.24 - (0.85)(310.24 - 200.57)$$

$$= 217.02 \text{ kJ/kg}$$

Then the rate of refrigeration is

$$\dot{Q}_L = \dot{m}(q_L) = \dot{m}(h_1 - h_4) = (0.2 \text{ kg/s})(280.13 - 217.02) \text{ kJ/kg} = \mathbf{12.6 \text{ kW}}$$

(b) The net power input is determined from

$$\dot{W}_{\text{net,in}} = \dot{W}_{\text{comp,in}} - \dot{W}_{\text{turb,out}}$$

where

$$\dot{W}_{\text{comp,in}} = \dot{m}(h_2 - h_1) = \dot{m}(h_{2s} - h_1) / \eta_C$$

$$= (0.2 \text{ kg/s})[(432.96 - 280.13) \text{ kJ/kg}] / (0.80) = 38.21 \text{ kW}$$

$$\dot{W}_{\text{turb,out}} = \dot{m}(h_3 - h_4) = (0.2 \text{ kg/s})(310.24 - 217.02) \text{ kJ/kg} = 18.64 \text{ kW}$$

Thus,

$$\dot{W}_{\text{net,in}} = 38.21 - 18.64 = \mathbf{19.6 \text{ kW}}$$

(c) The COP of this ideal gas refrigeration cycle is determined from

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{\text{net,in}}} = \frac{12.6 \text{ kW}}{19.6 \text{ kW}} = \mathbf{0.643}$$

11-72 Problem 11-71 is reconsidered. The effects of compressor and turbine isentropic efficiencies on the rate of refrigeration, the net power input, and the COP are to be investigated.

Analysis The problem is solved using EES, and the solution is given below.

11-73 A gas refrigeration cycle with helium as the working fluid is considered. The minimum temperature in the cycle, the COP, and the mass flow rate of the helium are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Helium is an ideal gas with constant specific heats. 3 Kinetic and potential energy changes are negligible.

Properties The properties of helium are $c_p = 5.1926 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.667$ (Table A-2).

Analysis (a) From the isentropic relations,

$$T_{2s} = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (267 \text{ K})(4)^{0.667/1.667} = 465.0 \text{ K}$$

$$T_{4s} = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = (323 \text{ K}) \left(\frac{1}{4} \right)^{0.667/1.667} = 185.5 \text{ K}$$

and

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} = \frac{T_3 - T_4}{T_3 - T_{4s}} \longrightarrow T_4 = T_3 - \eta_T(T_3 - T_{4s}) = 323 - (0.85)(323 - 185.5) = 206.1 \text{ K} = T_{\min}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} = \frac{T_{2s} - T_1}{T_2 - T_1} \longrightarrow T_2 = T_1 + (T_{2s} - T_1)/\eta_C = 267 + (465.0 - 267)/(0.85) = 499.9 \text{ K}$$

(b) The COP of this gas refrigeration cycle is determined from

$$\begin{aligned} \text{COP}_R &= \frac{q_L}{w_{\text{net,in}}} = \frac{q_L}{w_{\text{comp,in}} - w_{\text{turb,out}}} \\ &= \frac{h_1 - h_4}{(h_2 - h_1) - (h_3 - h_4)} \\ &= \frac{T_1 - T_4}{(T_2 - T_1) - (T_3 - T_4)} \\ &= \frac{267 - 206.1}{(499.9 - 267) - (323 - 206.1)} \\ &= \mathbf{0.525} \end{aligned}$$

(c) The mass flow rate of helium is determined from

$$\dot{m} = \frac{\dot{Q}_{\text{refrig}}}{q_L} = \frac{\dot{Q}_{\text{refrig}}}{h_1 - h_4} = \frac{\dot{Q}_{\text{refrig}}}{c_p(T_1 - T_4)} = \frac{25 \text{ kJ/s}}{(5.1926 \text{ kJ/kg}\cdot\text{K})(267 - 206.1) \text{ K}} = \mathbf{0.0791 \text{ kg/s}}$$

11-74 An ideal-gas refrigeration cycle with air as the working fluid is considered. The lowest temperature that can be obtained by this cycle, the COP, and the mass flow rate of air are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Air is an ideal gas with constant specific heats. 3 Kinetic and potential energy changes are negligible.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2).

Analysis (a) The lowest temperature in the cycle occurs at the turbine exit. From the isentropic relations,

$$T_2 = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (266 \text{ K})(4)^{0.4/1.4} = 395.3 \text{ K} = 122.3^\circ\text{C}$$

$$T_5 = T_4 \left(\frac{P_5}{P_4} \right)^{(k-1)/k} = (258 \text{ K}) \left(\frac{1}{4} \right)^{0.4/1.4} = 173.6 \text{ K} = -99.4^\circ\text{C} = T_{\min}$$

(b) From an energy balance on the regenerator,

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\phi^0(\text{steady})}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_e h_e = \sum \dot{m}_i h_i \longrightarrow \dot{m}(h_3 - h_4) = \dot{m}(h_1 - h_6)$$

or,

$$\dot{m} c_p (T_3 - T_4) = \dot{m} c_p (T_1 - T_6) \longrightarrow T_3 - T_4 = T_1 - T_6$$

or,

$$T_6 = T_1 - T_3 + T_4 = (-7^\circ\text{C}) - 27^\circ\text{C} + (-15^\circ\text{C}) = -49^\circ\text{C}$$

Then the COP of this ideal gas refrigeration cycle is determined from

$$\begin{aligned} \text{COP}_R &= \frac{q_L}{w_{\text{net,in}}} = \frac{q_L}{w_{\text{comp,in}} - w_{\text{turb,out}}} \\ &= \frac{h_6 - h_5}{(h_2 - h_1) - (h_4 - h_3)} \\ &= \frac{T_6 - T_5}{(T_2 - T_1) - (T_4 - T_3)} \\ &= \frac{-49^\circ\text{C} - (-99.4^\circ\text{C})}{[122.3 - (-7)]^\circ\text{C} - [-15 - (-99.4)]^\circ\text{C}} = \mathbf{1.12} \end{aligned}$$

(c) The mass flow rate is determined from

$$\dot{m} = \frac{\dot{Q}_{\text{refrig}}}{q_L} = \frac{\dot{Q}_{\text{refrig}}}{h_6 - h_5} = \frac{\dot{Q}_{\text{refrig}}}{c_p (T_6 - T_5)} = \frac{12 \text{ kJ/s}}{(1.005 \text{ kJ/kg}\cdot^\circ\text{C})[-49 - (-99.4)]^\circ\text{C}} = \mathbf{0.237 \text{ kg/s}}$$

11-75 An ideal-gas refrigeration cycle with air as the working fluid is considered. The lowest temperature that can be obtained by this cycle, the COP, and the mass flow rate of air are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Air is an ideal gas with constant specific heats. 3 Kinetic and potential energy changes are negligible.

Properties The properties of air at room temperature are $c_p = 1.005$ kJ/kg·K and $k = 1.4$ (Table A-2).

Analysis (a) The lowest temperature in the cycle occurs at the turbine exit. From the isentropic relations,

$$T_{2s} = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (266 \text{ K})(4)^{0.4/1.4} = 395.3 \text{ K} = 122.3^\circ\text{C}$$

$$T_{5s} = T_4 \left(\frac{P_5}{P_4} \right)^{(k-1)/k} = (258 \text{ K}) \left(\frac{1}{4} \right)^{0.4/1.4} = 173.6 \text{ K} = -99.4^\circ\text{C}$$

and

$$\eta_T = \frac{h_4 - h_5}{h_4 - h_{5s}} = \frac{T_4 - T_5}{T_4 - T_{5s}} \longrightarrow T_5 = T_4 - \eta_T(T_4 - T_{5s}) = -15 - (0.80)(-15 - (-99.4)) = -82.5^\circ\text{C} = T_{\min}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} = \frac{T_{2s} - T_1}{T_2 - T_1} \longrightarrow T_2 = T_1 + (T_{2s} - T_1)/\eta_C = -7 + (122.3 - (-7))/(0.75) = 165.4^\circ\text{C}$$

(b) From an energy balance on the regenerator,

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \stackrel{\neq 0 \text{ (steady)}}{=} 0 \longrightarrow \dot{E}_{\text{in}} = \dot{E}_{\text{out}} \\ \sum \dot{m}_e h_e &= \sum \dot{m}_i h_i \longrightarrow \dot{m}(h_3 - h_4) = \dot{m}(h_1 - h_6) \end{aligned}$$

or,

$$\dot{m} c_p (T_3 - T_4) = \dot{m} c_p (T_1 - T_6) \longrightarrow T_3 - T_4 = T_1 - T_6$$

or,

$$T_6 = T_1 - T_3 + T_4 = (-7^\circ\text{C}) - 27^\circ\text{C} + (-15^\circ\text{C}) = -49^\circ\text{C}$$

Then the COP of this ideal gas refrigeration cycle is determined from

$$\begin{aligned} \text{COP}_R &= \frac{q_L}{w_{\text{net,in}}} = \frac{q_L}{w_{\text{comp,in}} - w_{\text{turb,out}}} \\ &= \frac{h_6 - h_5}{(h_2 - h_1) - (h_4 - h_5)} \\ &= \frac{T_6 - T_5}{(T_2 - T_1) - (T_4 - T_5)} \\ &= \frac{-49^\circ\text{C} - (-82.5^\circ\text{C})}{[165.4 - (-7)]^\circ\text{C} - [-15 - (-82.5)]^\circ\text{C}} = \mathbf{0.32} \end{aligned}$$

(c) The mass flow rate is determined from

$$\dot{m} = \frac{\dot{Q}_{\text{refrig}}}{q_L} = \frac{\dot{Q}_{\text{refrig}}}{h_6 - h_5} = \frac{\dot{Q}_{\text{refrig}}}{c_p(T_6 - T_5)} = \frac{12 \text{ kJ/s}}{(1.005 \text{ kJ/kg}\cdot^\circ\text{C})[-49 - (-82.5)]^\circ\text{C}} = \mathbf{0.356 \text{ kg/s}}$$

11-76 A regenerative gas refrigeration cycle using air as the working fluid is considered. The effectiveness of the regenerator, the rate of heat removal from the refrigerated space, the COP of the cycle, and the refrigeration load and the COP if this system operated on the simple gas refrigeration cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with constant specific heats.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2).

Analysis (a) From the isentropic relations,

$$T_{2s} = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (273.2 \text{ K})(5)^{0.4/1.4} = 432.4 \text{ K}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} = \frac{T_{2s} - T_1}{T_2 - T_1}$$

$$0.80 = \frac{432.4 - 273.2}{T_2 - 273.2} \rightarrow T_2 = 472.5 \text{ K}$$

The temperature at state 4 can be determined by solving the following two equations simultaneously:

$$T_{5s} = T_4 \left(\frac{P_5}{P_4} \right)^{(k-1)/k} = T_4 \left(\frac{1}{5} \right)^{0.4/1.4}$$

$$\eta_T = \frac{h_4 - h_5}{h_4 - h_{5s}} \rightarrow 0.85 = \frac{T_4 - 193.2}{T_4 - T_{5s}}$$

Using EES, we obtain $T_4 = 281.3 \text{ K}$.

An energy balance on the regenerator may be written as

$$\dot{m}c_p(T_3 - T_4) = \dot{m}c_p(T_1 - T_6) \rightarrow T_3 - T_4 = T_1 - T_6$$

or,

$$T_6 = T_1 - T_3 + T_4 = 273.2 - 308.2 + 281.3 = 246.3 \text{ K}$$

The effectiveness of the regenerator is

$$\varepsilon_{\text{regen}} = \frac{h_3 - h_4}{h_3 - h_6} = \frac{T_3 - T_4}{T_3 - T_6} = \frac{308.2 - 281.3}{308.2 - 246.3} = \mathbf{0.434}$$

(b) The refrigeration load is

$$\dot{Q}_L = \dot{m}c_p(T_6 - T_5) = (0.4 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(246.3 - 193.2) \text{ K} = \mathbf{21.36 \text{ kW}}$$

(c) The turbine and compressor powers and the COP of the cycle are

$$\dot{W}_{C,\text{in}} = \dot{m}c_p(T_2 - T_1) = (0.4 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(472.5 - 273.2) \text{ K} = 80.13 \text{ kW}$$

$$\dot{W}_{T,\text{out}} = \dot{m}c_p(T_4 - T_5) = (0.4 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(281.3 - 193.2) \text{ K} = 35.43 \text{ kW}$$

$$\text{COP} = \frac{\dot{Q}_L}{\dot{W}_{\text{net,in}}} = \frac{\dot{Q}_L}{\dot{W}_{C,\text{in}} - \dot{W}_{T,\text{out}}} = \frac{21.36}{80.13 - 35.43} = \mathbf{0.478}$$

(d) The simple gas refrigeration cycle analysis is as follows:

$$T_{4s} = T_3 \left(\frac{1}{r} \right)^{(k-1)/k} = (308.2 \text{ K}) \left(\frac{1}{5} \right)^{0.4/1.4} = 194.6 \text{ K}$$

$$\eta_T = \frac{T_3 - T_4}{T_3 - T_{4s}} \rightarrow 0.85 = \frac{308.2 - T_4}{308.2 - 194.6} \rightarrow T_4 = 211.6 \text{ K}$$

$$\begin{aligned} \dot{Q}_L &= \dot{m} c_p (T_1 - T_4) \\ &= (0.4 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(273.2 - 211.6) \text{ kJ/kg} \\ &= \mathbf{24.74 \text{ kW}} \end{aligned}$$

$$\begin{aligned} \dot{W}_{\text{net,in}} &= \dot{m} c_p (T_2 - T_1) - \dot{m} c_p (T_3 - T_4) \\ &= (0.4 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})[(472.5 - 273.2) - (308.2 - 211.6) \text{ kJ/kg}] \\ &= 41.32 \text{ kW} \end{aligned}$$

$$\text{COP} = \frac{\dot{Q}_L}{\dot{W}_{\text{net,in}}} = \frac{24.74}{41.32} = \mathbf{0.599}$$

11-77 An ideal gas refrigeration cycle with two stages of compression with intercooling using air as the working fluid is considered. The COP of this system and the mass flow rate of air are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Air is an ideal gas with constant specific heats. 3 Kinetic and potential energy changes are negligible.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2a).

Analysis From the isentropic relations,

$$T_2 = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (249 \text{ K})(3)^{0.4/1.4} = 340.8 \text{ K}$$

$$T_4 = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = (278 \text{ K})(3)^{0.4/1.4} = 380.5 \text{ K}$$

$$T_6 = T_5 \left(\frac{P_6}{P_5} \right)^{(k-1)/k} = (278 \text{ K}) \left(\frac{1}{9} \right)^{0.4/1.4} = 148.4 \text{ K}$$

The COP of this ideal gas refrigeration cycle is determined from

$$\begin{aligned} \text{COP}_R &= \frac{q_L}{w_{\text{net,in}}} = \frac{q_L}{w_{\text{comp,in}} - w_{\text{turb,out}}} \\ &= \frac{h_1 - h_6}{(h_2 - h_1) + (h_4 - h_3) - (h_5 - h_6)} \\ &= \frac{T_1 - T_6}{(T_2 - T_1) + (T_4 - T_3) - (T_5 - T_6)} \\ &= \frac{249 - 148.4}{(340.8 - 249) + (380.5 - 278) - (278 - 148.4)} \\ &= \mathbf{1.56} \end{aligned}$$

The mass flow rate of the air is determined from

$$\dot{Q}_{\text{Refrig}} = \dot{m} c_p (T_1 - T_6) \longrightarrow \dot{m} = \frac{\dot{Q}_{\text{Refrig}}}{c_p (T_1 - T_6)} = \frac{(45,000/3600) \text{ kJ/s}}{(1.005 \text{ kJ/kg}\cdot\text{K})(249 - 148.4) \text{ K}} = \mathbf{0.124 \text{ kg/s}}$$

11-78 A gas refrigeration cycle with two stages of compression with intercooling using air as the working fluid is considered. The COP of this system and the mass flow rate of air are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Air is an ideal gas with constant specific heats. 3 Kinetic and potential energy changes are negligible.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2a).

Analysis From the isentropic relations,

$$T_{2s} = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (249 \text{ K})(3)^{0.4/1.4} = 340.8 \text{ K}$$

$$T_{4s} = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = (278 \text{ K})(3)^{0.4/1.4} = 380.5 \text{ K}$$

$$T_{6s} = T_5 \left(\frac{P_6}{P_5} \right)^{(k-1)/k} = (278 \text{ K}) \left(\frac{1}{9} \right)^{0.4/1.4} = 148.4 \text{ K}$$

and

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} = \frac{T_{2s} - T_1}{T_2 - T_1} \longrightarrow T_2 = T_1 + (T_{2s} - T_1) / \eta_C = 249 + (340.8 - 249) / 0.85 = 357.0 \text{ K}$$

$$\eta_C = \frac{h_{4s} - h_3}{h_4 - h_3} = \frac{T_{4s} - T_3}{T_4 - T_3} \longrightarrow T_4 = T_3 + (T_{4s} - T_3) / \eta_C = 278 + (380.5 - 278) / 0.85 = 398.6 \text{ K}$$

$$\eta_T = \frac{h_5 - h_6}{h_5 - h_{6s}} = \frac{T_5 - T_6}{T_5 - T_{6s}} \longrightarrow T_6 = T_5 - \eta_T (T_5 - T_{6s}) = 278 - (0.95)(278 - 148.4) = 154.9 \text{ K}$$

The COP of this ideal gas refrigeration cycle is determined from

$$\begin{aligned} \text{COP}_R &= \frac{q_L}{w_{\text{net,in}}} = \frac{q_L}{w_{\text{comp,in}} - w_{\text{turb,out}}} \\ &= \frac{h_1 - h_6}{(h_2 - h_1) + (h_4 - h_3) - (h_5 - h_6)} \\ &= \frac{T_1 - T_6}{(T_2 - T_1) + (T_4 - T_3) - (T_5 - T_6)} \\ &= \frac{249 - 154.9}{(357.0 - 249) + (398.6 - 278) - (278 - 154.9)} = \mathbf{0.892} \end{aligned}$$

The mass flow rate of the air is determined from

$$\dot{Q}_{\text{Refrig}} = \dot{m} c_p (T_1 - T_6) \longrightarrow \dot{m} = \frac{\dot{Q}_{\text{Refrig}}}{c_p (T_1 - T_6)} = \frac{(45,000 / 3600) \text{ kJ/s}}{(1.005 \text{ kJ/kg}\cdot\text{K})(249 - 154.9) \text{ K}} = \mathbf{0.132 \text{ kg/s}}$$

Absorption Refrigeration Systems

11-79C Absorption refrigeration is the kind of refrigeration that involves the absorption of the refrigerant during part of the cycle. In absorption refrigeration cycles, the refrigerant is compressed in the liquid phase instead of in the vapor form.

11-80C The main advantage of absorption refrigeration is its being economical in the presence of an inexpensive heat source. Its disadvantages include being expensive, complex, and requiring an external heat source.

11-81C The fluid in the absorber is cooled to maximize the refrigerant content of the liquid; the fluid in the generator is heated to maximize the refrigerant content of the vapor.

11-82C The coefficient of performance of absorption refrigeration systems is defined as

$$\text{COP}_R = \frac{\text{desired output}}{\text{required input}} = \frac{Q_L}{Q_{\text{gen}} + W_{\text{pump in}}} \cong \frac{Q_L}{Q_{\text{gen}}}$$

11-83 The COP of an absorption refrigeration system that operates at specified conditions is given. It is to be determined whether the given COP value is possible.

Analysis The maximum COP that this refrigeration system can have is

$$\text{COP}_{R,\text{max}} = \left(1 - \frac{T_0}{T_s}\right) \left(\frac{T_L}{T_0 - T_L}\right) = \left(1 - \frac{292 \text{ K}}{368 \text{ K}}\right) \left(\frac{273}{292 - 273}\right) = 2.97$$

which is smaller than 3.1. Thus the claim is **not possible**.

11-84 The conditions at which an absorption refrigeration system operates are specified. The maximum COP this absorption refrigeration system can have is to be determined.

Analysis The maximum COP that this refrigeration system can have is

$$\text{COP}_{R,\text{max}} = \left(1 - \frac{T_0}{T_s}\right) \left(\frac{T_L}{T_0 - T_L}\right) = \left(1 - \frac{298 \text{ K}}{393 \text{ K}}\right) \left(\frac{273}{298 - 273}\right) = \mathbf{2.64}$$

11-85 The conditions at which an absorption refrigeration system operates are specified. The maximum rate at which this system can remove heat from the refrigerated space is to be determined.

Analysis The maximum COP that this refrigeration system can have is

$$\text{COP}_{\text{R,max}} = \left(1 - \frac{T_0}{T_s}\right) \left(\frac{T_L}{T_0 - T_L}\right) = \left(1 - \frac{298 \text{ K}}{383 \text{ K}}\right) \left(\frac{255}{298 - 255}\right) = 1.316$$

Thus,

$$\dot{Q}_{\text{L,max}} = \text{COP}_{\text{R,max}} \dot{Q}_{\text{gen}} = (1.316)(5 \times 10^5 \text{ kJ/h}) = \mathbf{6.58 \times 10^5 \text{ kJ/h}}$$

11-86 A reversible absorption refrigerator consists of a reversible heat engine and a reversible refrigerator. The rate at which the steam condenses, the power input to the reversible refrigerator, and the second law efficiency of an actual chiller are to be determined.

Properties The enthalpy of vaporization of water at 150°C is $h_{fg} = 2113.8 \text{ kJ/kg}$ (Table A-4).

Analysis (a) The thermal efficiency of the reversible heat engine is

$$\eta_{\text{th,rev}} = 1 - \frac{T_0}{T_s} = 1 - \frac{(25 + 273.15) \text{ K}}{(150 + 273.15) \text{ K}} = 0.2954$$

The COP of the reversible refrigerator is

$$\text{COP}_{\text{R,rev}} = \frac{T_L}{T_0 - T_L} = \frac{(-15 + 273.15) \text{ K}}{(25 + 273.15) - (-15 + 273.15) \text{ K}} = 6.454$$

The COP of the reversible absorption refrigerator is

$$\text{COP}_{\text{abs,rev}} = \eta_{\text{th,rev}} \text{COP}_{\text{R,rev}} = (0.2954)(6.454) = 1.906$$

The heat input to the reversible heat engine is

$$\dot{Q}_{\text{in}} = \frac{\dot{Q}_{\text{L}}}{\text{COP}_{\text{abs,rev}}} = \frac{70 \text{ kW}}{1.906} = 36.72 \text{ kW}$$

Then, the rate at which the steam condenses becomes

$$\dot{m}_s = \frac{\dot{Q}_{\text{in}}}{h_{fg}} = \frac{36.72 \text{ kJ/s}}{2113.8 \text{ kJ/kg}} = \mathbf{0.0174 \text{ kg/s}}$$

(b) The power input to the refrigerator is equal to the power output from the heat engine

$$\dot{W}_{\text{in,R}} = \dot{W}_{\text{out,HE}} = \eta_{\text{th,rev}} \dot{Q}_{\text{in}} = (0.2954)(36.72 \text{ kW}) = \mathbf{10.9 \text{ kW}}$$

(c) The second-law efficiency of an actual absorption chiller with a COP of 0.8 is

$$\eta_{\text{II}} = \frac{\text{COP}_{\text{actual}}}{\text{COP}_{\text{abs,rev}}} = \frac{0.8}{1.906} = 0.420 = \mathbf{42.0\%}$$

11-87E An ammonia-water absorption refrigeration cycle is considered. The rate of cooling, the COP, and the second-law efficiency of the system are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Properties The properties of ammonia are as given in the problem statement. The specific heat of geothermal water is given to be 1.0 Btu/lbm·°F.

Analysis (a) The rate of cooling provided by the system is

$$\begin{aligned}\dot{Q}_L &= \dot{m}_R(h_1 - h_4) = (0.04 \text{ lbm/s})(619.2 - 190.9) \text{ Btu/lbm} \\ &= 17.13 \text{ Btu/s} = \mathbf{61,700 \text{ Btu/h}}\end{aligned}$$

(b) The rate of heat input to the generator is

$$\dot{Q}_{\text{gen}} = \dot{m}_{\text{geo}} c_p (T_{\text{geo;in}} - T_{\text{geo;out}}) = (0.55 \text{ lbm/s})(1.0 \text{ Btu/lbm} \cdot \text{°F})(240 - 200) \text{°F} = 22.0 \text{ Btu/s}$$

Then the COP becomes

$$\text{COP} = \frac{\dot{Q}_L}{\dot{Q}_{\text{gen}}} = \frac{17.13 \text{ Btu/s}}{22.0 \text{ Btu/s}} = \mathbf{0.779}$$

(c) The reversible COP of the system is

$$\text{COP}_{\text{abs,rev}} = \left(1 - \frac{T_0}{T_s}\right) \left(\frac{T_L}{T_0 - T_L}\right) = \left(1 - \frac{(70 + 460)}{(220 + 460)}\right) \left(\frac{(25 + 460)}{70 - 25}\right) = 2.38$$

The temperature of the heat source is taken as the average temperature of the geothermal water: $(240 + 200)/2 = 220 \text{°F}$. Then the second-law efficiency becomes

$$\eta_{\text{II}} = \frac{\text{COP}}{\text{COP}_{\text{abs,rev}}} = \frac{0.779}{2.38} = 0.328 = \mathbf{32.8\%}$$

Special Topic: Thermoelectric Power Generation and Refrigeration Systems

11-88C The circuit that incorporates both thermal and electrical effects is called a thermoelectric circuit.

11-89C When two wires made from different metals joined at both ends (junctions) forming a closed circuit and one of the joints is heated, a current flows continuously in the circuit. This is called the Seebeck effect. When a small current is passed through the junction of two dissimilar wires, the junction is cooled. This is called the Peltier effect.

11-90C No.

11-91C No.

11-92C Yes.

11-93C When a thermoelectric circuit is broken, the current will cease to flow, and we can measure the voltage generated in the circuit by a voltmeter. The voltage generated is a function of the temperature difference, and the temperature can be measured by simply measuring voltages.

11-94C The performance of thermoelectric refrigerators improves considerably when semiconductors are used instead of metals.

11-95C The efficiency of a thermoelectric generator is limited by the Carnot efficiency because a thermoelectric generator fits into the definition of a heat engine with electrons serving as the working fluid.

11-96E A thermoelectric generator that operates at specified conditions is considered. The maximum thermal efficiency this thermoelectric generator can have is to be determined.

Analysis The maximum thermal efficiency of this thermoelectric generator is the Carnot efficiency,

$$\eta_{\text{th,max}} = \eta_{\text{th,Carnot}} = 1 - \frac{T_L}{T_H} = 1 - \frac{550\text{R}}{800\text{R}} = \mathbf{31.3\%}$$

11-97 A thermoelectric refrigerator that operates at specified conditions is considered. The maximum COP this thermoelectric refrigerator can have and the minimum required power input are to be determined.

Analysis The maximum COP of this thermoelectric refrigerator is the COP of a Carnot refrigerator operating between the same temperature limits,

$$\text{COP}_{\text{max}} = \text{COP}_{\text{R,Carnot}} = \frac{1}{(T_H / T_L) - 1} = \frac{1}{(293\text{ K}) / (268\text{ K}) - 1} = \mathbf{10.72}$$

Thus,

$$\dot{W}_{\text{in,min}} = \frac{\dot{Q}_L}{\text{COP}_{\text{max}}} = \frac{130\text{ W}}{10.72} = \mathbf{12.1\text{ W}}$$

11-98 A thermoelectric cooler that operates at specified conditions with a given COP is considered. The required power input to the thermoelectric cooler is to be determined.

Analysis The required power input is determined from the definition of COP_R,

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} \longrightarrow \dot{W}_{\text{in}} = \frac{\dot{Q}_L}{\text{COP}_R} = \frac{180 \text{ W}}{0.15} = \mathbf{1200 \text{ W}}$$

11-99E A thermoelectric cooler that operates at specified conditions with a given COP is considered. The rate of heat removal is to be determined.

Analysis The required power input is determined from the definition of COP_R,

$$\text{COP}_R = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} \longrightarrow \dot{Q}_L = \text{COP}_R \dot{W}_{\text{in}} = (0.18)(1.8 \text{ hp}) \left(\frac{42.41 \text{ Btu/min}}{1 \text{ hp}} \right) = \mathbf{13.7 \text{ Btu/min}}$$

11-100 A thermoelectric refrigerator powered by a car battery cools 9 canned drinks in 12 h. The average COP of this refrigerator is to be determined.

Assumptions Heat transfer through the walls of the refrigerator is negligible.

Properties The properties of canned drinks are the same as those of water at room temperature, $\rho = 1 \text{ kg/L}$ and $c_p = 4.18 \text{ kJ/kg}\cdot^\circ\text{C}$ (Table A-3).

Analysis The cooling rate of the refrigerator is simply the rate of decrease of the energy of the canned drinks,

$$\begin{aligned} m &= \rho V = 9 \times (1 \text{ kg/L})(0.350 \text{ L}) = 3.15 \text{ kg} \\ Q_{\text{cooling}} &= mc\Delta T = (3.15 \text{ kg})(4.18 \text{ kJ/kg}\cdot^\circ\text{C})(25 - 3)^\circ\text{C} = 290 \text{ kJ} \\ \dot{Q}_{\text{cooling}} &= \frac{Q_{\text{cooling}}}{\Delta t} = \frac{290 \text{ kJ}}{12 \times 3600 \text{ s}} = 0.00671 \text{ kW} = 6.71 \text{ W} \end{aligned}$$

The electric power consumed by the refrigerator is

$$\dot{W}_{\text{in}} = VI = (12 \text{ V})(3 \text{ A}) = 36 \text{ W}$$

Then the COP of the refrigerator becomes

$$\text{COP} = \frac{\dot{Q}_{\text{cooling}}}{\dot{W}_{\text{in}}} = \frac{6.71 \text{ W}}{36 \text{ W}} = \mathbf{0.186} \approx 0.20$$

11-101E A thermoelectric cooler is said to cool a 12-oz drink or to heat a cup of coffee in about 15 min. The average rate of heat removal from the drink, the average rate of heat supply to the coffee, and the electric power drawn from the battery of the car are to be determined.

Assumptions Heat transfer through the walls of the refrigerator is negligible.

Properties The properties of canned drinks are the same as those of water at room temperature, $c_p = 1.0 \text{ Btu/lbm}\cdot^\circ\text{F}$ (Table A-3E).

Analysis (a) The average cooling rate of the refrigerator is simply the rate of decrease of the energy content of the canned drinks,

$$Q_{\text{cooling}} = mc_p \Delta T = (0.771 \text{ lbm})(1.0 \text{ Btu/lbm}\cdot^\circ\text{F})(78 - 38)^\circ\text{F} = 30.84 \text{ Btu}$$

$$\dot{Q}_{\text{cooling}} = \frac{Q_{\text{cooling}}}{\Delta t} = \frac{30.84 \text{ Btu}}{15 \times 60 \text{ s}} \left(\frac{1055 \text{ J}}{1 \text{ Btu}} \right) = \mathbf{36.2 \text{ W}}$$

(b) The average heating rate of the refrigerator is simply the rate of increase of the energy content of the canned drinks,

$$Q_{\text{heating}} = mc_p \Delta T = (0.771 \text{ lbm})(1.0 \text{ Btu/lbm}\cdot^\circ\text{F})(130 - 75)^\circ\text{F} = 42.4 \text{ Btu}$$

$$\dot{Q}_{\text{heating}} = \frac{Q_{\text{heating}}}{\Delta t} = \frac{42.4 \text{ Btu}}{15 \times 60 \text{ s}} \left(\frac{1055 \text{ J}}{1 \text{ Btu}} \right) = \mathbf{49.7 \text{ W}}$$

(c) The electric power drawn from the car battery during cooling and heating is

$$\dot{W}_{\text{in,cooling}} = \frac{\dot{Q}_{\text{cooling}}}{\text{COP}_{\text{cooling}}} = \frac{36.2 \text{ W}}{0.2} = \mathbf{181 \text{ W}}$$

$$\text{COP}_{\text{heating}} = \text{COP}_{\text{cooling}} + 1 = 0.2 + 1 = 1.2$$

$$\dot{W}_{\text{in,heating}} = \frac{\dot{Q}_{\text{heating}}}{\text{COP}_{\text{heating}}} = \frac{49.7 \text{ W}}{1.2} = \mathbf{41.4 \text{ W}}$$

11-102 The maximum power a thermoelectric generator can produce is to be determined.

Analysis The maximum thermal efficiency this thermoelectric generator can have is

$$\eta_{\text{th,max}} = 1 - \frac{T_L}{T_H} = 1 - \frac{295 \text{ K}}{363 \text{ K}} = 0.1873$$

Thus,

$$\dot{W}_{\text{out,max}} = \eta_{\text{th,max}} \dot{Q}_{\text{in}} = (0.1873)(7 \times 10^6 \text{ kJ/h}) = 1.31 \times 10^6 \text{ kJ/h} = \mathbf{364 \text{ kW}}$$

Review Problems

11-103 A house is cooled adequately by a 3.5 ton air-conditioning unit. The rate of heat gain of the house when the air-conditioner is running continuously is to be determined.

Assumptions 1 The heat gain includes heat transfer through the walls and the roof, infiltration heat gain, solar heat gain, internal heat gain, etc. **2** Steady operating conditions exist.

Analysis Noting that 1 ton of refrigeration is equivalent to a cooling rate of 211 kJ/min, the rate of heat gain of the house in steady operation is simply equal to the cooling rate of the air-conditioning system,

$$\dot{Q}_{\text{heat gain}} = \dot{Q}_{\text{cooling}} = (3.5 \text{ ton})(211 \text{ kJ/min}) = 738.5 \text{ kJ/min} = \mathbf{44,310 \text{ kJ/h}}$$

11-104 A steady-flow Carnot refrigeration cycle with refrigerant-134a as the working fluid is considered. The COP, the condenser and evaporator pressures, and the net work input are to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis (a) The COP of this refrigeration cycle is determined from

$$\text{COP}_{\text{R,C}} = \frac{1}{(T_H/T_L) - 1} = \frac{1}{(303 \text{ K})/(253 \text{ K}) - 1} = \mathbf{5.060}$$

(b) The condenser and evaporative pressures are (Table A-11)

$$P_{\text{evap}} = P_{\text{sat}@-20^\circ\text{C}} = \mathbf{132.82 \text{ kPa}}$$

$$P_{\text{cond}} = P_{\text{sat}@30^\circ\text{C}} = \mathbf{770.64 \text{ kPa}}$$

(c) The net work input is determined from

$$h_1 = (h_f + x_1 h_{fg})_{@-20^\circ\text{C}} = 25.47 + (0.15)(212.96) = 57.42 \text{ kJ/kg}$$

$$h_2 = (h_f + x_2 h_{fg})_{@-20^\circ\text{C}} = 25.47 + (0.80)(212.96) = 195.84 \text{ kJ/kg}$$

$$q_L = h_2 - h_1 = 195.84 - 57.42 = 138.4 \text{ kJ/kg}$$

$$w_{\text{net,in}} = \frac{q_L}{\text{COP}_R} = \frac{138.4 \text{ kJ/kg}}{5.060} = \mathbf{27.36 \text{ kJ/kg}}$$

11-105 A heat pump water heater has a COP of 3.4 and consumes 6 kW when running. It is to be determined if this heat pump can be used to meet the cooling needs of a room by absorbing heat from it.

Assumptions The COP of the heat pump remains constant whether heat is absorbed from the outdoor air or room air.

Analysis The COP of the heat pump is given to be 3.4. Then the COP of the air-conditioning system becomes

$$\text{COP}_{\text{air-cond}} = \text{COP}_{\text{heat pump}} - 1 = 3.4 - 1 = 2.4$$

Then the rate of cooling (heat absorption from the air) becomes

$$\dot{Q}_{\text{cooling}} = \text{COP}_{\text{air-cond}} \dot{W}_{\text{in}} = (3.4)(6 \text{ kW}) = 20.4 \text{ kW} = 51,840 \text{ kJ/h}$$

since 1 kW = 3600 kJ/h. We conclude that this heat pump **can meet** the cooling needs of the room since its cooling rate is greater than the rate of heat gain of the room.

11-106 A heat pump that operates on the ideal vapor-compression cycle with refrigerant-134a as the working fluid is used to heat a house. The rate of heat supply to the house, the volume flow rate of the refrigerant at the compressor inlet, and the COP of this heat pump are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) In an ideal vapor-compression refrigeration cycle, the compression process is isentropic, the refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure. From the refrigerant tables (Tables A-12 and A-13),

$$P_1 = 320 \text{ kPa} \left. \begin{array}{l} h_1 = h_g @ 320 \text{ kPa} = 251.93 \text{ kJ/kg} \\ s_1 = s_g @ 320 \text{ kPa} = 0.93026 \text{ kJ/kg} \cdot \text{K} \\ \nu_1 = \nu_g @ 320 \text{ kPa} = 0.063681 \text{ m}^3/\text{kg} \end{array} \right\} \text{sat. vapor}$$

$$P_2 = 1.4 \text{ MPa} \left. \begin{array}{l} h_2 = 282.60 \text{ kJ/kg} \\ s_2 = s_1 \end{array} \right\}$$

$$P_3 = 1.4 \text{ MPa} \left. \begin{array}{l} h_3 = h_f @ 1.4 \text{ MPa} = 127.25 \text{ kJ/kg} \\ \text{sat. liquid} \end{array} \right\}$$

$$h_4 \cong h_3 = 127.25 \text{ kJ/kg} \text{ (throttling)}$$

The rate of heat supply to the house is determined from

$$\dot{Q}_H = \dot{m}(h_2 - h_3) = (0.25 \text{ kg/s})(282.60 - 127.25) \text{ kJ/kg} = \mathbf{38.8 \text{ kW}}$$

(b) The volume flow rate of the refrigerant at the compressor inlet is

$$\dot{V}_1 = \dot{m}\nu_1 = (0.25 \text{ kg/s})(0.063681 \text{ m}^3/\text{kg}) = \mathbf{0.0159 \text{ m}^3/\text{s}}$$

(c) The COP of this heat pump is determined from

$$\text{COP}_R = \frac{q_L}{w_{\text{in}}} = \frac{h_2 - h_3}{h_2 - h_1} = \frac{282.60 - 127.25}{282.60 - 251.93} = \mathbf{5.07}$$

11-107 A large refrigeration plant that operates on the ideal vapor-compression cycle with refrigerant-134a as the working fluid is considered. The mass flow rate of the refrigerant, the power input to the compressor, and the mass flow rate of the cooling water are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) In an ideal vapor-compression refrigeration cycle, the compression process is isentropic, the refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure. From the refrigerant tables (Tables A-12 and A-13),

$$\left. \begin{array}{l} P_1 = 120 \text{ kPa} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} h_1 = h_g @ 120 \text{ kPa} = 236.99 \text{ kJ/kg} \\ s_1 = s_g @ 120 \text{ kPa} = 0.94789 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_2 = 0.7 \text{ MPa} \\ s_2 = s_1 \end{array} \right\} \begin{array}{l} h_2 = 273.52 \text{ kJ/kg} \quad (T_2 = 34.95^\circ\text{C}) \end{array}$$

$$\left. \begin{array}{l} P_3 = 0.7 \text{ MPa} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 0.7 \text{ MPa} = 88.82 \text{ kJ/kg}$$

$$h_4 \cong h_3 = 88.82 \text{ kJ/kg} \quad (\text{throttling})$$

The mass flow rate of the refrigerant is determined from

$$\dot{m} = \frac{\dot{Q}_L}{h_1 - h_4} = \frac{100 \text{ kJ/s}}{(236.99 - 88.82) \text{ kJ/kg}} = \mathbf{0.6749 \text{ kg/s}}$$

(b) The power input to the compressor is

$$\dot{W}_{\text{in}} = \dot{m}(h_2 - h_1) = (0.6749 \text{ kg/s})(273.52 - 236.99) \text{ kJ/kg} = \mathbf{24.7 \text{ kW}}$$

(c) The mass flow rate of the cooling water is determined from

$$\dot{Q}_H = \dot{m}(h_2 - h_3) = (0.6749 \text{ kg/s})(273.52 - 88.82) \text{ kJ/kg} = 124.7 \text{ kW}$$

$$\dot{m}_{\text{cooling}} = \frac{\dot{Q}_H}{(c_p \Delta T)_{\text{water}}} = \frac{124.7 \text{ kJ/s}}{(4.18 \text{ kJ/kg} \cdot ^\circ\text{C})(8^\circ\text{C})} = \mathbf{3.73 \text{ kg/s}}$$

11-108 Problem 11-107 is reconsidered. The effect of evaporator pressure on the COP and the power input is to be investigated.

Analysis The problem is solved using EES, and the solution is given below.

11-109 A large refrigeration plant operates on the vapor-compression cycle with refrigerant-134a as the working fluid. The mass flow rate of the refrigerant, the power input to the compressor, the mass flow rate of the cooling water, and the rate of exergy destruction associated with the compression process are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) The refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure. From the refrigerant tables (Tables A-12 and A-13),

$$\left. \begin{array}{l} P_1 = 120 \text{ kPa} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} h_1 = h_g @ 120 \text{ kPa} = 236.99 \text{ kJ/kg} \\ s_1 = s_g @ 120 \text{ kPa} = 0.94789 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_2 = 0.7 \text{ MPa} \\ s_2 = s_1 \end{array} \right\} \begin{array}{l} h_{2s} = 273.52 \text{ kJ/kg} \quad (T_2 = 34.95^\circ\text{C}) \\ \end{array}$$

$$\left. \begin{array}{l} P_3 = 0.7 \text{ MPa} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 0.7 \text{ MPa} = 88.82 \text{ kJ/kg}$$

$$h_4 \cong h_3 = 88.82 \text{ kJ/kg} \quad (\text{throttling})$$

The mass flow rate of the refrigerant is determined from

$$\dot{m} = \frac{\dot{Q}_L}{h_1 - h_4} = \frac{100 \text{ kJ/s}}{(236.99 - 88.82) \text{ kJ/kg}} = \mathbf{0.6749 \text{ kg/s}}$$

(b) The actual enthalpy at the compressor exit is

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} \longrightarrow h_2 = h_1 + (h_{2s} - h_1) / \eta_C = 236.99 + (273.52 - 236.99) / (0.75) = 285.70 \text{ kJ/kg}$$

Thus,

$$\dot{W}_{\text{in}} = \dot{m}(h_2 - h_1) = (0.6749 \text{ kg/s})(285.70 - 236.99) \text{ kJ/kg} = \mathbf{32.9 \text{ kW}}$$

(c) The mass flow rate of the cooling water is determined from

$$\dot{Q}_H = \dot{m}(h_2 - h_3) = (0.6749 \text{ kg/s})(285.70 - 88.82) \text{ kJ/kg} = 132.9 \text{ kW}$$

and

$$\dot{m}_{\text{cooling}} = \frac{\dot{Q}_H}{(c_p \Delta T)_{\text{water}}} = \frac{132.9 \text{ kJ/s}}{(4.18 \text{ kJ/kg} \cdot ^\circ\text{C})(8^\circ\text{C})} = \mathbf{3.97 \text{ kg/s}}$$

The exergy destruction associated with this adiabatic compression process is determined from

$$\dot{X}_{\text{destroyed}} = T_0 \dot{S}_{\text{gen}} = T_0 \dot{m}(s_2 - s_1)$$

where

$$\left. \begin{array}{l} P_2 = 0.7 \text{ MPa} \\ h_2 = 285.70 \text{ kJ/kg} \end{array} \right\} s_2 = 0.98665 \text{ kJ/kg} \cdot \text{K}$$

Thus,

$$\dot{X}_{\text{destroyed}} = (298 \text{ K})(0.6749 \text{ kg/s})(0.98665 - 0.94789) \text{ kJ/kg} \cdot \text{K} = \mathbf{7.80 \text{ kW}}$$

11-110 An ideal vapor-compression refrigeration cycle with refrigerant-22 as the working fluid is considered. The evaporator is located inside the air handler of building. The hardware and the T-s diagram for this heat pump application are to be sketched. The COP of the unit and the ratio of volume flow rate of air entering the air handler to mass flow rate of R-22 through the air handler are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) In an ideal vapor-compression refrigeration cycle, the compression process is isentropic, the refrigerant enters the compressor as a saturated vapor at the evaporator pressure, and leaves the condenser as saturated liquid at the condenser pressure. From the refrigerant-22 data from the problem statement,

$$\left. \begin{array}{l} T_1 = -5^\circ\text{C} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} h_1 = h_g @ -5^\circ\text{C} = 248.1 \text{ kJ/kg} \\ s_1 = s_g @ -5^\circ\text{C} = 0.9344 \text{ kJ/kg}\cdot\text{K} \end{array}$$

$$\left. \begin{array}{l} P_2 = 1728 \text{ kPa} \\ s_2 = s_1 \end{array} \right\} h_2 = 283.7 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 1728 \text{ kPa} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 1728 \text{ kPa} = 101 \text{ kJ/kg}$$

$$h_4 \cong h_3 = 101 \text{ kJ/kg} \quad (\text{throttling})$$

(b) The COP of the refrigerator is determined from its definition,

$$\text{COP}_R = \frac{q_L}{w_{\text{in}}} = \frac{h_1 - h_4}{h_2 - h_1} = \frac{248.1 - 101}{283.7 - 248.1} = \mathbf{4.13}$$

(c) An energy balance on the evaporator gives

$$\dot{Q}_L = \dot{m}_R (h_1 - h_4) = \dot{m}_a c_p \Delta T = \frac{\dot{V}_a}{\nu_a} c_p \Delta T$$

Rearranging, we obtain the ratio of volume flow rate of air entering the air handler to mass flow rate of R-22 through the air handler

$$\begin{aligned} \frac{\dot{V}_a}{\dot{m}_R} &= \frac{h_1 - h_4}{(1/\nu)c_p \Delta T} = \frac{(248.1 - 101) \text{ kJ/kg}}{(1/0.8323 \text{ m}^3/\text{kg})(1.005 \text{ kJ/kg}\cdot\text{K})(20 \text{ K})} \\ &= 6.091 \text{ (m}^3 \text{ air/s)/(kg R22/s)} \\ &= \mathbf{365 \text{ (m}^3 \text{ air/min)/(kg R22/s)}} \end{aligned}$$

Note that the specific volume of air is obtained from ideal gas equation taking the pressure of air to be 100 kPa (given) and using the average temperature of air ($17^\circ\text{C} = 290 \text{ K}$) to be $0.8323 \text{ m}^3/\text{kg}$.

11-111 An air-conditioner with refrigerant-134a as the refrigerant is considered. The temperature of the refrigerant at the compressor exit, the rate of heat generated by the people in the room, the COP of the air-conditioner, and the minimum volume flow rate of the refrigerant at the compressor inlet are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) From the refrigerant-134a tables (Tables A-11 through A-13)

$$P_1 = 500 \text{ kPa} \left\{ \begin{array}{l} h_1 = 259.36 \text{ kJ/kg} \\ v_1 = 0.04117 \text{ m}^3/\text{kg} \\ s_1 = 0.9242 \text{ kJ/kg} \end{array} \right.$$

$$P_2 = 1200 \text{ kPa} \left\{ \begin{array}{l} h_{2s} = 277.45 \\ s_2 = s_1 \end{array} \right.$$

$$h_3 = h_{f@1200\text{kPa}} = 117.79 \text{ kJ/kg}$$

$$h_4 = h_3 = 117.79 \text{ kJ/kg}$$

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1}$$

$$0.75 = \frac{277.45 - 259.36}{h_2 - 259.36} \rightarrow h_2 = 283.48 \text{ kJ/kg}$$

$$P_2 = 1200 \text{ kPa} \left\{ \begin{array}{l} h_2 = 283.48 \text{ kJ/kg} \\ T_2 = \mathbf{54.5^\circ\text{C}} \end{array} \right.$$

(b) The mass flow rate of the refrigerant is

$$\dot{m} = \frac{\dot{v}_1}{v_1} = \frac{(100 \text{ L/min}) \left(\frac{1 \text{ m}^3}{1000 \text{ L}} \right) \left(\frac{1 \text{ min}}{60 \text{ s}} \right)}{0.04117 \text{ m}^3/\text{kg}} = 0.04048 \text{ kg/s}$$

The refrigeration load is

$$\dot{Q}_L = \dot{m}(h_1 - h_4) = (0.04048 \text{ kg/s})(259.36 - 117.79) \text{ kJ/kg} = 5.731 \text{ kW}$$

which is the total heat removed from the room. Then, the rate of heat generated by the people in the room is determined from

$$\dot{Q}_{\text{people}} = \dot{Q}_L - \dot{Q}_{\text{heat}} - \dot{Q}_{\text{equip}} = (5.731 - 250/60 - 0.9) \text{ kW} = \mathbf{0.665 \text{ kW}}$$

(c) The power input and the COP are

$$\dot{W}_{\text{in}} = \dot{m}(h_2 - h_1) = (0.04048 \text{ kg/s})(283.48 - 259.36) \text{ kJ/kg} = 0.9764 \text{ kW}$$

$$\text{COP} = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} = \frac{5.731}{0.9764} = \mathbf{5.87}$$

(d) The reversible COP of the cycle is

$$\text{COP}_{\text{rev}} = \frac{1}{T_H / T_L - 1} = \frac{1}{(34 + 273) / (26 + 273) - 1} = 37.38$$

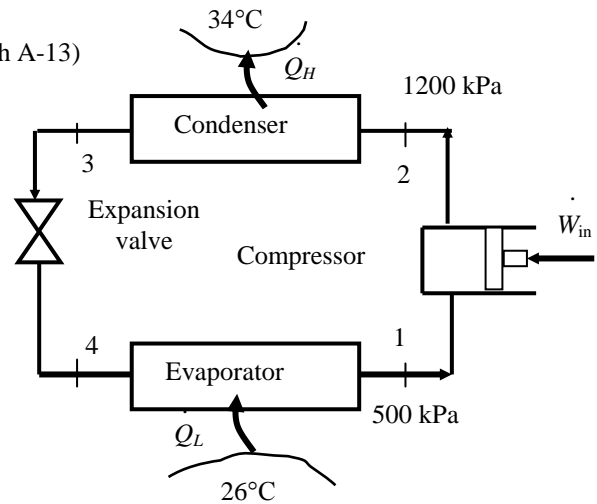

The corresponding minimum power input is

$$\dot{W}_{\text{in,min}} = \frac{\dot{Q}_L}{\text{COP}_{\text{rev}}} = \frac{5.731 \text{ kW}}{37.38} = 0.1533 \text{ kW}$$

The minimum mass and volume flow rates are

$$\dot{m}_{\text{min}} = \frac{\dot{W}_{\text{in,min}}}{h_2 - h_1} = \frac{0.1533 \text{ kW}}{(283.48 - 259.36) \text{ kJ/kg}} = 0.006358 \text{ kg/s}$$

$$\dot{v}_{1,\text{min}} = \dot{m}_{\text{min}} v_1 = (0.006358 \text{ kg/s})(0.04117 \text{ m}^3/\text{kg}) = (0.0002618 \text{ m}^3/\text{s}) = \mathbf{15.7 \text{ L/min}}$$

11-112 An air conditioner operates on the vapor-compression refrigeration cycle. The rate of cooling provided to the space, the COP, the isentropic efficiency and the exergetic efficiency of the compressor, the exergy destruction in each component of the cycle, the total exergy destruction, the minimum power input, and the second-law efficiency of the cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) The properties of R-134a are (Tables A-11 through A-13)

$$T_{\text{sat}@180\text{kPa}} = -12.7^\circ\text{C}$$

$$\left. \begin{array}{l} P_1 = 180 \text{ kPa} \\ T_1 = -12.7 + 2.7 = 10^\circ\text{C} \end{array} \right\} \begin{array}{l} h_1 = 245.15 \text{ kJ/kg} \\ s_1 = 0.9484 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_2 = 1200 \text{ kPa} \\ s_1 = s_1 \end{array} \right\} h_{2s} = 285.34 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_2 = 1200 \text{ kPa} \\ T_2 = 60^\circ\text{C} \end{array} \right\} \begin{array}{l} h_2 = 289.66 \text{ kJ/kg} \\ s_2 = 0.9615 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$T_{\text{sat}@1200\text{kPa}} = 46.3^\circ\text{C}$$

$$\left. \begin{array}{l} P_3 = 1200 \text{ kPa} \\ T_3 = 46.3 - 6.3 = 40^\circ\text{C} \end{array} \right\} \begin{array}{l} h_3 \cong h_{f@40^\circ\text{C}} = 108.27 \text{ kJ/kg} \\ s_3 \cong s_{f@40^\circ\text{C}} = 0.3949 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$h_4 = h_3 = 108.27 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_4 = 180 \text{ kPa} \\ h_4 = 108.26 \text{ kJ/kg} \end{array} \right\} s_4 = 0.4229 \text{ kJ/kg} \cdot \text{K}$$

The cooling load and the COP are

$$\begin{aligned} \dot{Q}_L &= \dot{m}(h_1 - h_4) = (0.06 \text{ kg/s})(245.15 - 108.27) \text{ kJ/kg} = 8.213 \text{ kW} \\ &= (8.213 \text{ kW}) \left(\frac{3412 \text{ Btu/h}}{1 \text{ kW}} \right) = \mathbf{28,020 \text{ Btu/h}} \end{aligned}$$

$$\dot{Q}_H = \dot{m}(h_2 - h_3) = (0.06 \text{ kg/s})(289.66 - 108.27) \text{ kJ/kg} = 10.88 \text{ kW}$$

$$\dot{W}_{\text{in}} = \dot{m}(h_2 - h_1) = (0.06 \text{ kg/s})(289.66 - 245.15) \text{ kJ/kg} = 2.670 \text{ kW}$$

$$\text{COP} = \frac{\dot{Q}_L}{\dot{W}_{\text{in}}} = \frac{8.213 \text{ kW}}{2.670 \text{ kW}} = \mathbf{3.076}$$

(b) The isentropic efficiency of the compressor is

$$\eta_C = \frac{h_{2s} - h_1}{h_2 - h_1} = \frac{285.34 - 245.15}{289.66 - 245.15} = 0.903 = \mathbf{90.3\%}$$

The reversible power and the exergetic efficiency for the compressor are

$$\begin{aligned} \dot{W}_{\text{rev}} &= \dot{m}[(h_2 - h_1) - T_0(s_2 - s_1)] \\ &= (0.06 \text{ kg/s})[(289.66 - 245.15) \text{ kJ/kg} - (310 \text{ K})(0.9615 - 0.9484) \text{ kJ/kg} \cdot \text{K}] \\ &= 2.428 \text{ kW} \end{aligned}$$

$$\eta_{\text{ex,C}} = \frac{\dot{W}_{\text{rev}}}{\dot{W}_{\text{in}}} = \frac{2.428 \text{ kW}}{2.670 \text{ kW}} = 0.909 = \mathbf{90.9\%}$$

(c) The exergy destruction in each component of the cycle is determined as follows

Compressor:

$$\dot{S}_{\text{gen},1-2} = \dot{m}(s_2 - s_1) = (0.06 \text{ kg/s})(0.9615 - 0.9484) \text{ kJ/kg} \cdot \text{K} = 0.0007827 \text{ kW/K}$$

$$\dot{E}x_{\text{dest},1,2} = T_0 \dot{S}_{\text{gen},1,2} = (310 \text{ K})(0.0007827 \text{ kW/K}) = \mathbf{0.2426 \text{ kW}}$$

Condenser:

$$\dot{S}_{\text{gen},2-3} = \dot{m}(s_3 - s_2) + \frac{\dot{Q}_H}{T_H} = (0.06 \text{ kg/s})(0.3949 - 0.9615) \text{ kJ/kg} \cdot \text{K} + \frac{10.88 \text{ kW}}{310 \text{ K}} = 0.001114 \text{ kW/K}$$

$$\dot{E}x_{\text{dest},2,3} = T_0 \dot{S}_{\text{gen},2,3} = (310 \text{ K})(0.001114 \text{ kJ/kg} \cdot \text{K}) = \mathbf{0.3452 \text{ kW}}$$

Expansion valve:

$$\dot{S}_{\text{gen},3-4} = \dot{m}(s_4 - s_3) = (0.06 \text{ kg/s})(0.4229 - 0.3949) \text{ kJ/kg} \cdot \text{K} = 0.001678 \text{ kW/K}$$

$$\dot{E}x_{\text{dest},3,4} = T_0 \dot{S}_{\text{gen},3,4} = (310 \text{ K})(0.001678 \text{ kJ/kg} \cdot \text{K}) = \mathbf{0.5202 \text{ kJ/kg}}$$

Evaporator:

$$\dot{S}_{\text{gen},4-1} = \dot{m}(s_1 - s_4) - \frac{\dot{Q}_L}{T_L} = (0.06 \text{ kg/s})(0.9484 - 0.4229) \text{ kJ/kg} \cdot \text{K} - \frac{8.213 \text{ kW}}{294 \text{ K}} = 0.003597 \text{ kW/K}$$

$$\dot{E}x_{\text{dest},4,1} = T_0 \dot{S}_{\text{gen},4,1} = (310 \text{ K})(0.003597 \text{ kJ/kg} \cdot \text{K}) = \mathbf{1.115 \text{ kW}}$$

The total exergy destruction can be determined by adding exergy destructions in each component:

$$\begin{aligned} \dot{E}x_{\text{dest},\text{total}} &= \dot{E}x_{\text{dest},1,2} + \dot{E}x_{\text{dest},2,3} + \dot{E}x_{\text{dest},3,4} + \dot{E}x_{\text{dest},4,1} \\ &= 0.2426 + 0.3452 + 0.5202 + 1.115 \\ &= \mathbf{2.223 \text{ kW}} \end{aligned}$$

(d) The exergy of the heat transferred from the low-temperature medium is

$$\dot{E}x_{\dot{Q}_L} = -\dot{Q}_L \left(1 - \frac{T_0}{T_L} \right) = -(8.213 \text{ kW}) \left(1 - \frac{310}{294} \right) = 0.4470 \text{ kW}$$

This is the minimum power input to the cycle:

$$\dot{W}_{\text{in},\text{min}} = \dot{E}x_{\dot{Q}_L} = \mathbf{0.4470 \text{ kW}}$$

The second-law efficiency of the cycle is

$$\eta_{\text{II}} = \frac{\dot{W}_{\text{in},\text{min}}}{\dot{W}_{\text{in}}} = \frac{0.4470}{2.670} = 0.167 = \mathbf{16.7\%}$$

The total exergy destruction in the cycle can also be determined from

$$\dot{E}x_{\text{dest},\text{total}} = \dot{W}_{\text{in}} - \dot{E}x_{\dot{Q}_L} = 2.670 - 0.4470 = 2.223 \text{ kW}$$

The result is the same as expected.

11-113 A two-stage compression refrigeration system using refrigerant-134a as the working fluid is considered. The fraction of the refrigerant that evaporates as it is throttled to the flash chamber, the amount of heat removed from the refrigerated space, the compressor work, and the COP are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible. 3 The flashing chamber is adiabatic.

Analysis (a) The enthalpies of the refrigerant at several states are determined from the refrigerant tables to be (Tables A-11, A-12, and A-13)

$$h_1 = 236.99 \text{ kJ/kg}, \quad h_2 = 266.29 \text{ kJ/kg}$$

$$h_3 = 259.36 \text{ kJ/kg},$$

$$h_5 = 127.25 \text{ kJ/kg}, \quad h_6 = 127.25 \text{ kJ/kg}$$

$$h_7 = 73.32 \text{ kJ/kg}, \quad h_8 = 73.32 \text{ kJ/kg}$$

The fraction of the refrigerant that evaporates as it is throttled to the flash chamber is simply the quality at state 6,

$$x_6 = \frac{h_6 - h_f}{h_{fg}} = \frac{127.25 - 73.32}{186.04} = \mathbf{0.2899}$$

(b) The enthalpy at state 9 is determined from an energy balance on the mixing chamber:

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\phi=0(\text{steady})}{=} 0 \rightarrow \dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_e h_e = \sum \dot{m}_i h_i$$

$$(1)h_9 = x_6 h_3 + (1 - x_6)h_2$$

$$h_9 = (0.2899)(259.36) + (1 - 0.2899)(266.29) = 264.28 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_9 = 0.5 \text{ MPa} \\ h_9 = 264.28 \text{ kJ/kg} \end{array} \right\} s_9 = 0.94108 \text{ kJ/kg} \cdot \text{K}$$

Also,

$$\left. \begin{array}{l} P_4 = 1.4 \text{ MPa} \\ s_4 = s_9 = 0.94108 \text{ kJ/kg} \cdot \text{K} \end{array} \right\} h_4 = 286.19 \text{ kJ/kg}$$

Then the amount of heat removed from the refrigerated space and the compressor work input per unit mass of refrigerant flowing through the condenser are

$$q_L = (1 - x_6)(h_1 - h_8) = (1 - 0.2899)(236.99 - 73.32) \text{ kJ/kg} = \mathbf{116.2 \text{ kJ/kg}}$$

$$\begin{aligned} w_{\text{in}} &= w_{\text{compI, in}} + w_{\text{compII, in}} = (1 - x_6)(h_2 - h_1) + (1)(h_4 - h_9) \\ &= (1 - 0.2899)(266.29 - 236.99) \text{ kJ/kg} + (1)(286.19 - 264.28) \text{ kJ/kg} \\ &= \mathbf{42.72 \text{ kJ/kg}} \end{aligned}$$

(c) The coefficient of performance is determined from

$$\text{COP}_R = \frac{q_L}{w_{\text{in}}} = \frac{116.2 \text{ kJ/kg}}{42.72 \text{ kJ/kg}} = \mathbf{2.72}$$

11-114E A two-evaporator compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The cooling load of both evaporators per unit of flow through the compressor and the COP of the system are to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis From the refrigerant tables (Tables A-11E, A-12E, and A-13E),

$$\left. \begin{array}{l} P_3 = 160 \text{ psia} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 160 \text{ psia} = 48.527 \text{ Btu/lbm}$$

$$h_4 = h_6 \cong h_3 = 48.527 \text{ Btu/lbm} \quad (\text{throttling})$$

$$\left. \begin{array}{l} T_5 = 30^\circ\text{F} \\ \text{sat. vapor} \end{array} \right\} h_5 = h_g @ 30^\circ\text{F} = 107.42 \text{ Btu/lbm}$$

$$\left. \begin{array}{l} T_7 = -29.5^\circ\text{F} \\ \text{sat. vapor} \end{array} \right\} h_7 = h_g @ -29.5^\circ\text{F} = 98.69 \text{ Btu/lbm}$$

For a unit mass flowing through the compressor, the fraction of mass flowing through Evaporator II is denoted by x and that through Evaporator I is y ($y = 1 - x$). From the cooling loads specification,

$$\begin{aligned} \dot{Q}_{L, \text{evap1}} &= 2\dot{Q}_{L, \text{evap2}} \\ x(h_5 - h_4) &= 2y(h_7 - h_6) \end{aligned}$$

where $x = 1 - y$

Combining these results and solving for y gives

$$y = \frac{h_5 - h_4}{2(h_7 - h_6) + (h_5 - h_4)} = \frac{107.42 - 48.527}{2(98.69 - 48.527) + (107.42 - 48.527)} = 0.3699$$

Then, $x = 1 - y = 1 - 0.3699 = 0.6301$

Applying an energy balance to the point in the system where the two evaporator streams are recombined gives

$$xh_5 + yh_7 = h_1 \longrightarrow h_1 = \frac{xh_5 + yh_7}{1} = \frac{(0.6301)(107.42) + (0.3699)(98.69)}{1} = 104.19 \text{ Btu/lbm}$$

Then,

$$\left. \begin{array}{l} P_1 = P_{\text{sat}} @ -29.5^\circ\text{F} \cong 10 \text{ psia} \\ h_1 = 104.19 \text{ Btu/lbm} \end{array} \right\} s_1 = 0.2418 \text{ Btu/lbm} \cdot \text{R}$$

$$\left. \begin{array}{l} P_2 = 160 \text{ psia} \\ s_2 = s_1 \end{array} \right\} h_2 = 131.15 \text{ Btu/lbm}$$

The cooling load of both evaporators per unit mass through the compressor is

$$\begin{aligned} q_L &= x(h_5 - h_4) + y(h_7 - h_6) \\ &= (0.6301)(107.42 - 48.527) \text{ Btu/lbm} + (0.3699)(98.69 - 48.527) \text{ Btu/lbm} \\ &= \mathbf{55.66 \text{ Btu/lbm}} \end{aligned}$$

The work input to the compressor is

$$w_{\text{in}} = h_2 - h_1 = (131.15 - 104.19) \text{ Btu/lbm} = 26.96 \text{ Btu/lbm}$$

The COP of this refrigeration system is determined from its definition,

$$\text{COP}_R = \frac{q_L}{w_{\text{in}}} = \frac{55.66 \text{ Btu/lbm}}{26.96 \text{ Btu/lbm}} = \mathbf{2.07}$$

11-115E A two-evaporator compression refrigeration cycle with refrigerant-134a as the working fluid is considered. The process with the greatest exergy destruction is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From Prob. 11-114E and the refrigerant tables (Tables A-11E, A-12E, and A-13E),

$$\begin{aligned} s_1 &= s_2 = 0.2418 \text{ Btu/lbm} \cdot \text{R} \\ s_3 &= 0.09776 \text{ Btu/lbm} \cdot \text{R} \\ s_4 &= 0.1024 \text{ Btu/lbm} \cdot \text{R} \\ s_5 &= 0.2226 \text{ Btu/lbm} \cdot \text{R} \\ s_6 &= 0.1129 \text{ Btu/lbm} \cdot \text{R} \\ s_7 &= 0.2295 \text{ Btu/lbm} \cdot \text{R} \\ x &= 0.6301 \\ y &= 1 - x = 0.3699 \\ q_{L,45} &= h_5 - h_4 = 58.89 \text{ Btu/lbm} \\ q_{L,67} &= h_7 - h_6 = 50.16 \text{ Btu/lbm} \\ q_H &= 82.62 \text{ Btu/lbm} \end{aligned}$$

The exergy destruction during a process of a stream from an inlet state to exit state is given by

$$x_{\text{dest}} = T_0 s_{\text{gen}} = T_0 \left(s_e - s_i - \frac{q_{\text{in}}}{T_{\text{source}}} + \frac{q_{\text{out}}}{T_{\text{sink}}} \right)$$

Application of this equation for each process of the cycle gives the exergy destructions per unit mass flowing through the compressor:

$$x_{\text{destroyed},23} = T_0 \left(s_3 - s_2 + \frac{q_H}{T_H} \right) = (540 \text{ R}) \left(0.09776 - 0.2418 + \frac{82.62 \text{ Btu/lbm}}{540 \text{ R}} \right) = 4.82 \text{ Btu/lbm}$$

$$\begin{aligned} x_{\text{destroyed},346} &= T_0 (xs_4 + ys_6 - s_3) \\ &= (540 \text{ R})(0.6301 \times 0.1024 + 0.3699 \times 0.1129 - 0.09776) \text{ Btu/lbm} \cdot \text{R} \\ &= 4.60 \text{ Btu/lbm} \end{aligned}$$

$$\begin{aligned} x_{\text{destroyed},45} &= xT_0 \left(s_5 - s_4 - \frac{q_{L,45}}{T_L} \right) \\ &= (0.6301)(540 \text{ R}) \left(0.2226 - 0.1024 - \frac{58.89 \text{ Btu/lbm}}{500 \text{ R}} \right) \\ &= 0.84 \text{ Btu/lbm} \end{aligned}$$

$$\begin{aligned} x_{\text{destroyed},67} &= yT_0 \left(s_7 - s_6 - \frac{q_{L,67}}{T_L} \right) \\ &= (0.3699)(540 \text{ R}) \left(0.2295 - 0.1129 - \frac{50.16 \text{ Btu/lbm}}{445 \text{ R}} \right) \\ &= 0.77 \text{ Btu/lbm} \end{aligned}$$

$$\begin{aligned} \dot{X}_{\text{destroyed,mixing}} &= T_0 (s_1 - xs_5 - ys_7) \\ &= (540 \text{ R}) [0.2418 - (0.6301)(0.2226) - (0.3699)(0.2295)] \\ &= \mathbf{9.00 \text{ Btu/lbm}} \end{aligned}$$

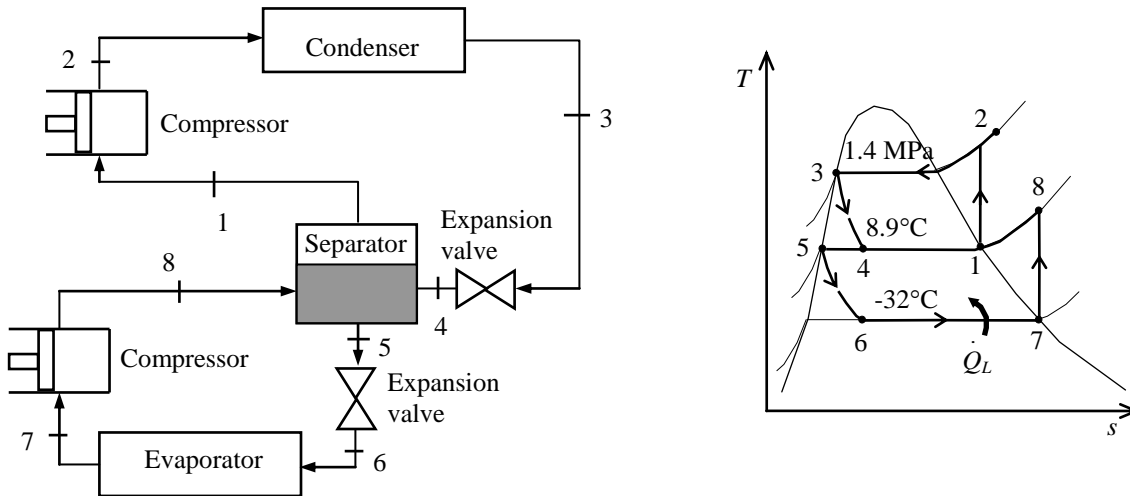

For isentropic processes, the exergy destruction is zero:

$$\dot{X}_{\text{destroyed},12} = 0$$

The greatest exergy destruction occurs during the mixing process. Note that heat is absorbed in evaporator 2 from a reservoir at -15°F (445 R), in evaporator 1 from a reservoir at 40°F (500 R), and rejected to a reservoir at 80°F (540 R), which is also taken as the dead state temperature.

11-116 A two-stage compression refrigeration system with a separation unit is considered. The rate of cooling and the power requirement are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the refrigerant tables (Tables A-11, A-12, and A-13),

$$\left. \begin{array}{l} T_1 = 8.9^\circ\text{C} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} h_1 = h_g @ 8.9^\circ\text{C} = 255.60 \text{ kJ/kg} \\ s_1 = s_g @ 8.9^\circ\text{C} = 0.92711 \text{ kJ/kg}\cdot\text{K} \end{array}$$

$$\left. \begin{array}{l} P_2 = 1400 \text{ kPa} \\ s_2 = s_1 \end{array} \right\} h_2 = 281.56 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 1400 \text{ kPa} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 1400 \text{ kPa} = 127.25 \text{ kJ/kg}$$

$$h_4 \cong h_3 = 127.25 \text{ kJ/kg} \quad (\text{throttling})$$

$$\left. \begin{array}{l} T_5 = 8.9^\circ\text{C} \\ \text{sat. liquid} \end{array} \right\} h_5 = h_f @ 8.9^\circ\text{C} = 63.91 \text{ kJ/kg}$$

$$h_6 \cong h_5 = 63.91 \text{ kJ/kg} \quad (\text{throttling})$$

$$\left. \begin{array}{l} T_7 = -32^\circ\text{C} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} h_7 = h_g @ -32^\circ\text{C} = 230.93 \text{ kJ/kg} \\ s_7 = s_g @ -32^\circ\text{C} = 0.95819 \text{ kJ/kg}\cdot\text{K} \end{array}$$

$$\left. \begin{array}{l} P_8 = P_{\text{sat}} @ 8.9^\circ\text{C} = 400 \text{ kPa} \\ s_8 = s_7 \end{array} \right\} h_8 = 264.51 \text{ kJ/kg}$$

An energy balance on the separator gives

$$\dot{m}_6(h_8 - h_5) = \dot{m}_2(h_1 - h_4) \longrightarrow \dot{m}_6 = \dot{m}_2 \frac{h_1 - h_4}{h_8 - h_5} = (2 \text{ kg/s}) \frac{255.60 - 127.25}{264.51 - 63.91} = 1.280 \text{ kg/s}$$

The rate of cooling produced by this system is then

$$\dot{Q}_L = \dot{m}_6(h_7 - h_6) = (1.280 \text{ kg/s})(230.93 - 63.91) \text{ kJ/kg} = \mathbf{213.7 \text{ kJ/s}}$$

The total power input to the compressors is

$$\begin{aligned} \dot{W}_{\text{in}} &= \dot{m}_6(h_8 - h_7) + \dot{m}_2(h_2 - h_1) \\ &= (1.280 \text{ kg/s})(264.51 - 230.93) \text{ kJ/kg} + (2 \text{ kg/s})(281.56 - 255.60) \text{ kJ/kg} \\ &= \mathbf{94.9 \text{ kW}} \end{aligned}$$

11-117 A two-stage vapor-compression refrigeration system with refrigerant-134a as the working fluid is considered. The process with the greatest exergy destruction is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From Prob. 11-116 and the refrigerant tables (Tables A-11, A-12, and A-13),

$$s_1 = s_2 = 0.92711 \text{ kJ/kg} \cdot \text{K}$$

$$s_3 = 0.45325 \text{ kJ/kg} \cdot \text{K}$$

$$s_4 = 0.47207 \text{ kJ/kg} \cdot \text{K}$$

$$s_5 = 0.24752 \text{ kJ/kg} \cdot \text{K}$$

$$s_6 = 0.26564 \text{ kJ/kg} \cdot \text{K}$$

$$s_7 = s_8 = 0.95819 \text{ kJ/kg} \cdot \text{K}$$

$$\dot{m}_{\text{upper}} = 2 \text{ kg/s}$$

$$\dot{m}_{\text{lower}} = 1.280 \text{ kg/s}$$

$$q_L = h_7 - h_6 = 167.02 \text{ kJ/kg}$$

$$q_H = h_2 - h_3 = 154.31 \text{ kJ/kg}$$

$$T_L = -22 + 273 = 251 \text{ K}$$

$$T_H = T_0 = 20 + 273 = 293 \text{ K}$$

The exergy destruction during a process of a stream from an inlet state to exit state is given by

$$x_{\text{dest}} = T_0 s_{\text{gen}} = T_0 \left(s_e - s_i - \frac{q_{\text{in}}}{T_{\text{source}}} + \frac{q_{\text{out}}}{T_{\text{sink}}} \right)$$

Application of this equation for each process of the cycle gives

$$\begin{aligned} \dot{X}_{\text{destroyed},23} &= \dot{m}_{\text{upper}} T_0 \left(s_3 - s_2 + \frac{q_H}{T_H} \right) \\ &= (2 \text{ kg/s})(298 \text{ K}) \left(0.45325 - 0.92711 + \frac{154.31 \text{ kJ/kg}}{293 \text{ K}} \right) \\ &= \mathbf{30.94 \text{ kW}} \end{aligned}$$

$$\dot{X}_{\text{destroyed},34} = \dot{m}_{\text{upper}} T_0 (s_4 - s_3) = (2 \text{ kg/s})(293 \text{ K})(0.47207 - 0.45325) \text{ kJ/kg} \cdot \text{K} = 11.03 \text{ kW}$$

$$\dot{X}_{\text{destroyed},56} = \dot{m}_{\text{lower}} T_0 (s_6 - s_5) = (1.280 \text{ kg/s})(293 \text{ K})(0.26564 - 0.24752) \text{ kJ/kg} \cdot \text{K} = 6.793 \text{ kW}$$

$$\begin{aligned} \dot{X}_{\text{destroyed},67} &= \dot{m}_{\text{lower}} T_0 \left(s_7 - s_6 - \frac{q_L}{T_L} \right) \\ &= (1.280 \text{ kg/s})(293 \text{ K}) \left(0.95819 - 0.26564 - \frac{167.02 \text{ kJ/kg}}{251 \text{ K}} \right) \\ &= 10.18 \text{ kW} \end{aligned}$$

$$\begin{aligned} \dot{X}_{\text{destroyed,separator}} &= T_0 [\dot{m}_{\text{lower}} (s_5 - s_8) + \dot{m}_{\text{upper}} (s_1 - s_4)] \\ &= (293 \text{ K}) [(1.280 \text{ kg/s})(0.24752 - 0.95819) + (2 \text{ kg/s})(0.92711 - 0.47207)] \\ &= 0.197 \text{ kW} \end{aligned}$$

For isentropic processes, the exergy destruction is zero:

$$\dot{X}_{\text{destroyed},12} = 0$$

$$\dot{X}_{\text{destroyed},78} = 0$$

Note that heat is absorbed from a reservoir at -22°C (251 K) and rejected to the standard ambient air at 20°C (293 K), which is also taken as the dead state temperature. The greatest exergy destruction occurs during the condensation process.

11-118 An aircraft on the ground is to be cooled by a gas refrigeration cycle operating with air on an open cycle. The temperature of the air leaving the turbine is to be determined.

Assumptions **1** Steady operating conditions exist. **2** Air is an ideal gas with constant specific heats at room temperature. **3** Kinetic and potential energy changes are negligible.

Properties The specific heat ratio of air at room temperature is $k = 1.4$ (Table A-2).

Analysis Assuming the turbine to be isentropic, the air temperature at the turbine exit is determined from

$$T_4 = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = (343 \text{ K}) \left(\frac{100 \text{ kPa}}{250 \text{ kPa}} \right)^{0.4/1.4} = 264 \text{ K} = -9.0^\circ\text{C}$$

11-119 A regenerative gas refrigeration cycle with helium as the working fluid is considered. The temperature of the helium at the turbine inlet, the COP of the cycle, and the net power input required are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Helium is an ideal gas with constant specific heats at room temperature. 3 Kinetic and potential energy changes are negligible.

Properties The properties of helium are $c_p = 5.1926 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.667$ (Table A-2).

Analysis (a) The temperature of the helium at the turbine inlet is determined from an energy balance on the regenerator,

$$\begin{aligned}\dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta\dot{E}_{\text{system}} \stackrel{\phi^0(\text{steady})}{=} 0 \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \sum \dot{m}_e h_e &= \sum \dot{m}_i h_i \longrightarrow \dot{m}(h_3 - h_4) = \dot{m}(h_1 - h_6)\end{aligned}$$

or,

$$\dot{m}c_p(T_3 - T_4) = \dot{m}c_p(T_1 - T_6) \longrightarrow T_3 - T_4 = T_1 - T_6$$

Thus,

$$T_4 = T_3 - T_1 + T_6 = 20^\circ\text{C} - (-10^\circ\text{C}) + (-25^\circ\text{C}) = 5^\circ\text{C} = 278 \text{ K}$$

(b) From the isentropic relations,

$$\begin{aligned}T_2 &= T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (263 \text{ K})(3)^{0.667/1.667} = 408.2 \text{ K} = 135.2^\circ\text{C} \\ T_5 &= T_4 \left(\frac{P_5}{P_4} \right)^{(k-1)/k} = (278 \text{ K}) \left(\frac{1}{3} \right)^{0.667/1.667} = 179.1 \text{ K} = -93.9^\circ\text{C}\end{aligned}$$

Then the COP of this ideal gas refrigeration cycle is determined from

$$\begin{aligned}\text{COP}_R &= \frac{q_L}{w_{\text{net,in}}} = \frac{q_L}{w_{\text{comp,in}} - w_{\text{turb,out}}} = \frac{h_6 - h_5}{(h_2 - h_1) - (h_4 - h_5)} \\ &= \frac{T_6 - T_5}{(T_2 - T_1) - (T_4 - T_5)} = \frac{-25^\circ\text{C} - (-93.9^\circ\text{C})}{[135.2 - (-10)]^\circ\text{C} - [5 - (-93.9)]^\circ\text{C}} = \mathbf{1.49}\end{aligned}$$

(c) The net power input is determined from

$$\begin{aligned}\dot{W}_{\text{net,in}} &= \dot{W}_{\text{comp,in}} - \dot{W}_{\text{turb,out}} = \dot{m}[(h_2 - h_1) - (h_4 - h_5)] \\ &= \dot{m}c_p[(T_2 - T_1) - (T_4 - T_5)] \\ &= (0.45 \text{ kg/s})(5.1926 \text{ kJ/kg}\cdot^\circ\text{C})[(135.2 - (-10)) - [5 - (-93.9)]] \\ &= \mathbf{108.2 \text{ kW}}\end{aligned}$$

11-120 An absorption refrigeration system operating at specified conditions is considered. The minimum rate of heat supply required is to be determined.

Analysis The maximum COP that this refrigeration system can have is

$$\text{COP}_{R,\max} = \left(1 - \frac{T_0}{T_s}\right) \left(\frac{T_L}{T_0 - T_L}\right) = \left(1 - \frac{298 \text{ K}}{368 \text{ K}}\right) \left(\frac{275}{298 - 275}\right) = 2.274$$

Thus,

$$\dot{Q}_{\text{gen,min}} = \frac{\dot{Q}_L}{\text{COP}_{R,\max}} = \frac{28 \text{ kW}}{2.274} = \mathbf{12.3 \text{ kW}}$$

11-121 Problem 11-120 is reconsidered. The effect of the source temperature on the minimum rate of heat supply is to be investigated.

Analysis The problem is solved using EES, and the solution is given below.

"Input Data:"

T_L = 2 [C]

T_0 = 25 [C]

T_s = 95 [C]

Q_dot_L = 28 [kW]

"The maximum COP that this refrigeration system can have is:"

$\text{COP}_{R,\max} = (1 - (T_0 + 273)/(T_s + 273)) * ((T_L + 273)/(T_0 - T_L))$

"The minimum rate of heat supply is:"

$Q_{\text{dot_gen_min}} = Q_{\text{dot_L}} / \text{COP}_{R,\max}$

T _s [C]	Q _{gen,min} [kW]
50	30.26
75	16.3
100	11.65
125	9.32
150	7.925
175	6.994
200	6.33
225	5.831
250	5.443

11-122 A regenerative gas refrigeration cycle using air as the working fluid is considered. The effectiveness of the regenerator, the rate of heat removal from the refrigerated space, the COP of the cycle, and the refrigeration load and the COP if this system operated on the simple gas refrigeration cycle are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible. 3 Air is an ideal gas with variable specific heats.

Analysis (a) For this problem, we use the properties of air from EES. Note that for an ideal gas enthalpy is a function of temperature only while entropy is functions of both temperature and pressure.

$$\begin{aligned}
 T_1 &= 0^\circ\text{C} \longrightarrow h_1 = 273.40 \text{ kJ/kg} \\
 P_1 &= 100 \text{ kPa} \\
 T_1 &= 0^\circ\text{C} \quad \left. \vphantom{\begin{array}{l} T_1 \\ P_1 \end{array}} \right\} s_1 = 5.6110 \text{ kJ/kg}\cdot\text{K} \\
 P_2 &= 500 \text{ kPa} \\
 s_2 &= s_1 \quad \left. \vphantom{\begin{array}{l} P_2 \\ s_2 \end{array}} \right\} h_{2s} = 433.50 \text{ kJ/kg} \\
 \eta_C &= \frac{h_{2s} - h_1}{h_2 - h_1} \\
 0.80 &= \frac{433.50 - 273.40}{h_2 - 273.40} \\
 h_2 &= 473.52 \text{ kJ/kg} \\
 T_3 &= 35^\circ\text{C} \longrightarrow h_3 = 308.63 \text{ kJ/kg}
 \end{aligned}$$

For the turbine inlet and exit we have

$$\begin{aligned}
 T_5 &= -80^\circ\text{C} \longrightarrow h_5 = 193.45 \text{ kJ/kg} \\
 T_4 &= ? \longrightarrow h_4 = \\
 \eta_T &= \frac{h_4 - h_5}{h_4 - h_{5s}} \\
 P_1 &= 100 \text{ kPa} \\
 T_1 &= 0^\circ\text{C} \quad \left. \vphantom{\begin{array}{l} P_1 \\ T_1 \end{array}} \right\} s_1 = 5.6110 \text{ kJ/kg}\cdot\text{K} \\
 P_4 &= 500 \text{ kPa} \\
 T_4 &= ? \quad \left. \vphantom{\begin{array}{l} P_4 \\ T_4 \end{array}} \right\} s_4 = \\
 P_5 &= 500 \text{ kPa} \\
 s_5 &= s_4 \quad \left. \vphantom{\begin{array}{l} P_5 \\ s_5 \end{array}} \right\} h_{5s} =
 \end{aligned}$$

We can determine the temperature at the turbine inlet from EES using the above relations. A hand solution would require a trial-error approach.

$$T_4 = 281.8 \text{ K}, \quad h_4 = 282.08 \text{ kJ/kg}$$

An energy balance on the regenerator gives

$$h_6 = h_1 - h_3 + h_4 = 273.40 - 308.63 + 282.08 = 246.85 \text{ kJ/kg}$$

The effectiveness of the regenerator is determined from

$$\varepsilon_{\text{regen}} = \frac{h_3 - h_4}{h_3 - h_6} = \frac{308.63 - 282.08}{308.63 - 246.85} = \mathbf{0.430}$$

(b) The refrigeration load is

$$\dot{Q}_L = \dot{m}(h_6 - h_5) = (0.4 \text{ kg/s})(246.85 - 193.45) \text{ kJ/kg} = \mathbf{21.36 \text{ kW}}$$

(c) The turbine and compressor powers and the COP of the cycle are

$$\dot{W}_{C,in} = \dot{m}(h_2 - h_1) = (0.4 \text{ kg/s})(473.52 - 273.40) \text{ kJ/kg} = 80.05 \text{ kW}$$

$$\dot{W}_{T,out} = \dot{m}(h_4 - h_5) = (0.4 \text{ kg/s})(282.08 - 193.45) \text{ kJ/kg} = 35.45 \text{ kW}$$

$$\text{COP} = \frac{\dot{Q}_L}{\dot{W}_{\text{net,in}}} = \frac{\dot{Q}_L}{\dot{W}_{C,in} - \dot{W}_{T,out}} = \frac{21.36}{80.05 - 35.45} = \mathbf{0.479}$$

(d) The simple gas refrigeration cycle analysis is as follows:

$$h_1 = 273.40 \text{ kJ/kg}$$

$$h_2 = 473.52 \text{ kJ/kg}$$

$$h_3 = 308.63 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_3 = 500 \text{ kPa} \\ T_3 = 35^\circ\text{C} \end{array} \right\} s_3 = 5.2704 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_1 = 100 \text{ kPa} \\ s_4 = s_3 \end{array} \right\} h_{4s} = 194.52 \text{ kJ/kg.K}$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} \rightarrow 0.85 = \frac{308.63 - h_4}{308.63 - 194.52} \rightarrow h_4 = 211.64 \text{ kJ/kg}$$

$$\dot{Q}_L = \dot{m}(h_1 - h_4) = (0.4 \text{ kg/s})(273.40 - 211.64) \text{ kJ/kg} = \mathbf{24.70 \text{ kW}}$$

$$\dot{W}_{\text{net,in}} = \dot{m}(h_2 - h_1) - \dot{m}(h_3 - h_4) = (0.4 \text{ kg/s})[(473.52 - 273.40) - (308.63 - 211.64) \text{ kJ/kg}] = 41.25 \text{ kW}$$

$$\text{COP} = \frac{\dot{Q}_L}{\dot{W}_{\text{net,in}}} = \frac{24.70}{41.25} = \mathbf{0.599}$$

The complete EES code for the solution of this problem is given next:

11-123 An innovative vapor-compression refrigeration system with a heat exchanger is considered. The system's COP is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the refrigerant tables (Tables A-11, A-12, and A-13),

$$\left. \begin{array}{l} P_3 = 900 \text{ kPa} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 900 \text{ kPa} = 101.62 \text{ kJ/kg}$$

$$\left. \begin{array}{l} T_4 = T_{\text{sat} @ 900 \text{ kPa}} - 11.3 \\ = 35.51 - 5.51 = 30^\circ \text{C} \\ P_4 = 900 \text{ kPa} \end{array} \right\} h_4 \cong h_f @ 30^\circ \text{C} = 93.58 \text{ kJ/kg}$$

$$h_5 \cong h_4 = 93.58 \text{ kJ/kg} \quad (\text{throttling})$$

$$\left. \begin{array}{l} T_6 = -10.09^\circ \text{C} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} h_6 = h_g @ -10.09^\circ \text{C} = 244.50 \text{ kJ/kg} \\ P_6 = P_{\text{sat} @ -10.09^\circ \text{C}} = 200 \text{ kPa} \end{array}$$

An energy balance on the heat exchanger gives

$$\dot{m}(h_1 - h_6) = \dot{m}(h_3 - h_4) \longrightarrow h_1 = h_3 - h_4 + h_6 = 101.62 - 93.58 + 244.50 = 252.54 \text{ kJ/kg}$$

Then,

$$\left. \begin{array}{l} P_1 = 200 \text{ kPa} \\ h_1 = 252.54 \text{ kJ/kg} \end{array} \right\} s_1 = 0.9679 \text{ kJ/kg} \cdot \text{K}$$

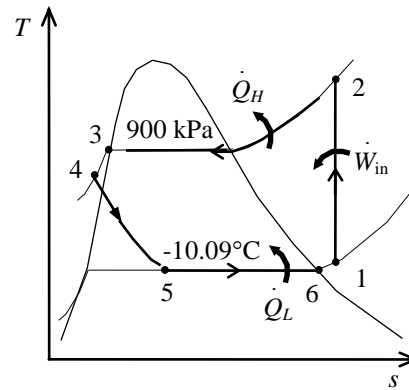

$$\left. \begin{array}{l} P_2 = 900 \text{ kPa} \\ s_2 = s_1 \end{array} \right\} h_2 = 285.37 \text{ kJ/kg}$$

The COP of this refrigeration system is determined from its definition,

$$\text{COP}_R = \frac{q_L}{w_{\text{in}}} = \frac{h_6 - h_5}{h_2 - h_1} = \frac{244.50 - 93.58}{285.37 - 252.54} = \mathbf{4.60}$$

11-124 An innovative vapor-compression refrigeration system with a heat exchanger is considered. The system's COP is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis From the refrigerant tables (Tables A-11, A-12, and A-13),

$$\left. \begin{array}{l} P_3 = 900 \text{ kPa} \\ \text{sat. liquid} \end{array} \right\} h_3 = h_f @ 900 \text{ kPa} = 101.62 \text{ kJ/kg}$$

$$\left. \begin{array}{l} T_4 = T_{\text{sat} @ 900 \text{ kPa}} - 9.51 \\ = 35.51 - 9.51 = 26^\circ\text{C} \\ P_4 = 900 \text{ kPa} \end{array} \right\} h_4 \cong h_f @ 26^\circ\text{C} = 87.82 \text{ kJ/kg}$$

$$h_5 \cong h_4 = 87.82 \text{ kJ/kg} \quad (\text{throttling})$$

$$\left. \begin{array}{l} T_6 = -10.09^\circ\text{C} \\ \text{sat. vapor} \end{array} \right\} \begin{array}{l} h_6 = h_g @ -10.09^\circ\text{C} = 244.50 \text{ kJ/kg} \\ P_6 = P_{\text{sat} @ -10.09^\circ\text{C}} = 200 \text{ kPa} \end{array}$$

An energy balance on the heat exchanger gives

$$\dot{m}(h_1 - h_6) = \dot{m}(h_3 - h_4) \longrightarrow h_1 = h_3 - h_4 + h_6 = 101.62 - 87.82 + 244.50 = 258.29 \text{ kJ/kg}$$

Then,

$$\left. \begin{array}{l} P_1 = 200 \text{ kPa} \\ h_1 = 258.29 \text{ kJ/kg} \end{array} \right\} s_1 = 0.9888 \text{ kJ/kg} \cdot \text{K}$$

$$\left. \begin{array}{l} P_2 = 900 \text{ kPa} \\ s_2 = s_1 \end{array} \right\} h_2 = 292.19 \text{ kJ/kg}$$

The COP of this refrigeration system is determined from its definition,

$$\text{COP}_R = \frac{q_L}{w_{\text{in}}} = \frac{h_6 - h_5}{h_2 - h_1} = \frac{244.50 - 87.82}{292.19 - 258.29} = \mathbf{4.62}$$

11-125 An ideal gas refrigeration cycle with with three stages of compression with intercooling using air as the working fluid is considered. The COP of this system is to be determined.

Assumptions 1 Steady operating conditions exist. **2** Air is an ideal gas with constant specific heats. **3** Kinetic and potential energy changes are negligible.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$ (Table A-2a).

Analysis From the isentropic relations,

$$T_2 = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (243 \text{ K})(7)^{0.4/1.4} = 423.7 \text{ K}$$

$$T_4 = T_6 = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = (288 \text{ K})(7)^{0.4/1.4} = 502.2 \text{ K}$$

$$T_8 = T_7 \left(\frac{P_8}{P_7} \right)^{(k-1)/k} = (288 \text{ K}) \left(\frac{1}{7 \times 7 \times 7} \right)^{0.4/1.4} = 54.3 \text{ K}$$

The COP of this ideal gas refrigeration cycle is determined from

$$\begin{aligned} \text{COP}_R &= \frac{q_L}{w_{\text{net,in}}} = \frac{q_L}{w_{\text{comp,in}} - w_{\text{turb,out}}} \\ &= \frac{h_1 - h_8}{(h_2 - h_1) + (h_4 - h_3) + (h_6 - h_5) - (h_7 - h_8)} \\ &= \frac{T_1 - T_8}{(T_2 - T_1) + 2(T_4 - T_3) - (T_7 - T_8)} \\ &= \frac{243 - 54.3}{(423.7 - 243) + 2(502.2 - 288) - (288 - 54.3)} \\ &= \mathbf{0.503} \end{aligned}$$

11-126 The effect of the evaporator pressure on the COP of an ideal vapor-compression refrigeration cycle with R-134a as the working fluid is to be investigated.

Analysis The problem is solved using EES, and the solution is given below.

11-128 A relation for the COP of the two-stage refrigeration system with a flash chamber shown in Fig. 11-14 is to be derived.

Analysis The coefficient of performance is determined from

$$\text{COP}_R = \frac{q_L}{w_{\text{in}}}$$

where

$$q_L = (1 - x_6)(h_1 - h_8) \quad \text{with} \quad x_6 = \frac{h_6 - h_f}{h_{fg}}$$

$$w_{\text{in}} = w_{\text{compI, in}} + w_{\text{compII, in}} = (1 - x_6)(h_2 - h_1) + (1)(h_4 - h_3)$$

Fundamentals of Engineering (FE) Exam Problems

11-129 Consider a heat pump that operates on the reversed Carnot cycle with R-134a as the working fluid executed under the saturation dome between the pressure limits of 140 kPa and 800 kPa. R-134a changes from saturated vapor to saturated liquid during the heat rejection process. The net work input for this cycle is

- (a) 28 kJ/kg (b) 34 kJ/kg (c) 49 kJ/kg (d) 144 kJ/kg (e) 275 kJ/kg

Answer (a) 28 kJ/kg

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
P1=800 "kPa"
P2=140 "kPa"

Partial Derivatives and Associated Relations

12-1C For functions that depend on one variable, they are identical. For functions that depend on two or more variable, the partial differential represents the change in the function with one of the variables as the other variables are held constant. The ordinary differential for such functions represents the total change as a result of differential changes in all variables.

12-2C Only when $(\partial z/\partial x)_y = 0$. That is, when z does not depend on y and thus $z = z(x)$.

12-3C It indicates that z does not depend on y . That is, $z = z(x)$.

12-4C (a) $(\partial x)_y = dx$; (b) $(\partial z)_y \leq dz$; and (c) $dz = (\partial z)_x + (\partial z)_y$

12-5 Air at a specified temperature and specific volume is considered. The changes in pressure corresponding to a certain increase of different properties are to be determined.

Assumptions Air is an ideal gas.

Properties The gas constant of air is $R = 0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K}$ (Table A-1).

Analysis An ideal gas equation can be expressed as $P = RT/\nu$. Noting that R is a constant and $P = P(T, \nu)$,

$$dP = \left(\frac{\partial P}{\partial T} \right)_{\nu} dT + \left(\frac{\partial P}{\partial \nu} \right)_{T} d\nu = \frac{RdT}{\nu} - \frac{RTd\nu}{\nu^2}$$

(a) The change in T can be expressed as $dT \cong \Delta T = 350 \times 0.01 = 3.5 \text{ K}$. At $\nu = \text{constant}$,

$$(dP)_{\nu} = \frac{RdT}{\nu} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(3.5 \text{ K})}{0.75 \text{ m}^3/\text{kg}} = \mathbf{1.339 \text{ kPa}}$$

(b) The change in ν can be expressed as $d\nu \cong \Delta \nu = 0.75 \times 0.01 = 0.0075 \text{ m}^3/\text{kg}$. At $T = \text{constant}$,

$$(dP)_T = -\frac{RTd\nu}{\nu^2} = -\frac{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(300 \text{ K})(0.0075 \text{ m}^3/\text{kg})}{(0.75 \text{ m}^3/\text{kg})^2} = \mathbf{-1.339 \text{ kPa}}$$

(c) When both ν and T increases by 1%, the change in P becomes

$$dP = (dP)_{\nu} + (dP)_T = 1.339 + (-1.339) = \mathbf{0}$$

Thus the changes in T and ν balance each other.

12-6 Helium at a specified temperature and specific volume is considered. The changes in pressure corresponding to a certain increase of different properties are to be determined.

Assumptions Helium is an ideal gas

Properties The gas constant of helium is $R = 2.0769 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K}$ (Table A-1).

Analysis An ideal gas equation can be expressed as $P = RT/\nu$. Noting that R is a constant and $P = P(T, \nu)$,

$$dP = \left(\frac{\partial P}{\partial T} \right)_{\nu} dT + \left(\frac{\partial P}{\partial \nu} \right)_{T} d\nu = \frac{RdT}{\nu} - \frac{RTd\nu}{\nu^2}$$

(a) The change in T can be expressed as $dT \cong \Delta T = 350 \times 0.01 = 3.5 \text{ K}$. At $\nu = \text{constant}$,

$$(dP)_{\nu} = \frac{RdT}{\nu} = \frac{(2.0769 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(3.5 \text{ K})}{0.75 \text{ m}^3/\text{kg}} = \mathbf{9.692 \text{ kPa}}$$

(b) The change in ν can be expressed as $d\nu \cong \Delta \nu = 0.75 \times 0.01 = 0.0075 \text{ m}^3/\text{kg}$. At $T = \text{constant}$,

$$(dP)_{T} = -\frac{RTd\nu}{\nu^2} = \frac{(2.0769 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(300 \text{ K})(0.0075 \text{ m}^3)}{(0.75 \text{ m}^3/\text{kg})^2} = \mathbf{-9.692 \text{ kPa}}$$

(c) When both ν and T increases by 1%, the change in P becomes

$$dP = (dP)_{\nu} + (dP)_{T} = 9.692 + (-9.692) = \mathbf{0}$$

Thus the changes in T and ν balance each other.

12-7 Nitrogen gas at a specified state is considered. The c_p and c_v of the nitrogen are to be determined using Table A-18, and to be compared to the values listed in Table A-2b.

Analysis The c_p and c_v of ideal gases depends on temperature only, and are expressed as $c_p(T) = dh(T)/dT$ and $c_v(T) = du(T)/dT$. Approximating the differentials as differences about 400 K, the c_p and c_v values are determined to be

$$\begin{aligned} c_p(400 \text{ K}) &= \left(\frac{dh(T)}{dT} \right)_{T=400 \text{ K}} \cong \left(\frac{\Delta h(T)}{\Delta T} \right)_{T \cong 400 \text{ K}} \\ &= \frac{h(410 \text{ K}) - h(390 \text{ K})}{(410 - 390) \text{ K}} \\ &= \frac{(11,932 - 11,347) \text{ kJ/kg}}{(410 - 390) \text{ K}} \\ &= \mathbf{1.045 \text{ kJ/kg} \cdot \text{K}} \end{aligned}$$

(Compare: Table A-2b at 400 K $\rightarrow c_p = 1.044 \text{ kJ/kg} \cdot \text{K}$)

$$\begin{aligned} c_v(400 \text{ K}) &= \left(\frac{du(T)}{dT} \right)_{T=400 \text{ K}} \cong \left(\frac{\Delta u(T)}{\Delta T} \right)_{T \cong 400 \text{ K}} \\ &= \frac{u(410 \text{ K}) - u(390 \text{ K})}{(410 - 390) \text{ K}} \\ &= \frac{(8,523 - 8,104) \text{ kJ/kg}}{(410 - 390) \text{ K}} = \mathbf{0.748 \text{ kJ/kg} \cdot \text{K}} \end{aligned}$$

(Compare: Table A-2b at 400 K $\rightarrow c_v = 0.747 \text{ kJ/kg} \cdot \text{K}$)

12-8E Nitrogen gas at a specified state is considered. The c_p and c_v of the nitrogen are to be determined using Table A-18E, and to be compared to the values listed in Table A-2Eb.

Analysis The c_p and c_v of ideal gases depends on temperature only, and are expressed as $c_p(T) = dh(T)/dT$ and $c_v(T) = du(T)/dT$. Approximating the differentials as differences about 600 R, the c_p and c_v values are determined to be

$$\begin{aligned} c_p(800 \text{ R}) &= \left(\frac{dh(T)}{dT} \right)_{T=800 \text{ R}} \cong \left(\frac{\Delta h(T)}{\Delta T} \right)_{T \cong 800 \text{ R}} \\ &= \frac{h(820 \text{ R}) - h(780 \text{ R})}{(820 - 780) \text{ R}} \\ &= \frac{(5704.7 - 5424.2)/28.013 \text{ Btu/lbm}}{(820 - 780) \text{ R}} = \mathbf{0.250 \text{ Btu/lbm} \cdot \text{R}} \end{aligned}$$

(Compare: Table A-2Eb at 800 R = 340°F → $c_p = 0.250 \text{ Btu/lbm} \cdot \text{R}$)

$$\begin{aligned} c_v(800 \text{ R}) &= \left(\frac{du(T)}{dT} \right)_{T=800 \text{ R}} \cong \left(\frac{\Delta u(T)}{\Delta T} \right)_{T \cong 800 \text{ R}} \\ &= \frac{u(820 \text{ R}) - u(780 \text{ R})}{(820 - 780) \text{ R}} \\ &= \frac{(4076.3 - 3875.2)/28.013 \text{ Btu/lbm}}{(820 - 780) \text{ R}} = \mathbf{0.179 \text{ Btu/lbm} \cdot \text{R}} \end{aligned}$$

(Compare: Table A-2Eb at 800 R = 340°F → $c_v = 0.179 \text{ Btu/lbm} \cdot \text{R}$)

12-9 The state of an ideal gas is altered slightly. The change in the specific volume of the gas is to be determined using differential relations and the ideal-gas relation at each state.

Assumptions The gas is air and air is an ideal gas.

Properties The gas constant of air is $R = 0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K}$ (Table A-1).

Analysis (a) The changes in T and P can be expressed as

$$dT \cong \Delta T = (305 - 300)\text{K} = 5 \text{ K}$$

$$dP \cong \Delta P = (96 - 100)\text{kPa} = -4 \text{ kPa}$$

The ideal gas relation $P\nu = RT$ can be expressed as $\nu = RT/P$. Note that R is a constant and $\nu = \nu(T, P)$. Applying the total differential relation and using average values for T and P ,

$$\begin{aligned} d\nu &= \left(\frac{\partial \nu}{\partial T} \right)_P dT + \left(\frac{\partial \nu}{\partial P} \right)_T dP = \frac{RdT}{P} - \frac{RTdP}{P^2} \\ &= (0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K}) \left(\frac{5 \text{ K}}{98 \text{ kPa}} - \frac{(302.5 \text{ K})(-4 \text{ kPa})}{(98 \text{ kPa})^2} \right) \\ &= (0.01464 \text{ m}^3/\text{kg}) + (0.03616 \text{ m}^3/\text{kg}) \\ &= \mathbf{0.0508 \text{ m}^3/\text{kg}} \end{aligned}$$

(b) Using the ideal gas relation at each state,

$$\begin{aligned} \nu_1 &= \frac{RT_1}{P_1} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(300 \text{ K})}{100 \text{ kPa}} = 0.8610 \text{ m}^3/\text{kg} \\ \nu_2 &= \frac{RT_2}{P_2} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(305 \text{ K})}{96 \text{ kPa}} = 0.9118 \text{ m}^3/\text{kg} \end{aligned}$$

Thus,

$$\Delta \nu = \nu_2 - \nu_1 = 0.9118 - 0.8610 = \mathbf{0.0508 \text{ m}^3/\text{kg}}$$

The two results are identical.

12-10 Using the equation of state $P(\nu - a) = RT$, the cyclic relation, and the reciprocity relation at constant ν are to be verified.

Analysis (a) This equation of state involves three variables P , ν , and T . Any two of these can be taken as the independent variables, with the remaining one being the dependent variable. Replacing x , y , and z by P , ν , and T , the cyclic relation can be expressed as

$$\left(\frac{\partial P}{\partial \nu}\right)_T \left(\frac{\partial \nu}{\partial T}\right)_P \left(\frac{\partial T}{\partial P}\right)_\nu = -1$$

where

$$\begin{aligned} P = \frac{RT}{\nu - a} &\longrightarrow \left(\frac{\partial P}{\partial \nu}\right)_T = \frac{-RT}{(\nu - a)^2} = -\frac{P}{\nu - a} \\ \nu = \frac{RT}{P} + a &\longrightarrow \left(\frac{\partial \nu}{\partial T}\right)_P = \frac{R}{P} \\ T = \frac{P(\nu - a)}{R} &\longrightarrow \left(\frac{\partial T}{\partial P}\right)_\nu = \frac{\nu - a}{R} \end{aligned}$$

Substituting,

$$\left(\frac{\partial P}{\partial \nu}\right)_T \left(\frac{\partial \nu}{\partial T}\right)_P \left(\frac{\partial T}{\partial P}\right)_\nu = \left(-\frac{P}{\nu - a}\right) \left(\frac{R}{P}\right) \left(\frac{\nu - a}{R}\right) = -1$$

which is the desired result.

(b) The reciprocity rule for this gas at $\nu = \text{constant}$ can be expressed as

$$\begin{aligned} \left(\frac{\partial P}{\partial T}\right)_\nu &= \frac{1}{(\partial T / \partial P)_\nu} \\ T = \frac{P(\nu - a)}{R} &\longrightarrow \left(\frac{\partial T}{\partial P}\right)_\nu = \frac{\nu - a}{R} \\ P = \frac{RT}{\nu - a} &\longrightarrow \left(\frac{\partial P}{\partial T}\right)_\nu = \frac{R}{\nu - a} \end{aligned}$$

We observe that the first differential is the inverse of the second one. Thus the proof is complete.

12-11 A relation is to be derived for the slope of the $\nu = \text{constant}$ lines on a T - P diagram for a gas that obeys the van der Waals equation of state.

Analysis The van der Waals equation of state can be expressed as

$$T = \frac{1}{R} \left(P + \frac{a}{\nu^2} \right) (\nu - b)$$

Taking the derivative of T with respect to P holding ν constant,

$$\left(\frac{\partial T}{\partial P}\right)_\nu = \frac{1}{R} (1+0)(\nu - b) = \frac{\nu - b}{R}$$

which is the slope of the $\nu = \text{constant}$ lines on a T - P diagram.

The Maxwell Relations

12-12 The validity of the last Maxwell relation for refrigerant-134a at a specified state is to be verified.

Analysis We do not have exact analytical property relations for refrigerant-134a, and thus we need to replace the differential quantities in the last Maxwell relation with the corresponding finite quantities. Using property values from the tables about the specified state,

$$\begin{aligned} \left(\frac{\partial s}{\partial p}\right)_T &\stackrel{?}{=} -\left(\frac{\partial v}{\partial T}\right)_p \\ \left(\frac{\Delta s}{\Delta p}\right)_{T=50^\circ\text{C}} &\stackrel{?}{\cong} -\left(\frac{\Delta v}{\Delta T}\right)_{p=700\text{kPa}} \\ \left(\frac{s_{900\text{kPa}} - s_{500\text{kPa}}}{(900 - 500)\text{kPa}}\right)_{T=50^\circ\text{C}} &\stackrel{?}{\cong} -\left(\frac{v_{70^\circ\text{C}} - v_{30^\circ\text{C}}}{(70 - 30)^\circ\text{C}}\right)_{p=700\text{kPa}} \\ \frac{(0.9661 - 1.0309)\text{kJ/kg} \cdot \text{K}}{(900 - 500)\text{kPa}} &\stackrel{?}{\cong} -\frac{(0.036373 - 0.029966)\text{m}^3/\text{kg}}{(70 - 30)^\circ\text{C}} \\ &= -1.621 \times 10^{-4} \text{ m}^3/\text{kg} \cdot \text{K} \cong -1.602 \times 10^{-4} \text{ m}^3/\text{kg} \cdot \text{K} \end{aligned}$$

since $\text{kJ} \equiv \text{kPa} \cdot \text{m}^3$, and $\text{K} \equiv ^\circ\text{C}$ for temperature differences. Thus the last Maxwell relation is satisfied.

12-13 Problem 12-12 is reconsidered. The validity of the last Maxwell relation for refrigerant 134a at the specified state is to be verified.

Analysis The problem is solved using EES, and the solution is given below.

"Input Data:"

12-14E The validity of the last Maxwell relation for steam at a specified state is to be verified.

Analysis We do not have exact analytical property relations for steam, and thus we need to replace the differential quantities in the last Maxwell relation with the corresponding finite quantities. Using property values from the tables about the specified state,

$$\begin{aligned} \left(\frac{\partial s}{\partial P}\right)_T &\stackrel{?}{=} -\left(\frac{\partial v}{\partial T}\right)_P \\ \left(\frac{\Delta s}{\Delta P}\right)_{T=60^\circ\text{F}} &\stackrel{?}{\cong} -\left(\frac{\Delta v}{\Delta T}\right)_{P=275\text{psia}} \\ \left(\frac{s_{300\text{psia}} - s_{250\text{psia}}}{(300 - 250)\text{psia}}\right)_{T=60^\circ\text{F}} &\stackrel{?}{\cong} -\left(\frac{v_{650^\circ\text{F}} - v_{550^\circ\text{F}}}{(650 - 550)^\circ\text{F}}\right)_{P=275\text{psia}} \\ \frac{(1.6270 - 1.6499)\text{Btu/lbm}\cdot\text{R}}{(300 - 250)\text{psia}} &\stackrel{?}{\cong} -\frac{(2.3179 - 2.0715)\text{ft}^3/\text{lbm}}{(650 - 550)^\circ\text{F}} \\ &\cong -2.466 \times 10^{-3} \text{ft}^3/\text{lbm}\cdot\text{R} \cong -2.464 \times 10^{-3} \text{ft}^3/\text{lbm}\cdot\text{R} \end{aligned}$$

since $1 \text{ Btu} = 5.4039 \text{ psia}\cdot\text{ft}^3$, and $\text{R} \equiv ^\circ\text{F}$ for temperature differences. Thus the fourth Maxwell relation is satisfied.

12-15 Using the Maxwell relations, a relation for $(\partial s/\partial P)_T$ for a gas whose equation of state is $P(v-b) = RT$ is to be obtained.

Analysis This equation of state can be expressed as $v = \frac{RT}{P} + b$. Then,

$$\left(\frac{\partial v}{\partial T}\right)_P = \frac{R}{P}$$

From the fourth Maxwell relation,

$$\left(\frac{\partial s}{\partial P}\right)_T = -\left(\frac{\partial v}{\partial T}\right)_P = -\frac{R}{P}$$

12-16 Using the Maxwell relations, a relation for $(\partial s/\partial v)_T$ for a gas whose equation of state is $(P-a/v^2)(v-b) = RT$ is to be obtained.

Analysis This equation of state can be expressed as $P = \frac{RT}{v-b} + \frac{a}{v^2}$. Then,

$$\left(\frac{\partial P}{\partial T}\right)_v = \frac{R}{v-b}$$

From the third Maxwell relation,

$$\left(\frac{\partial s}{\partial v}\right)_T = \left(\frac{\partial P}{\partial T}\right)_v = \frac{R}{v-b}$$

12-17 Using the Maxwell relations and the ideal-gas equation of state, a relation for $(\partial s/\partial v)_T$ for an ideal gas is to be obtained.

Analysis The ideal gas equation of state can be expressed as $P = \frac{RT}{v}$. Then,

$$\left(\frac{\partial P}{\partial T}\right)_v = \frac{R}{v}$$

From the third Maxwell relation,

$$\left(\frac{\partial s}{\partial v}\right)_T = \left(\frac{\partial P}{\partial T}\right)_v = \frac{R}{v}$$

12-18 It is to be proven that $\left(\frac{\partial P}{\partial T}\right)_s = \frac{k}{k-1} \left(\frac{\partial P}{\partial T}\right)_v$

Analysis Using the definition of c_v ,

$$c_v = T \left(\frac{\partial s}{\partial T}\right)_v = T \left(\frac{\partial s}{\partial P}\right)_v \left(\frac{\partial P}{\partial T}\right)_v$$

Substituting the first Maxwell relation $\left(\frac{\partial s}{\partial P}\right)_v = -\left(\frac{\partial v}{\partial T}\right)_s$,

$$c_v = -T \left(\frac{\partial v}{\partial T}\right)_s \left(\frac{\partial P}{\partial T}\right)_v$$

Using the definition of c_p ,

$$c_p = T \left(\frac{\partial s}{\partial T}\right)_p = T \left(\frac{\partial s}{\partial v}\right)_p \left(\frac{\partial v}{\partial T}\right)_p$$

Substituting the second Maxwell relation $\left(\frac{\partial s}{\partial v}\right)_p = \left(\frac{\partial P}{\partial T}\right)_s$,

$$c_p = T \left(\frac{\partial P}{\partial T}\right)_s \left(\frac{\partial v}{\partial T}\right)_p$$

From Eq. 12-46,

$$c_p - c_v = -T \left(\frac{\partial v}{\partial T}\right)_p^2 \left(\frac{\partial P}{\partial v}\right)_T$$

Also,

$$\frac{k}{k-1} = \frac{c_p}{c_p - c_v}$$

Then,

$$\frac{k}{k-1} = -\frac{\left(\frac{\partial P}{\partial T}\right)_s \left(\frac{\partial v}{\partial T}\right)_p}{\left(\frac{\partial v}{\partial T}\right)_p^2 \left(\frac{\partial P}{\partial v}\right)_T} = -\left(\frac{\partial P}{\partial T}\right)_s \left(\frac{\partial T}{\partial v}\right)_p \left(\frac{\partial v}{\partial P}\right)_T$$

Substituting this into the original equation in the problem statement produces

$$\left(\frac{\partial P}{\partial T}\right)_s = -\left(\frac{\partial P}{\partial T}\right)_s \left(\frac{\partial T}{\partial v}\right)_p \left(\frac{\partial v}{\partial P}\right)_T \left(\frac{\partial P}{\partial T}\right)_v$$

But, according to the cyclic relation, the last three terms are equal to -1 . Then,

$$\left(\frac{\partial P}{\partial T}\right)_s = \left(\frac{\partial P}{\partial T}\right)_s$$

The Clapeyron Equation

12-19C It enables us to determine the enthalpy of vaporization from h_{fg} at a given temperature from the P, v, T data alone.

12-20C It is exact.

12-21 Using the Clapeyron equation, the enthalpy of vaporization of refrigerant-134a at a specified temperature is to be estimated and to be compared to the tabulated data.

Analysis From the Clapeyron equation,

$$\begin{aligned}
 h_{fg} &= T \nu_{fg} \left(\frac{dP}{dT} \right)_{\text{sat}} \\
 &\cong T (\nu_g - \nu_f)_{@40^\circ\text{C}} \left(\frac{\Delta P}{\Delta T} \right)_{\text{sat}, 40^\circ\text{C}} \\
 &= T (\nu_g - \nu_f)_{@40^\circ\text{C}} \left(\frac{P_{\text{sat}@42^\circ\text{C}} - P_{\text{sat}@38^\circ\text{C}}}{42^\circ\text{C} - 38^\circ\text{C}} \right) \\
 &= (40 + 273.15 \text{ K})(0.019968 - 0.0008720 \text{ m}^3/\text{kg}) \left(\frac{(1072.8 - 963.68) \text{ kPa}}{4 \text{ K}} \right) \\
 &= \mathbf{163.13 \text{ kJ/kg}}
 \end{aligned}$$

The tabulated value of h_{fg} at 40°C is **163.03 kJ/kg**.

12-22 Problem 12-21 is reconsidered. The enthalpy of vaporization of refrigerant 134-a as a function of temperature over the temperature range -20 to 80°C by using the Clapeyron equation and the refrigerant 134-a data in EES is to be plotted.

Analysis The problem is solved using EES, and the results are tabulated and plotted below.

"Input Data:"

```
T=30 [C]
T_increment = 5 [C]

T[2]=T+T_increment
T[1]=T-T_increment
P[1] = pressure(R134a,T=T[1],x=0)
P[2] = pressure(R134a,T=T[2],x=0)
DELTAP = P[2]-P[1]
DELTAT = T[2]-T[1]
```

```
v_f=volume(R134a,T=T,x=0)
v_g=volume(R134a,T=T,x=1)
h_f=enthalpy(R134a,T=T,x=0)
h_g=enthalpy(R134a,T=T,x=1)
```

```
h_fg=h_g - h_f
v_fg=v_g - v_f
```

"The Clapeyron equation (Eq. 12-22) provides a means to calculate the enthalpy of vaporization, h_{fg} at a given temperature by determining the slope of the saturation curve on a P-T diagram and the specific volume of the saturated liquid and saturated vapor at the temperature."

```
h_fg_Clapeyron=(T+273.2)*v_fg*DELTAP/DELTAT*Convert(m^3-kPa,kJ)
PercentError=ABS(h_fg_Clapeyron-h_fg)/h_fg*Convert(, %) "[%]"
```

T [C]	h_{fg} [kJ/kg]	$h_{fg,Clapeyron}$ [kJ/kg]	PercentError [%]
-20	212.96	213.76	0.3752
-10	206.02	206.73	0.3454
0	198.67	199.28	0.3118
10	190.80	191.32	0.2711
20	182.33	182.74	0.228
30	173.13	173.46	0.1917
40	163.03	163.31	0.1724
50	151.82	152.08	0.1748
60	139.09	139.26	0.1222
70	124.37	124.61	0.1931
80	106.35	106.51	0.1437

12-23 Using the Clapeyron equation, the enthalpy of vaporization of steam at a specified pressure is to be estimated and to be compared to the tabulated data.

Analysis From the Clapeyron equation,

$$\begin{aligned}
 h_{fg} &= T \nu_{fg} \left(\frac{dP}{dT} \right)_{\text{sat}} \\
 &\cong T(\nu_g - \nu_f)_{@300 \text{ kPa}} \left(\frac{\Delta P}{\Delta T} \right)_{\text{sat}, 300 \text{ kPa}} \\
 &= T_{\text{sat}@300 \text{ kPa}} (\nu_g - \nu_f)_{@300 \text{ kPa}} \left(\frac{(325 - 275) \text{ kPa}}{T_{\text{sat}@325 \text{ kPa}} - T_{\text{sat}@275 \text{ kPa}}} \right) \\
 &= (133.52 + 273.15 \text{ K})(0.60582 - 0.001073 \text{ m}^3/\text{kg}) \left(\frac{50 \text{ kPa}}{(136.27 - 130.58)^\circ\text{C}} \right) \\
 &= \mathbf{2159.9 \text{ kJ/kg}}
 \end{aligned}$$

The tabulated value of h_{fg} at 300 kPa is **2163.5 kJ/kg**.

12-24E  The h_{fg} of refrigerant-134a at a specified temperature is to be calculated using the Clapeyron equation and Clapeyron-Clausius equation and to be compared to the tabulated data.

Analysis (a) From the Clapeyron equation,

$$\begin{aligned}
 h_{fg} &= T \nu_{fg} \left(\frac{dP}{dT} \right)_{\text{sat}} \\
 &\cong T(\nu_g - \nu_f)_{@10^\circ\text{F}} \left(\frac{\Delta P}{\Delta T} \right)_{\text{sat}, 10^\circ\text{F}} \\
 &= T(\nu_g - \nu_f)_{@10^\circ\text{F}} \left(\frac{P_{\text{sat}@15^\circ\text{F}} - P_{\text{sat}@5^\circ\text{F}}}{15^\circ\text{F} - 5^\circ\text{F}} \right) \\
 &= (10 + 459.67 \text{ R})(1.7358 - 0.01200 \text{ ft}^3/\text{lbm}) \left(\frac{(29.759 - 23.793) \text{ psia}}{10 \text{ R}} \right) \\
 &= 483.0 \text{ psia} \cdot \text{ft}^3/\text{lbm} = \mathbf{89.38 \text{ Btu/lbm}} \quad (0.1\% \text{ error})
 \end{aligned}$$

since $1 \text{ Btu} = 5.4039 \text{ psia} \cdot \text{ft}^3$.

(b) From the Clapeyron-Clausius equation,

$$\begin{aligned}
 \ln \left(\frac{P_2}{P_1} \right)_{\text{sat}} &\cong \frac{h_{fg}}{R} \left(\frac{1}{T_1} - \frac{1}{T_2} \right)_{\text{sat}} \\
 \ln \left(\frac{23.793 \text{ psia}}{29.759 \text{ psia}} \right) &\cong \frac{h_{fg}}{0.01946 \text{ Btu/lbm} \cdot \text{R}} \left(\frac{1}{15 + 459.67 \text{ R}} - \frac{1}{5 + 459.67 \text{ R}} \right) \\
 h_{fg} &= \mathbf{96.04 \text{ Btu/lbm}} \quad (7.6\% \text{ error})
 \end{aligned}$$

The tabulated value of h_{fg} at 10°F is **89.25 Btu/lbm**.

12-25E A substance is cooled in a piston-cylinder device until it turns from saturated vapor to saturated liquid at a constant pressure and temperature. The boiling temperature of this substance at a different pressure is to be estimated.

Analysis From the Clapeyron equation,

$$\left(\frac{dP}{dT}\right)_{\text{sat}} = \frac{h_{fg}}{T\nu_{fg}} = \frac{(250 \text{ Btu})\left(\frac{5.404 \text{ psia} \cdot \text{ft}^3}{1 \text{ Btu}}\right)/(0.5 \text{ lbm})}{(475 \text{ R})(1.5 \text{ ft}^3)/(0.5 \text{ lbm})} = 1.896 \text{ psia/R}$$

Using the finite difference approximation,

$$\left(\frac{dP}{dT}\right)_{\text{sat}} \approx \left(\frac{P_2 - P_1}{T_2 - T_1}\right)_{\text{sat}}$$

Solving for T_2 ,

$$T_2 = T_1 + \frac{P_2 - P_1}{dP/dT} = 475 \text{ R} + \frac{(60 - 50) \text{ psia}}{1.896 \text{ psia/R}} = \mathbf{480.3 \text{ R}}$$

12-26E A substance is cooled in a piston-cylinder device until it turns from saturated vapor to saturated liquid at a constant pressure and temperature. The saturation pressure of this substance at a different temperature is to be estimated.

Analysis From the Clapeyron equation,

$$\left(\frac{dP}{dT}\right)_{\text{sat}} = \frac{h_{fg}}{T\nu_{fg}} = \frac{(250 \text{ Btu})\left(\frac{5.404 \text{ psia} \cdot \text{ft}^3}{1 \text{ Btu}}\right)/(0.5 \text{ lbm})}{(475 \text{ R})(1.5 \text{ ft}^3)/(0.5 \text{ lbm})} = 1.896 \text{ psia/R}$$

Using the finite difference approximation,

$$\left(\frac{dP}{dT}\right)_{\text{sat}} \approx \left(\frac{P_2 - P_1}{T_2 - T_1}\right)_{\text{sat}}$$

Solving for P_2 ,

$$P_2 = P_1 + \frac{dP}{dT}(T_2 - T_1) = 50 \text{ psia} + (1.896 \text{ psia/R})(480 - 475) \text{ R} = \mathbf{59.5 \text{ psia}}$$

12-27E A substance is cooled in a piston-cylinder device until it turns from saturated vapor to saturated liquid at a constant pressure and temperature. The s_{fg} of this substance at the given temperature is to be estimated.

Analysis From the Clapeyron equation,

$$\left(\frac{dP}{dT}\right)_{\text{sat}} = \frac{h_{fg}}{T\nu_{fg}} = \frac{s_{fg}}{\nu_{fg}}$$

Solving for s_{fg} ,

$$s_{fg} = \frac{h_{fg}}{T} = \frac{(250 \text{ Btu})/(0.5 \text{ lbm})}{475 \text{ R}} = \mathbf{1.053 \text{ Btu/lbm} \cdot \text{R}}$$

Alternatively,

$$s_{fg} = \left(\frac{dP}{dT}\right)_{\text{sat}} \nu_{fg} = (1.896 \text{ psia/R}) \frac{1.5 \text{ ft}^3}{0.5 \text{ lbm}} \left(\frac{1 \text{ Btu}}{5.404 \text{ psia} \cdot \text{ft}^3}\right) = 1.053 \text{ Btu/lbm} \cdot \text{R}$$

12-28E A table of properties for methyl chloride is given. The saturation pressure is to be estimated at two different temperatures.

Analysis The Clapeyron equation is

$$\left(\frac{dP}{dT}\right)_{\text{sat}} = \frac{h_{fg}}{T\nu_{fg}}$$

Using the finite difference approximation,

$$\left(\frac{dP}{dT}\right)_{\text{sat}} \approx \left(\frac{P_2 - P_1}{T_2 - T_1}\right)_{\text{sat}} = \frac{h_{fg}}{T\nu_{fg}}$$

Solving this for the second pressure gives for $T_2 = 110^\circ\text{F}$

$$\begin{aligned} P_2 &= P_1 + \frac{h_{fg}}{T\nu_{fg}}(T_2 - T_1) \\ &= 116.7 \text{ psia} + \frac{154.85 \text{ Btu/lbm}}{(560 \text{ R})(0.86332 \text{ ft}^3/\text{lbm})} \left(\frac{5.404 \text{ psia} \cdot \text{ft}^3}{1 \text{ Btu}}\right) (110 - 100)\text{R} \\ &= \mathbf{134.0 \text{ psia}} \end{aligned}$$

When $T_2 = 90^\circ\text{F}$

$$\begin{aligned} P_2 &= P_1 + \frac{h_{fg}}{T\nu_{fg}}(T_2 - T_1) \\ &= 116.7 \text{ psia} + \frac{154.85 \text{ Btu/lbm}}{(560 \text{ R})(0.86332 \text{ ft}^3/\text{lbm})} \left(\frac{5.404 \text{ psia} \cdot \text{ft}^3}{1 \text{ Btu}}\right) (90 - 100)\text{R} \\ &= \mathbf{99.4 \text{ psia}} \end{aligned}$$

12-29 The sublimation pressure of water at -30°C is to be determined using Clapeyron-Clasius equation and the triple point data of water.

Analysis The sublimation pressure may be determined using Clapeyron-Clasius equation from

$$\ln\left(\frac{P_{\text{sub,CC}}}{P_1}\right) = \frac{h_{ig}}{R} \left(\frac{1}{T_1} - \frac{1}{T_2}\right)$$

where the triple point properties of water are $P_1 = 0.6117 \text{ kPa}$ and $T_1 = 0.01^{\circ}\text{C} = 273.16 \text{ K}$ (first line in Table A-4). Also, the enthalpy of sublimation of water at -30°C is determined from Table A-8 to be 2838.4 kJ/kg . Substituting,

$$\ln\left(\frac{P_{\text{sub,CC}}}{P_1}\right) = \frac{h_{ig}}{R} \left(\frac{1}{T_1} - \frac{1}{T_2}\right)$$

$$\ln\left(\frac{P_{\text{sub,CC}}}{0.6117 \text{ kPa}}\right) = \frac{2838.4 \text{ kJ/kg}}{0.4615 \text{ kJ/kg}\cdot\text{K}} \left(\frac{1}{273.16 \text{ K}} - \frac{1}{-30 + 273.15 \text{ K}}\right)$$

$$P_{\text{sub,CC}} = \mathbf{0.03799 \text{ kPa}}$$

The sublimation pressure of water at -30°C is given in Table A-8 to be 0.03802 kPa . Then, the error involved in using Clapeyron-Clasius equation becomes

$$\text{PercentError} = \frac{0.03802 - 0.03799}{0.03802} \times 100 = \mathbf{0.08\%}$$

12-30 It is to be shown that $c_{p,g} - c_{p,f} = T \left(\frac{\partial(h_{fg}/T)}{\partial T} \right)_P + \nu_{fg} \left(\frac{\partial P}{\partial T} \right)_{\text{sat}}$.

Analysis The definition of specific heat and Clapeyron equation are

$$c_p = \left(\frac{\partial h}{\partial T} \right)_P$$

$$\left(\frac{dP}{dT} \right)_{\text{sat}} = \frac{h_{fg}}{T \nu_{fg}}$$

According to the definition of the enthalpy of vaporization,

$$\frac{h_{fg}}{T} = \frac{h_g}{T} - \frac{h_f}{T}$$

Differentiating this expression gives

$$\begin{aligned} \left(\frac{\partial h_{fg}/T}{\partial T} \right)_P &= \left(\frac{\partial h_g/T}{\partial T} \right)_P - \left(\frac{\partial h_f/T}{\partial T} \right)_P \\ &= \frac{1}{T} \left(\frac{\partial h_g}{\partial T} \right)_P - \frac{h_g}{T^2} - \frac{1}{T} \left(\frac{\partial h_f}{\partial T} \right)_P + \frac{h_f}{T^2} \\ &= \frac{c_{p,g}}{T} - \frac{c_{p,f}}{T} - \frac{h_g - h_f}{T^2} \end{aligned}$$

Using Clapeyron to replace the last term of this expression and solving for the specific heat difference gives

$$c_{p,g} - c_{p,f} = T \left(\frac{\partial(h_{fg}/T)}{\partial T} \right)_P + \nu_{fg} \left(\frac{\partial P}{\partial T} \right)_{\text{sat}}$$

General Relations for du , dh , ds , c_v , and c_p

12-31C Yes, through the relation

$$\left(\frac{\partial c_p}{\partial P}\right)_T = -T \left(\frac{\partial^2 v}{\partial T^2}\right)_P$$

12-32 The volume expansivity β and the isothermal compressibility α of refrigerant-134a at 200 kPa and 30°C are to be estimated.

Analysis The volume expansivity and isothermal compressibility are expressed as

$$\beta = \frac{1}{v} \left(\frac{\partial v}{\partial T}\right)_P \quad \text{and} \quad \alpha = -\frac{1}{v} \left(\frac{\partial v}{\partial P}\right)_T$$

Approximating differentials by differences about the specified state,

$$\begin{aligned} \beta &\cong \frac{1}{v} \left(\frac{\Delta v}{\Delta T}\right)_{P=200\text{kPa}} = \frac{1}{v} \left(\frac{v_{40^\circ\text{C}} - v_{20^\circ\text{C}}}{(40 - 20)^\circ\text{C}}\right)_{P=200\text{kPa}} \\ &= \frac{1}{0.11874 \text{ m}^3/\text{kg}} \left(\frac{(0.12322 - 0.11418)\text{m}^3/\text{kg}}{20 \text{ K}}\right) \\ &= \mathbf{0.00381 \text{ K}^{-1}} \end{aligned}$$

and

$$\begin{aligned} \alpha &\cong -\frac{1}{v} \left(\frac{\Delta v}{\Delta P}\right)_{T=30^\circ\text{C}} = -\frac{1}{v} \left(\frac{v_{240\text{kPa}} - v_{180\text{kPa}}}{(240 - 180)\text{kPa}}\right)_{T=30^\circ\text{C}} \\ &= -\frac{1}{0.11874 \text{ m}^3/\text{kg}} \left(\frac{(0.09812 - 0.13248)\text{m}^3/\text{kg}}{60 \text{ kPa}}\right) \\ &= \mathbf{0.00482 \text{ kPa}^{-1}} \end{aligned}$$

12-33 The specific heat difference $c_p - c_v$ for liquid water at 15 MPa and 80°C is to be estimated.

Analysis The specific heat difference $c_p - c_v$ is given as

$$c_p - c_v = -T \left(\frac{\partial v}{\partial T} \right)_P^2 \left(\frac{\partial P}{\partial v} \right)_T$$

Approximating differentials by differences about the specified state,

$$\begin{aligned} c_p - c_v &\cong -T \left(\frac{\Delta v}{\Delta T} \right)_{P=15 \text{ MPa}}^2 \left(\frac{\Delta P}{\Delta v} \right)_{T=80^\circ\text{C}} \\ &= -(80 + 273.15 \text{ K}) \left(\frac{v_{100^\circ\text{C}} - v_{60^\circ\text{C}}}{(100 - 60)^\circ\text{C}} \right)_{P=15 \text{ MPa}}^2 \left(\frac{(20 - 10) \text{ MPa}}{v_{20 \text{ MPa}} - v_{10 \text{ MPa}}} \right)_{T=80^\circ\text{C}} \\ &= -(353.15 \text{ K}) \left(\frac{(0.0010361 - 0.0010105) \text{ m}^3/\text{kg}}{40 \text{ K}} \right)^2 \left(\frac{10,000 \text{ kPa}}{(0.0010199 - 0.0010244) \text{ m}^3/\text{kg}} \right) \\ &= 0.3192 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K} = \mathbf{0.3192 \text{ kJ/kg} \cdot \text{K}} \end{aligned}$$

12-34 The internal energy change of air between two specified states is to be compared for two equations of states.

Assumptions Constant specific heats for air can be used.

Properties For air at the average temperature $(20+300)/2=160^\circ\text{C}=433 \text{ K}$, $c_v = 0.731 \text{ kJ/kg} \cdot \text{K}$ (Table A-2b).

Analysis Solving the equation of state for P gives

$$P = \frac{RT}{v - a}$$

Then,

$$\left(\frac{\partial P}{\partial T} \right)_v = \frac{R}{v - a}$$

Using equation 12-29,

$$du = c_v dT + \left[T \left(\frac{\partial P}{\partial T} \right)_v - P \right] dv$$

Substituting,

$$\begin{aligned} du &= c_v dT + \left(\frac{RT}{v - a} - \frac{RT}{v - a} \right) dv \\ &= c_v dT \end{aligned}$$

Integrating this result between the two states with constant specific heats gives

$$u_2 - u_1 = c_v (T_2 - T_1) = (0.731 \text{ kJ/kg} \cdot \text{K})(300 - 20) \text{ K} = \mathbf{205 \text{ kJ/kg}}$$

The ideal gas model for the air gives

$$du = c_v dT$$

which gives the same answer.

12-35 The enthalpy change of air between two specified states is to be compared for two equations of states.

Assumptions Constant specific heats for air can be used.

Properties For air at the average temperature $(34+420)/2=227^\circ\text{C}=500\text{ K}$, $c_p = 1.018\text{ kJ/kg}\cdot\text{K}$ (Table A-2b).

Analysis Solving the equation of state for ν gives

$$\nu = \frac{RT}{P} + a$$

Then,

$$\left(\frac{\partial \nu}{\partial T}\right)_P = \frac{R}{P}$$

Using equation 12-35,

$$dh = c_p dT + \left[\nu - T \left(\frac{\partial \nu}{\partial T}\right)_P \right] dP$$

Substituting,

$$\begin{aligned} dh &= c_p dT + \left(\frac{RT}{P} + a - \frac{RT}{P} \right) dP \\ &= c_p dT + a dP \end{aligned}$$

Integrating this result between the two states with constant specific heats gives

$$\begin{aligned} h_2 - h_1 &= c_p (T_2 - T_1) + a(P_2 - P_1) \\ &= (1.029\text{ kJ/kg}\cdot\text{K})(420 - 34)\text{K} + (0.01\text{ m}^3/\text{kg})(800 - 100)\text{kPa} \\ &= \mathbf{404.2\text{ kJ/kg}} \end{aligned}$$

For an ideal gas,

$$dh = c_p dT$$

which when integrated gives

$$h_2 - h_1 = c_p (T_2 - T_1) = (1.029\text{ kJ/kg}\cdot\text{K})(420 - 34)\text{K} = \mathbf{397.2\text{ kJ/kg}}$$

12-36 The entropy change of air between two specified states is to be compared for two equations of states.

Assumptions Constant specific heats for air can be used.

Properties For air at the average temperature $(20+300)/2=160^\circ\text{C}=433\text{ K}$, $c_p = 1.018\text{ kJ/kg}\cdot\text{K}$ (Table A-2b) and $R = 0.287\text{ kJ/kg}\cdot\text{K}$ (Table A-1).

Analysis Solving the equation of state for ν gives

$$\nu = \frac{RT}{P} + a$$

Then,

$$\left(\frac{\partial \nu}{\partial T}\right)_P = \frac{R}{P}$$

The entropy differential is

$$\begin{aligned} ds &= c_p \frac{dT}{T} - \left(\frac{\partial \nu}{\partial T}\right)_P dP \\ &= c_p \frac{dT}{T} - R \frac{dP}{P} \end{aligned}$$

which is the same as that of an ideal gas. Integrating this result between the two states with constant specific heats gives

$$\begin{aligned} s_2 - s_1 &= c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \\ &= (1.018\text{ kJ/kg}\cdot\text{K}) \ln \frac{573\text{ K}}{293\text{ K}} - (0.287\text{ kJ/kg}\cdot\text{K}) \ln \frac{600\text{ kPa}}{100\text{ kPa}} \\ &= \mathbf{0.1686\text{ kJ/kg}\cdot\text{K}} \end{aligned}$$

12-37 The internal energy change of helium between two specified states is to be compared for two equations of states.

Properties For helium, $c_v = 3.1156 \text{ kJ/kg}\cdot\text{K}$ (Table A-2a).

Analysis Solving the equation of state for P gives

$$P = \frac{RT}{v - a}$$

Then,

$$\left(\frac{\partial P}{\partial T}\right)_v = \frac{R}{v - a}$$

Using equation 12-29,

$$du = c_v dT + \left[T \left(\frac{\partial P}{\partial T}\right)_v - P \right] dv$$

Substituting,

$$\begin{aligned} du &= c_v dT + \left(\frac{RT}{v - a} - \frac{RT}{v - a} \right) dv \\ &= c_v dT \end{aligned}$$

Integrating this result between the two states gives

$$u_2 - u_1 = c_v (T_2 - T_1) = (3.1156 \text{ kJ/kg}\cdot\text{K})(300 - 20)\text{K} = \mathbf{872.4 \text{ kJ/kg}}$$

The ideal gas model for the helium gives

$$du = c_v dT$$

which gives the same answer.

12-38 The enthalpy change of helium between two specified states is to be compared for two equations of states.

Properties For helium, $c_p = 5.1926 \text{ kJ/kg}\cdot\text{K}$ (Table A-2a).

Analysis Solving the equation of state for ν gives

$$\nu = \frac{RT}{P} + a$$

Then,

$$\left(\frac{\partial \nu}{\partial T}\right)_P = \frac{R}{P}$$

Using equation 12-35,

$$dh = c_p dT + \left[\nu - T \left(\frac{\partial \nu}{\partial T}\right)_P \right] dP$$

Substituting,

$$\begin{aligned} dh &= c_p dT + \left(\frac{RT}{P} + a - \frac{RT}{P} \right) dP \\ &= c_p dT + a dP \end{aligned}$$

Integrating this result between the two states gives

$$\begin{aligned} h_2 - h_1 &= c_p (T_2 - T_1) + a(P_2 - P_1) \\ &= (5.1926 \text{ kJ/kg}\cdot\text{K})(380 - 20)\text{K} + (0.01 \text{ m}^3/\text{kg})(750 - 150)\text{kPa} \\ &= \mathbf{1875 \text{ kJ/kg}} \end{aligned}$$

For an ideal gas,

$$dh = c_p dT$$

which when integrated gives

$$h_2 - h_1 = c_p (T_2 - T_1) = (5.1926 \text{ kJ/kg}\cdot\text{K})(380 - 20)\text{K} = \mathbf{1869 \text{ kJ/kg}}$$

12-39 The entropy change of helium between two specified states is to be compared for two equations of states.

Properties For helium, $c_p = 5.1926 \text{ kJ/kg}\cdot\text{K}$ and $R = 2.0769 \text{ kJ/kg}\cdot\text{K}$ (Table A-2a).

Analysis Solving the equation of state for ν gives

$$\nu = \frac{RT}{P} + a$$

Then,

$$\left(\frac{\partial \nu}{\partial T}\right)_P = \frac{R}{P}$$

The entropy differential is

$$\begin{aligned} ds &= c_p \frac{dT}{T} - \left(\frac{\partial \nu}{\partial T}\right)_P dP \\ &= c_p \frac{dT}{T} - R \frac{dP}{P} \end{aligned}$$

which is the same as that of an ideal gas. Integrating this result between the two states gives

$$\begin{aligned} s_2 - s_1 &= c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \\ &= (5.1926 \text{ kJ/kg}\cdot\text{K}) \ln \frac{573 \text{ K}}{293 \text{ K}} - (2.0769 \text{ kJ/kg}\cdot\text{K}) \ln \frac{600 \text{ kPa}}{100 \text{ kPa}} \\ &= \mathbf{-0.2386 \text{ kJ/kg}\cdot\text{K}} \end{aligned}$$

12-40 General expressions for Δu , Δh , and Δs for a gas whose equation of state is $P(\nu - a) = RT$ for an isothermal process are to be derived.

Analysis (a) A relation for Δu is obtained from the general relation

$$\Delta u = u_2 - u_1 = \int_{T_1}^{T_2} c_\nu dT + \int_{\nu_1}^{\nu_2} \left(T \left(\frac{\partial P}{\partial T} \right)_\nu - P \right) d\nu$$

The equation of state for the specified gas can be expressed as

$$P = \frac{RT}{\nu - a} \longrightarrow \left(\frac{\partial P}{\partial T} \right)_\nu = \frac{R}{\nu - a}$$

Thus,

$$T \left(\frac{\partial P}{\partial T} \right)_\nu - P = \frac{RT}{\nu - a} - P = P - P = 0$$

Substituting,

$$\Delta u = \int_{T_1}^{T_2} c_\nu dT$$

(b) A relation for Δh is obtained from the general relation

$$\Delta h = h_2 - h_1 = \int_{T_1}^{T_2} c_p dT + \int_{P_1}^{P_2} \left(\nu - T \left(\frac{\partial \nu}{\partial T} \right)_P \right) dP$$

The equation of state for the specified gas can be expressed as

$$\nu = \frac{RT}{P} + a \longrightarrow \left(\frac{\partial \nu}{\partial T} \right)_P = \frac{R}{P}$$

Thus,

$$\nu - T \left(\frac{\partial \nu}{\partial T} \right)_P = \nu - T \frac{R}{P} = \nu - (\nu - a) = a$$

Substituting,

$$\Delta h = \int_{T_1}^{T_2} c_p dT + \int_{P_1}^{P_2} a dP = \int_{T_1}^{T_2} c_p dT + a(P_2 - P_1)$$

(c) A relation for Δs is obtained from the general relation

$$\Delta s = s_2 - s_1 = \int_{T_1}^{T_2} \frac{c_p}{T} dT - \int_{P_1}^{P_2} \left(\frac{\partial \nu}{\partial T} \right)_P dP$$

Substituting $(\partial \nu / \partial T)_P = R/T$,

$$\Delta s = \int_{T_1}^{T_2} \frac{c_p}{T} dT - \int_{P_1}^{P_2} \left(\frac{R}{P} \right)_P dP = \int_{T_1}^{T_2} \frac{c_p}{T} dT - R \ln \frac{P_2}{P_1}$$

For an isothermal process $dT = 0$ and these relations reduce to

$$\Delta u = 0, \quad \Delta h = a(P_2 - P_1), \quad \text{and} \quad \Delta s = -R \ln \frac{P_2}{P_1}$$

12-41 General expressions for Δu , Δh , and Δs for a gas that obeys the van der Waals equation of state for an isothermal process are to be derived.

Analysis (a) For an isothermal process $dT = 0$ and the general relation for Δu reduces to

$$\Delta u = u_2 - u_1 = \int_{T_1}^{T_2} c_v dT + \int_{v_1}^{v_2} \left(T \left(\frac{\partial P}{\partial T} \right)_v - P \right) dv = \int_{v_1}^{v_2} \left(T \left(\frac{\partial P}{\partial T} \right)_v - P \right) dv$$

The van der Waals equation of state can be expressed as

$$P = \frac{RT}{v-b} - \frac{a}{v^2} \longrightarrow \left(\frac{\partial P}{\partial T} \right)_v = \frac{R}{v-b}$$

Thus,

$$T \left(\frac{\partial P}{\partial T} \right)_v - P = \frac{RT}{v-b} - \frac{RT}{v-b} + \frac{a}{v^2} = \frac{a}{v^2}$$

Substituting,

$$\Delta u = \int_{v_1}^{v_2} \frac{a}{v^2} dv = a \left(\frac{1}{v_1} - \frac{1}{v_2} \right)$$

(b) The enthalpy change Δh is related to Δu through the relation

$$\Delta h = \Delta u + P_2 v_2 - P_1 v_1$$

where

$$Pv = \frac{RTv}{v-b} - \frac{a}{v}$$

Thus,

$$P_2 v_2 - P_1 v_1 = RT \left(\frac{v_2}{v_2-b} - \frac{v_1}{v_1-b} \right) + a \left(\frac{1}{v_1} - \frac{1}{v_2} \right)$$

Substituting,

$$\Delta h = 2a \left(\frac{1}{v_1} - \frac{1}{v_2} \right) + RT \left(\frac{v_2}{v_2-b} - \frac{v_1}{v_1-b} \right)$$

(c) For an isothermal process $dT = 0$ and the general relation for Δs reduces to

$$\Delta s = s_2 - s_1 = \int_{T_1}^{T_2} \frac{c_v}{T} dT + \int_{v_1}^{v_2} \left(\frac{\partial P}{\partial T} \right)_v dv = \int_{v_1}^{v_2} \left(\frac{\partial P}{\partial T} \right)_v dv$$

Substituting $(\partial P/\partial T)_v = R/(v-b)$,

$$\Delta s = \int_{v_1}^{v_2} \frac{R}{v-b} dv = R \ln \frac{v_2-b}{v_1-b}$$

12-42 Expressions for the specific heat difference $c_p - c_v$ for three substances are to be derived.

Analysis The general relation for the specific heat difference $c_p - c_v$ is

$$c_p - c_v = -T \left(\frac{\partial v}{\partial T} \right)_P^2 \left(\frac{\partial P}{\partial v} \right)_T$$

(a) For an ideal gas $Pv = RT$. Then,

$$v = \frac{RT}{P} \longrightarrow \left(\frac{\partial v}{\partial T} \right)_P = \frac{R}{P}$$

$$P = \frac{RT}{v} \longrightarrow \left(\frac{\partial P}{\partial v} \right)_T = -\frac{RT}{v^2} = -\frac{P}{v}$$

Substituting,

$$c_p - c_v = -T \left(-\frac{P}{v} \right)^2 \left(\frac{R}{P} \right) = \frac{TR}{Pv} R = R$$

(b) For a van der Waals gas $\left(P + \frac{a}{v^2} \right) (v - b) = RT$. Then,

$$T = \frac{1}{R} \left(P + \frac{a}{v^2} \right) (v - b) \longrightarrow \left(\frac{\partial T}{\partial v} \right)_P = \frac{1}{R} \left(-\frac{2a}{v^3} \right) (v - b) + \frac{1}{R} \left(P + \frac{a}{v^2} \right)$$

$$= \frac{2a(b - v)}{Rv^3} + \frac{T}{v - b}$$

Inverting,

$$\left(\frac{\partial v}{\partial T} \right)_P = \frac{1}{\frac{2a(b - v)}{Rv^3} + \frac{T}{v - b}}$$

Also,

$$P = \frac{RT}{v - b} - \frac{a}{v^2} \longrightarrow \left(\frac{\partial P}{\partial v} \right)_T = -\frac{RT}{(v - b)^2} + \frac{2a}{v^3}$$

Substituting,

$$c_p - c_v = T \left(\frac{1}{\frac{2a(b - v)}{Rv^3} + \frac{T}{v - b}} \right)^2 \left(-\frac{RT}{(v - b)^2} + \frac{2a}{v^3} \right)$$

(c) For an incompressible substance $v = \text{constant}$ and thus $(\partial v / \partial T)_P = 0$. Therefore,

$$c_p - c_v = \mathbf{0}$$

12-43 It is to be shown that $c_p - c_v = T \left(\frac{\partial P}{\partial T} \right)_v \left(\frac{\partial v}{\partial T} \right)_p$.

Analysis We begin by taking the entropy to be a function of specific volume and temperature. The differential of the entropy is then

$$ds = \left(\frac{\partial s}{\partial T} \right)_v dT + \left(\frac{\partial s}{\partial v} \right)_T dv$$

Substituting $\left(\frac{\partial s}{\partial T} \right)_v = \frac{c_v}{T}$ from Eq. 12-28 and the third Maxwell equation changes this to

$$ds = \frac{c_v}{T} dT + \left(\frac{\partial P}{\partial T} \right)_v dv$$

Taking the entropy to be a function of pressure and temperature,

$$ds = \left(\frac{\partial s}{\partial T} \right)_p dT + \left(\frac{\partial s}{\partial P} \right)_T dP$$

Combining this result with $\left(\frac{\partial s}{\partial T} \right)_p = \frac{c_p}{T}$ from Eq. 12-34 and the fourth Maxwell equation produces

$$ds = \frac{c_p}{T} dT - \left(\frac{\partial v}{\partial T} \right)_p dP$$

Equating the two previous ds expressions and solving the result for the specific heat difference,

$$(c_p - c_v)dT = T \left(\frac{\partial v}{\partial T} \right)_p dP + \left(\frac{\partial P}{\partial T} \right)_v dv$$

Taking the pressure to be a function of temperature and volume,

$$dP = \left(\frac{\partial P}{\partial T} \right)_v dT + \left(\frac{\partial P}{\partial v} \right)_T dv$$

When this is substituted into the previous expression, the result is

$$(c_p - c_v)dT = T \left(\frac{\partial v}{\partial T} \right)_p \left(\frac{\partial P}{\partial T} \right)_v dT + T \left[\left(\frac{\partial v}{\partial T} \right)_p \left(\frac{\partial P}{\partial v} \right)_T \left(\frac{\partial P}{\partial T} \right)_v \right] dv$$

According to the cyclic relation, the term in the bracket is zero. Then, canceling the common dT term,

$$c_p - c_v = T \left(\frac{\partial P}{\partial T} \right)_v \left(\frac{\partial v}{\partial T} \right)_p$$

12-44 It is to be proven that the definition for temperature $T = (\partial u / \partial s)_v$ reduces the net entropy change of two constant-volume systems filled with simple compressible substances to zero as the two systems approach thermal equilibrium.

Analysis The two constant-volume systems form an isolated system shown here

For the isolated system

$$dS_{\text{tot}} = dS_A + dS_B \geq 0$$

Assume $S = S(u, v)$

Then,

$$ds = \left(\frac{\partial s}{\partial u} \right)_v du + \left(\frac{\partial s}{\partial v} \right)_u dv$$

Since $v = \text{const.}$ and $dv = 0$,

$$ds = \left(\frac{\partial s}{\partial u} \right)_v du$$

and from the definition of temperature from the problem statement,

$$\frac{du}{(\partial u / \partial s)_v} = \frac{du}{T}$$

Then,

$$dS_{\text{tot}} = m_A \frac{du_A}{T_A} + m_B \frac{du_B}{T_B}$$

The first law applied to the isolated system yields

$$E_{\text{in}} - E_{\text{out}} = dU \\ 0 = dU \longrightarrow m_A du_A + m_B du_B = 0 \longrightarrow m_B du_B = -m_A du_A$$

Now, the entropy change may be expressed as

$$dS_{\text{tot}} = m_A du_A \left(\frac{1}{T_A} - \frac{1}{T_B} \right) = m_A du_A \left(\frac{T_B - T_A}{T_A T_B} \right)$$

As the two systems approach thermal equilibrium,

$$\lim dS_{\text{tot}} = 0 \\ T_A \rightarrow T_B$$

12-45 Relations for the volume expansivity β and the isothermal compressibility α for an ideal gas and for a gas whose equation of state is $P(\nu - a) = RT$ are to be obtained.

Analysis The volume expansivity and isothermal compressibility are expressed as

$$\beta = \frac{1}{\nu} \left(\frac{\partial \nu}{\partial T} \right)_P \quad \text{and} \quad \alpha = -\frac{1}{\nu} \left(\frac{\partial \nu}{\partial P} \right)_T$$

(a) For an ideal gas $\nu = RT/P$. Thus,

$$\begin{aligned} \left(\frac{\partial \nu}{\partial T} \right)_P &= \frac{R}{P} \quad \longrightarrow \quad \beta = \frac{1}{\nu} \frac{R}{P} = \frac{1}{T} \\ \left(\frac{\partial \nu}{\partial P} \right)_T &= -\frac{RT}{P^2} = -\frac{\nu}{P} \quad \longrightarrow \quad \alpha = -\frac{1}{\nu} \left(-\frac{\nu}{P} \right) = \frac{1}{P} \end{aligned}$$

(b) For a gas whose equation of state is $\nu = RT/P + a$,

$$\begin{aligned} \left(\frac{\partial \nu}{\partial T} \right)_P &= \frac{R}{P} \quad \longrightarrow \quad \beta = \frac{1}{\nu} \frac{R}{P} = \frac{R}{RT + aP} \\ \left(\frac{\partial \nu}{\partial P} \right)_T &= -\frac{RT}{P^2} = -\frac{\nu - a}{P} \quad \longrightarrow \quad \alpha = -\frac{1}{\nu} \left(-\frac{\nu - a}{P} \right) = \frac{\nu - a}{P\nu} \end{aligned}$$

12-46 An expression for the isothermal compressibility of a substance whose equation of state is $P = \frac{RT}{\nu - b} - \frac{a}{\nu(\nu + b)T^{1/2}}$

is to be derived.

Analysis The definition for the isothermal compressibility is

$$\alpha = -\frac{1}{\nu} \left(\frac{\partial \nu}{\partial P} \right)_T$$

The derivative is

$$\left(\frac{\partial P}{\partial \nu} \right)_T = -\frac{RT}{(\nu - b)^2} + \frac{a}{T^{1/2}} \frac{2\nu + b}{\nu^2(\nu + b)^2}$$

Substituting,

$$\alpha = -\frac{1}{\nu} \left(\frac{\partial \nu}{\partial P} \right)_T = -\frac{1}{\nu} \left(\frac{1}{-\frac{RT}{(\nu - b)^2} + \frac{a}{T^{1/2}} \frac{2\nu + b}{\nu^2(\nu + b)^2}} \right) = -\frac{1}{-\frac{RT\nu}{(\nu - b)^2} + \frac{a}{T^{1/2}} \frac{2\nu + b}{(\nu + b)^2}}$$

12-47 An expression for the volume expansivity of a substance whose equation of state is $P = \frac{RT}{\nu - b} - \frac{a}{\nu^2 T}$ is to be derived.

Analysis The definition for volume expansivity is

$$\beta = \frac{1}{\nu} \left(\frac{\partial \nu}{\partial T} \right)_P$$

According to the cyclic relation,

$$\left(\frac{\partial \nu}{\partial T} \right)_P \left(\frac{\partial P}{\partial \nu} \right)_T \left(\frac{\partial T}{\partial P} \right)_\nu = -1$$

which on rearrangement becomes

$$\left(\frac{\partial \nu}{\partial T} \right)_P = - \frac{\left(\frac{\partial P}{\partial T} \right)_\nu}{\left(\frac{\partial P}{\partial \nu} \right)_T}$$

Proceeding to perform the differentiations gives

$$\left(\frac{\partial P}{\partial T} \right)_\nu = \frac{R}{\nu - b} + \frac{a}{\nu^2 T^2}$$

and

$$\left(\frac{\partial P}{\partial \nu} \right)_T = - \frac{RT}{(\nu - b)^2} + \frac{2a}{\nu^3 T}$$

Substituting these results into the definition of the volume expansivity produces

$$\beta = - \frac{1}{\nu} \frac{\frac{R}{\nu - b} + \frac{a}{\nu^2 T^2}}{- \frac{RT}{(\nu - b)^2} + \frac{2a}{\nu^3 T}}$$

12-48 It is to be shown that $\beta = \alpha \left(\frac{\partial P}{\partial T} \right)_v$.

Analysis The definition for the volume expansivity is

$$\beta = \frac{1}{v} \left(\frac{\partial v}{\partial T} \right)_P$$

The definition for the isothermal compressibility is

$$\alpha = -\frac{1}{v} \left(\frac{\partial v}{\partial P} \right)_T$$

According to the cyclic relation,

$$\left(\frac{\partial v}{\partial T} \right)_P \left(\frac{\partial P}{\partial v} \right)_T \left(\frac{\partial T}{\partial P} \right)_v = -1$$

which on rearrangement becomes

$$\left(\frac{\partial v}{\partial T} \right)_P = - \left(\frac{\partial v}{\partial P} \right)_T \left(\frac{\partial P}{\partial T} \right)_v$$

When this is substituted into the definition of the volume expansivity, the result is

$$\begin{aligned} \beta &= -\frac{1}{v} \left(\frac{\partial v}{\partial P} \right)_T \left(\frac{\partial P}{\partial T} \right)_v \\ &= -\alpha \left(\frac{\partial P}{\partial T} \right)_v \end{aligned}$$

12-49 It is to be demonstrated that $k = \frac{c_p}{c_v} = -\frac{\nu\alpha}{(\partial\nu/\partial P)_s}$.

Analysis The relations for entropy differential are

$$ds = c_v \frac{dT}{T} + \left(\frac{\partial P}{\partial T}\right)_\nu d\nu$$

$$ds = c_p \frac{dT}{T} - \left(\frac{\partial \nu}{\partial T}\right)_P dP$$

For fixed s , these basic equations reduce to

$$c_v \frac{dT}{T} = -\left(\frac{\partial P}{\partial T}\right)_\nu d\nu$$

$$c_p \frac{dT}{T} = \left(\frac{\partial \nu}{\partial T}\right)_P dP$$

Also, when s is fixed,

$$\frac{\partial \nu}{\partial P} = \left(\frac{\partial \nu}{\partial P}\right)_s$$

Forming the specific heat ratio from these expressions gives

$$k = -\frac{\left(\frac{\partial \nu}{\partial T}\right)_P \left(\frac{\partial T}{\partial P}\right)_\nu}{\left(\frac{\partial \nu}{\partial P}\right)_s}$$

The cyclic relation is

$$\left(\frac{\partial \nu}{\partial T}\right)_P \left(\frac{\partial P}{\partial \nu}\right)_T \left(\frac{\partial T}{\partial P}\right)_\nu = -1$$

Solving this for the numerator of the specific heat ratio expression and substituting the result into this numerator produces

$$k = \frac{\left(\frac{\partial \nu}{\partial P}\right)_T}{\left(\frac{\partial \nu}{\partial P}\right)_s} = -\frac{\nu\alpha}{\left(\frac{\partial \nu}{\partial P}\right)_s}$$

12-50 The Helmholtz function of a substance has the form $a = -RT \ln \frac{v}{v_0} - cT_0 \left(1 - \frac{T}{T_0} + \frac{T}{T_0} \ln \frac{T}{T_0} \right)$. It is to be shown how to obtain P , h , s , c_v , and c_p from this expression.

Analysis Taking the Helmholtz function to be a function of temperature and specific volume yields

$$da = \left(\frac{\partial a}{\partial T} \right)_v dT + \left(\frac{\partial a}{\partial v} \right)_T dv$$

while the applicable Helmholtz equation is

$$da = -Pd v - s dT$$

Equating the coefficients of the two results produces

$$P = - \left(\frac{\partial a}{\partial v} \right)_T$$

$$s = - \left(\frac{\partial a}{\partial T} \right)_v$$

Taking the indicated partial derivatives of the Helmholtz function given in the problem statement reduces these expressions to

$$P = \frac{RT}{v}$$

$$s = R \ln \frac{v}{v_0} + c \ln \frac{T}{T_0}$$

The definition of the enthalpy ($h = u + Pv$) and Helmholtz function ($a = u - Ts$) may be combined to give

$$h = u + Pv$$

$$= a + Ts + Pv$$

$$= a - T \left(\frac{\partial a}{\partial T} \right)_v - v \left(\frac{\partial a}{\partial v} \right)_T$$

$$= -RT \ln \frac{v}{v_0} - cT_0 \left(1 - \frac{T}{T_0} + \frac{T}{T_0} \ln \frac{T}{T_0} \right) + RT \ln \frac{v}{v_0} - cT \ln \frac{T}{T_0} + RT$$

$$= cT_0 + cT + RT$$

According to $\left(\frac{\partial s}{\partial T} \right)_v = \frac{c_v}{T}$ given in the text (Eq. 12-28),

$$c_v = T \left(\frac{\partial s}{\partial T} \right)_v = T \frac{c}{T} = c$$

The preceding expression for the temperature indicates that the equation of state for the substance is the same as that of an ideal gas. Then,

$$c_p = R + c_v = R + c$$

12-51 It is to be shown that the enthalpy of an ideal gas is a function of temperature only and that for an incompressible substance it also depends on pressure.

Analysis The change in enthalpy is expressed as

$$dh = c_p dT + \left(\nu - T \left(\frac{\partial \nu}{\partial T} \right)_P \right) dP$$

For an ideal gas $\nu = RT/P$. Then,

$$\nu - T \left(\frac{\partial \nu}{\partial T} \right)_P = \nu - T \left(\frac{R}{P} \right) = \nu - \nu = 0$$

Thus,

$$dh = c_p dT$$

To complete the proof we need to show that c_p is not a function of P either. This is done with the help of the relation

$$\left(\frac{\partial c_p}{\partial P} \right)_T = -T \left(\frac{\partial^2 \nu}{\partial T^2} \right)_P$$

For an ideal gas,

$$\left(\frac{\partial \nu}{\partial T} \right)_P = \frac{R}{P} \quad \text{and} \quad \left(\frac{\partial^2 \nu}{\partial T^2} \right)_P = \left(\frac{\partial (R/P)}{\partial T} \right)_P = 0$$

Thus,

$$\left(\frac{\partial c_p}{\partial P} \right)_T = 0$$

Therefore we conclude that the enthalpy of an ideal gas is a function of temperature only.

For an incompressible substance $\nu = \text{constant}$ and thus $\partial \nu / \partial T = 0$. Then,

$$dh = c_p dT + \nu dP$$

Therefore we conclude that the enthalpy of an incompressible substance is a function of temperature and pressure.

The Joule-Thomson Coefficient

12-52C It represents the variation of temperature with pressure during a throttling process.

12-53C The line that passes through the peak points of the constant enthalpy lines on a T - P diagram is called the inversion line. The maximum inversion temperature is the highest temperature a fluid can be cooled by throttling.

12-54C No. The temperature may even increase as a result of throttling.

12-55C Yes.

12-56C No. Helium is an ideal gas and $h = h(T)$ for ideal gases. Therefore, the temperature of an ideal gas remains constant during a throttling ($h = \text{constant}$) process.

12-57E  The Joule-Thomson coefficient of nitrogen at two states is to be estimated.

Analysis (a) The enthalpy of nitrogen at 120 psia and 350 R is, from EES, $h = 84.88$ Btu/lbm. Approximating differentials by differences about the specified state, the Joule-Thomson coefficient is expressed as

$$\mu = \left(\frac{\partial T}{\partial P} \right)_h \cong \left(\frac{\Delta T}{\Delta P} \right)_{h=84.88 \text{ Btu/lbm}}$$

Considering a throttling process from 130 psia to 110 psia at $h = 84.88$ Btu/lbm, the Joule-Thomson coefficient is determined to be

$$\mu = \left(\frac{T_{110 \text{ psia}} - T_{130 \text{ psia}}}{(110 - 130) \text{ psia}} \right)_{h=84.88 \text{ Btu/lbm}} = \frac{(349.40 - 350.60) \text{ R}}{(110 - 130) \text{ psia}} = \mathbf{0.0599 \text{ R/psia}}$$

(b) The enthalpy of nitrogen at 1200 psia and 700 R is, from EES, $h = 170.14$ Btu/lbm. Approximating differentials by differences about the specified state, the Joule-Thomson coefficient is expressed as

$$\mu = \left(\frac{\partial T}{\partial P} \right)_h \cong \left(\frac{\Delta T}{\Delta P} \right)_{h=170.14 \text{ Btu/lbm}}$$

Considering a throttling process from 1210 psia to 1190 psia at $h = 170.14$ Btu/lbm, the Joule-Thomson coefficient is determined to be

$$\mu = \left(\frac{T_{1190 \text{ psia}} - T_{1210 \text{ psia}}}{(1190 - 1210) \text{ psia}} \right)_{h=170.14 \text{ Btu/lbm}} = \frac{(699.91 - 700.09) \text{ R}}{(1190 - 1210) \text{ psia}} = \mathbf{0.00929 \text{ R/psia}}$$

12-58E Problem 12-57E is reconsidered. The Joule-Thompson coefficient for nitrogen over the pressure range 100 to 1500 psia at the enthalpy values 100, 175, and 225 Btu/lbm is to be plotted.

Analysis The problem is solved using EES, and the results are tabulated and plotted below.

```

Gas$ = 'Nitrogen'
{P_ref=120 [psia]
T_ref=350 [R]
P= P_ref}
h=100 [Btu/lbm]
{h=enthalpy(Gas$, T=T_ref, P=P_ref)}
dP = 10 [psia]
T = temperature(Gas$, P=P, h=h)
P[1] = P + dP
P[2] = P - dP
T[1] = temperature(Gas$, P=P[1], h=h)
T[2] = temperature(Gas$, P=P[2], h=h)
Mu = DELTAT/DELTAP "Approximate the differential by differences about the state at h=const."
DELTAT=T[2]-T[1]
DELTAP=P[2]-P[1]

```

h = 225 Btu/lbm	
P [psia]	μ [R/psia]
100	0.004573
275	0.00417
450	0.003781
625	0.003405
800	0.003041
975	0.002688
1150	0.002347
1325	0.002015
1500	0.001694

12-59 Steam is throttled slightly from 2 MPa and 500°C. It is to be determined if the temperature of the steam will increase, decrease, or remain the same during this process.

Analysis The enthalpy of steam at 2 MPa and $T = 500^\circ\text{C}$ is $h = 3468.3$ kJ/kg. Now consider a throttling process from this state to 1.8 MPa, which is the next lowest pressure listed in the tables. The temperature of the steam at the end of this throttling process will be

$$\left. \begin{array}{l} P = 1.8 \text{ MPa} \\ h = 3468.3 \text{ kJ/kg} \end{array} \right\} T_2 = 499.0^\circ\text{C}$$

Therefore, the temperature will **decrease**.

12-60 The Joule-Thomson coefficient of steam at two states is to be estimated.

Analysis (a) The enthalpy of steam at 3 MPa and 300°C is $h = 2994.3$ kJ/kg. Approximating differentials by differences about the specified state, the Joule-Thomson coefficient is expressed as

$$\mu = \left(\frac{\partial T}{\partial P} \right)_h \cong \left(\frac{\Delta T}{\Delta P} \right)_{h=2994.3 \text{ kJ/kg}}$$

Considering a throttling process from 3.5 MPa to 2.5 MPa at $h = 2994.3$ kJ/kg, the Joule-Thomson coefficient is determined to be

$$\mu = \left(\frac{T_{3.5 \text{ MPa}} - T_{2.5 \text{ MPa}}}{(3.5 - 2.5) \text{ MPa}} \right)_{h=2994.3 \text{ kJ/kg}} = \frac{(306.3 - 294)^\circ\text{C}}{(3.5 - 2.5) \text{ MPa}} = \mathbf{12.3^\circ\text{C/MPa}}$$

(b) The enthalpy of steam at 6 MPa and 500°C is $h = 3423.1$ kJ/kg. Approximating differentials by differences about the specified state, the Joule-Thomson coefficient is expressed as

$$\mu = \left(\frac{\partial T}{\partial P} \right)_h \cong \left(\frac{\Delta T}{\Delta P} \right)_{h=3423.1 \text{ kJ/kg}}$$

Considering a throttling process from 7.0 MPa to 5.0 MPa at $h = 3423.1$ kJ/kg, the Joule-Thomson coefficient is determined to be

$$\mu = \left(\frac{T_{7.0 \text{ MPa}} - T_{5.0 \text{ MPa}}}{(7.0 - 5.0) \text{ MPa}} \right)_{h=3423.1 \text{ kJ/kg}} = \frac{(504.8 - 495.1)^\circ\text{C}}{(7.0 - 5.0) \text{ MPa}} = \mathbf{4.9^\circ\text{C/MPa}}$$

12-61E The Joule-Thomson coefficient of refrigerant-134a at a given state is to be estimated.

Analysis The Joule-Thomson coefficient is defined as

$$\mu = \left(\frac{\partial T}{\partial P} \right)_h$$

We use a finite difference approximation as

$$\mu \cong \frac{T_2 - T_1}{P_2 - P_1} \quad (\text{at constant enthalpy})$$

At the given state (we call it state 1), the enthalpy of R-134a is

$$\left. \begin{array}{l} P_1 = 40 \text{ psia} \\ T_1 = 60^\circ\text{F} \end{array} \right\} h_1 = 113.80 \text{ Btu/lbm} \quad (\text{Table A - 13E})$$

The second state will be selected for a pressure of 30 psia. At this pressure and the same enthalpy, we have

$$\left. \begin{array}{l} P_2 = 30 \text{ psia} \\ h_2 = h_1 = 113.80 \text{ kJ/kg} \end{array} \right\} T_2 = 56.83^\circ\text{F} \quad (\text{Table A - 13E})$$

Substituting,

$$\mu \cong \frac{T_2 - T_1}{P_2 - P_1} = \frac{(56.83 - 60)\text{R}}{(30 - 40)\text{psia}} = \mathbf{0.317\text{R/psia}}$$

12-62 It is to be demonstrated that the Joule-Thomson coefficient is given by $\mu = \frac{T^2}{c_p} \left(\frac{\partial(\nu/T)}{\partial T} \right)_P$.

Analysis From Eq. 12-52 of the text,

$$c_p = \frac{1}{\mu} \left[T \left(\frac{\partial \nu}{\partial T} \right)_P - \nu \right]$$

Expanding the partial derivative of ν/T produces

$$\left(\frac{\partial \nu/T}{\partial T} \right)_P = \frac{1}{T} \left(\frac{\partial \nu}{\partial T} \right)_P - \frac{\nu}{T^2}$$

When this is multiplied by T^2 , the right-hand side becomes the same as the bracketed quantity above. Then,

$$\mu = \frac{T^2}{c_p} \left(\frac{\partial(\nu/T)}{\partial T} \right)_P$$

12-63 The equation of state of a gas is given to be $P(\nu - a) = RT$. It is to be determined if it is possible to cool this gas by throttling.

Analysis The equation of state of this gas can be expressed as

$$\nu = \frac{RT}{P} + a \longrightarrow \left(\frac{\partial \nu}{\partial T} \right)_P = \frac{R}{P}$$

Substituting into the Joule-Thomson coefficient relation,

$$\mu = -\frac{1}{c_p} \left(\nu - T \left(\frac{\partial \nu}{\partial T} \right)_P \right) = -\frac{1}{c_p} \left(\nu - T \frac{R}{P} \right) = -\frac{1}{c_p} (\nu - \nu + a) = -\frac{a}{c_p} < 0$$

Therefore, this gas **cannot** be cooled by throttling since μ is always a negative quantity.

12-64 Relations for the Joule-Thomson coefficient and the inversion temperature for a gas whose equation of state is $(P+a/v^2)v=RT$ are to be obtained.

Analysis The equation of state of this gas can be expressed as

$$T = \frac{v}{R} \left(P + \frac{a}{v^2} \right) \longrightarrow \left(\frac{\partial T}{\partial v} \right)_P = \frac{v}{R} \left(-\frac{2a}{v^3} \right) + \frac{1}{R} \left(P + \frac{a}{v^2} \right) = -\frac{2av}{Rv^2} + \frac{T}{v} = \frac{RTv - 2a}{Rv^2}$$

Substituting into the Joule-Thomson coefficient relation,

$$\mu = -\frac{1}{c_p} \left(v - T \left(\frac{\partial v}{\partial T} \right)_P \right) = -\frac{1}{c_p} \left(v - \frac{RTv^2}{RTv - 2a} \right) = -\frac{2av}{c_p(2a - RTv)}$$

The temperature at $\mu = 0$ is the inversion temperature,

$$\mu = -\frac{2av}{c_p(2a - RTv)} = 0 \longrightarrow v = 0$$

Thus the line of $v = 0$ is the inversion line. Since it is not physically possible to have $v = 0$, this gas does not have an inversion line.

The dh , du , and ds of Real Gases

12-65C As P_R approaches zero, the gas approaches ideal gas behavior. As a result, the deviation from ideal gas behavior diminishes.

12-66C So that a single chart can be used for all gases instead of a single particular gas.

12-67 The enthalpy of nitrogen at 175 K and 8 MPa is to be determined using data from the ideal-gas nitrogen table and the generalized enthalpy departure chart.

Analysis (a) From the ideal gas table of nitrogen (Table A-18) we read

$$h = 5083.8 \text{ kJ/kmol} = \mathbf{181.48 \text{ kJ/kg}} \quad (M_{\text{N}_2} = 28.013 \text{ kg/kmol})$$

at the specified temperature. This value involves 44.4% error.

(b) The enthalpy departure of nitrogen at the specified state is determined from the generalized chart to be

and

$$\left. \begin{aligned} T_R &= \frac{T}{T_{\text{cr}}} = \frac{175}{126.2} = 1.387 \\ P_R &= \frac{P}{P_{\text{cr}}} = \frac{8}{3.39} = 2.360 \end{aligned} \right\} \longrightarrow Z_h = \frac{(\bar{h}_{\text{ideal}} - \bar{h})_{T,P}}{R_u T_{\text{cr}}} = 1.6$$

Thus,

$$\bar{h} = \bar{h}_{\text{ideal}} - Z_h R_u T_{\text{cr}} = 5083.8 - [(1.6)(8.314)(126.2)] = 3405.0 \text{ kJ/kmol}$$

or,

$$h = \frac{\bar{h}}{M} = \frac{3405.0 \text{ kJ/kmol}}{28.013 \text{ kg/kmol}} = \mathbf{121.6 \text{ kJ/kg}} \quad (3.1\% \text{ error})$$

12-68E The enthalpy of nitrogen at 400 R and 2000 psia is to be determined using data from the ideal-gas nitrogen table and the generalized enthalpy departure chart.

Analysis (a) From the ideal gas table of nitrogen (Table A-18E) we read

$$h = 2777.0 \text{ Btu/lbmol} = \mathbf{99.18 \text{ Btu/lbm}} \quad (M_{\text{N}_2} = 28 \text{ lbm/lbmol})$$

at the specified temperature. This value involves 44.2% error.

(b) The enthalpy departure of nitrogen at the specified state is determined from the generalized chart to be (Fig. A-29)

$$\left. \begin{aligned} T_R &= \frac{T}{T_{\text{cr}}} = \frac{400}{227.1} = 1.761 \\ P_R &= \frac{P}{P_{\text{cr}}} = \frac{2000}{492} = 4.065 \end{aligned} \right\} \longrightarrow Z_h = \frac{(\bar{h}_{\text{ideal}} - \bar{h})_{T,P}}{R_u T_{\text{cr}}} = 1.18$$

Thus,

$$\bar{h} = \bar{h}_{\text{ideal}} - Z_h R_u T_{\text{cr}} = 2777.0 - [(1.18)(1.986)(227.1)] = 2244.8 \text{ Btu/lbmol}$$

or,

$$h = \frac{\bar{h}}{M} = \frac{2244.8 \text{ Btu/lbmol}}{28 \text{ lbm/lbmol}} = \mathbf{80.17 \text{ Btu/lbm}} \quad (54.9\% \text{ error})$$

N₂
400 R
2000 psia

12-69 The enthalpy and entropy changes of CO₂ during a process are to be determined assuming ideal gas behavior and using generalized charts.

Analysis (a) Using data from the ideal gas property table of CO₂ (Table A-20),

$$(\bar{h}_2 - \bar{h}_1)_{\text{ideal}} = \bar{h}_{2,\text{ideal}} - \bar{h}_{1,\text{ideal}} = 8,697 - 7,627 = 1,070 \text{ kJ/kmol}$$

$$(\bar{s}_2 - \bar{s}_1)_{\text{ideal}} = s_2^\circ - s_1^\circ - R_u \ln \frac{P_2}{P_1} = 211.376 - 207.337 - 8.314 \times \ln \frac{12}{7} \\ = -0.442 \text{ kJ/kmol} \cdot \text{K}$$

$$(h_2 - h_1)_{\text{ideal}} = \frac{(\bar{h}_2 - \bar{h}_1)_{\text{ideal}}}{M} = \frac{1,070 \text{ kJ/kmol}}{44 \text{ kg/kmol}} = \mathbf{24.32 \text{ kJ/kg}}$$

$$(s_2 - s_1)_{\text{ideal}} = \frac{(\bar{s}_2 - \bar{s}_1)_{\text{ideal}}}{M} = \frac{-0.442 \text{ kJ/kmol}}{44 \text{ kg/kmol}} = \mathbf{-0.0100 \text{ kJ/kg} \cdot \text{K}}$$

(b) The enthalpy and entropy departures of CO₂ at the specified states are determined from the generalized charts to be (Figs. A-29, A-30)

$$\left. \begin{aligned} T_{R1} &= \frac{T_1}{T_{\text{cr}}} = \frac{250}{304.2} = 0.822 \\ P_{R1} &= \frac{P_1}{P_{\text{cr}}} = \frac{7}{7.39} = 0.947 \end{aligned} \right\} \longrightarrow Z_{h1} = 5.5 \text{ and } Z_{s1} = 5.3$$

and

$$\left. \begin{aligned} T_{R2} &= \frac{T_2}{T_{\text{cr}}} = \frac{280}{304.2} = 0.920 \\ P_{R2} &= \frac{P_2}{P_{\text{cr}}} = \frac{12}{7.39} = 1.624 \end{aligned} \right\} \longrightarrow Z_{h2} = 5.0 \text{ and } Z_{s2} = 4.2$$

Thus,

$$h_2 - h_1 = RT_{\text{cr}}(Z_{h1} - Z_{h2}) + (h_2 - h_1)_{\text{ideal}} = (0.1889)(304.2)(5.5 - 5.0) + 24.32 = \mathbf{53.05 \text{ kJ/kg}}$$

$$s_2 - s_1 = R(Z_{s1} - Z_{s2}) + (s_2 - s_1)_{\text{ideal}} = (0.1889)(5.3 - 4.2) - 0.010 = \mathbf{0.198 \text{ kJ/kg} \cdot \text{K}}$$

12-70E The enthalpy and entropy changes of water vapor during a change of state are to be determined using the departure charts and the property tables.

Properties The properties of water are (Table A-1E)

$$M = 18.015 \text{ lbm/lbmol}, T_{\text{cr}} = 1164.8 \text{ R}, P_{\text{cr}} = 3200 \text{ psia}$$

Analysis (a) The pressure of water vapor during this process is

$$P_1 = P_2 = P_{\text{sat @ } 400^\circ\text{F}} = 247.26 \text{ psia}$$

Using data from the ideal gas property table of water vapor (Table A-23),

$$(\bar{h}_2 - \bar{h}_1)_{\text{ideal}} = \bar{h}_{2,\text{ideal}} - \bar{h}_{1,\text{ideal}} = 10,354.9 - 6895.6 = 3459.3 \text{ Btu/lbmol}$$

and

$$(\bar{s}_2 - \bar{s}_1)_{\text{ideal}} = s_2^\circ - s_1^\circ - R_u \ln \frac{P_2}{P_1} = 52.212 - 48.916 - 0 = 3.296 \text{ Btu/lbmol} \cdot \text{R}$$

The enthalpy and entropy departures of water vapor at the specified states are determined from the generalized charts to be (Figs. A-29, A-30 or from EES-We used EES.)

$$\left. \begin{aligned} T_{R1} &= \frac{T_1}{T_{\text{cr}}} = \frac{860}{1164.8} = 0.7380 \\ P_{R1} &= \frac{P_1}{P_{\text{cr}}} = \frac{247.26}{3200} = 0.07727 \end{aligned} \right\} \longrightarrow Z_{h1} = 0.1342 \text{ and } Z_{s1} = 0.1171$$

and

$$\left. \begin{aligned} T_{R2} &= \frac{T_2}{T_{\text{cr}}} = \frac{1260}{1164.8} = 1.081 \\ P_{R2} &= \frac{P_2}{P_{\text{cr}}} = \frac{680.56}{3200} = 0.07727 \end{aligned} \right\} \longrightarrow Z_{h2} = 0.07213 \text{ and } Z_{s2} = 0.04595$$

The enthalpy and entropy changes per mole basis are

$$\begin{aligned} \bar{h}_2 - \bar{h}_1 &= (\bar{h}_2 - \bar{h}_1)_{\text{ideal}} - R_u T_{\text{cr}} (Z_{h2} - Z_{h1}) \\ &= 3459.3 - (1.9858)(1164.8)(0.07213 - 0.1342) = 3602.9 \text{ kJ/kmol} \end{aligned}$$

$$\begin{aligned} \bar{s}_2 - \bar{s}_1 &= (\bar{s}_2 - \bar{s}_1)_{\text{ideal}} - R_u (Z_{s2} - Z_{s1}) \\ &= 3.296 - (1.9858)(0.04595 - 0.1171) = 3.4373 \text{ Btu/lbmol} \cdot \text{R} \end{aligned}$$

The enthalpy and entropy changes per mass basis are

$$\begin{aligned} h_2 - h_1 &= \frac{\bar{h}_2 - \bar{h}_1}{M} = \frac{3602.9 \text{ Btu/lbmol}}{18.015 \text{ lbm/lbmol}} = \mathbf{200.0 \text{ Btu/lbm}} \\ s_2 - s_1 &= \frac{\bar{s}_2 - \bar{s}_1}{M} = \frac{3.4373 \text{ Btu/lbmol} \cdot \text{K}}{18.015 \text{ lbm/lbmol}} = \mathbf{0.1908 \text{ Btu/lbm} \cdot \text{R}} \end{aligned}$$

(b) The inlet and exit state properties of water are

$$\left. \begin{aligned} T_1 &= 400^\circ\text{F} \\ x_1 &= 1 \end{aligned} \right\} \begin{aligned} h_1 &= 1201.4 \text{ Btu/lbm} \\ s_1 &= 1.5279 \text{ Btu/lbm} \cdot \text{R} \end{aligned} \quad (\text{Table A-4E})$$

$$\left. \begin{aligned} P_2 &= 247.26 \text{ psia} \\ T_2 &= 800^\circ\text{F} \end{aligned} \right\} \begin{aligned} h_2 &= 1423.6 \text{ Btu/lbm} \\ s_2 &= 1.7418 \text{ Btu/lbm} \cdot \text{R} \end{aligned} \quad (\text{from EES})$$

The enthalpy and entropy changes are

$$\begin{aligned} h_2 - h_1 &= 1423.6 - 1201.4 = \mathbf{222.2 \text{ Btu/lbm}} \\ s_2 - s_1 &= 1.7418 - 1.5279 = \mathbf{0.2139 \text{ Btu/lbm} \cdot \text{R}} \end{aligned}$$

12-71 The enthalpy and entropy changes of water vapor during a change of state are to be determined using the departure charts and the property tables.

Properties The properties of water are (Table A-1)

$$M = 18.015 \text{ kg/kmol}, T_{\text{cr}} = 647.1 \text{ K}, P_{\text{cr}} = 22.06 \text{ MPa}$$

Analysis Using data from the ideal gas property table of water vapor (Table A-23),

$$(\bar{h}_2 - \bar{h}_1)_{\text{ideal}} = \bar{h}_{2,\text{ideal}} - \bar{h}_{1,\text{ideal}} = 23,082 - 30,754 = -7672 \text{ kJ/kmol}$$

and

$$(\bar{s}_2 - \bar{s}_1)_{\text{ideal}} = s_2^\circ - s_1^\circ - R_u \ln \frac{P_2}{P_1} = 217.141 - 227.109 - 8.314 \times \ln \frac{500}{1000} = -4.2052 \text{ kJ/kmol} \cdot \text{K}$$

The enthalpy and entropy departures of water vapor at the specified states are determined from the generalized charts to be (Figs. A-29, A-30 or from EES)

$$\left. \begin{aligned} T_{R1} &= \frac{T_1}{T_{\text{cr}}} = \frac{873}{647.1} = 1.349 \\ P_{R1} &= \frac{P_1}{P_{\text{cr}}} = \frac{1}{22.06} = 0.0453 \end{aligned} \right\} \longrightarrow Z_{h1} = 0.0288 \text{ and } Z_{s1} = 0.0157$$

and

$$\left. \begin{aligned} T_{R2} &= \frac{T_2}{T_{\text{cr}}} = \frac{673}{647.1} = 1.040 \\ P_{R2} &= \frac{P_2}{P_{\text{cr}}} = \frac{0.5}{22.06} = 0.0227 \end{aligned} \right\} \longrightarrow Z_{h2} = 0.0223 \text{ and } Z_{s2} = 0.0146$$

The enthalpy and entropy changes per mole basis are

$$\begin{aligned} \bar{h}_2 - \bar{h}_1 &= (\bar{h}_2 - \bar{h}_1)_{\text{ideal}} - R_u T_{\text{cr}} (Z_{h2} - Z_{h1}) \\ &= -7672 - (8.314)(647.1)(0.0223 - 0.0288) = -7637 \text{ kJ/kmol} \end{aligned}$$

$$\begin{aligned} \bar{s}_2 - \bar{s}_1 &= (\bar{s}_2 - \bar{s}_1)_{\text{ideal}} - R_u (Z_{s2} - Z_{s1}) \\ &= -4.2052 - (8.314)(0.0146 - 0.0157) = -4.1961 \text{ kJ/kmol} \cdot \text{K} \end{aligned}$$

The enthalpy and entropy changes per mass basis are

$$\begin{aligned} h_2 - h_1 &= \frac{\bar{h}_2 - \bar{h}_1}{M} = \frac{-7637 \text{ kJ/kmol}}{18.015 \text{ kg/kmol}} = \mathbf{-423.9 \text{ kJ/kg}} \\ s_2 - s_1 &= \frac{\bar{s}_2 - \bar{s}_1}{M} = \frac{-4.1961 \text{ kJ/kmol} \cdot \text{K}}{18.015 \text{ kg/kmol}} = \mathbf{-0.2329 \text{ kJ/kg} \cdot \text{K}} \end{aligned}$$

The inlet and exit state properties of water vapor from Table A-6 are

$$\left. \begin{aligned} P_1 &= 1000 \text{ kPa} \\ T_1 &= 600^\circ\text{C} \end{aligned} \right\} \begin{aligned} h_1 &= 3698.6 \text{ kJ/kg} \\ s_1 &= 8.0311 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

$$\left. \begin{aligned} P_2 &= 500 \text{ kPa} \\ T_2 &= 400^\circ\text{C} \end{aligned} \right\} \begin{aligned} h_2 &= 3272.4 \text{ kJ/kg} \\ s_2 &= 7.7956 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

The enthalpy and entropy changes are

$$\begin{aligned} h_2 - h_1 &= 3272.4 - 3698.6 = \mathbf{-426.2 \text{ kJ/kg}} \\ s_2 - s_1 &= 7.7956 - 8.0311 = \mathbf{-0.2355 \text{ kJ/kg} \cdot \text{K}} \end{aligned}$$

12-72 Methane is compressed adiabatically by a steady-flow compressor. The required power input to the compressor is to be determined using the generalized charts.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis The steady-flow energy balance equation for this compressor can be expressed as

$$\begin{aligned}\dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}}^{\phi^0(\text{steady})} = 0 \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \dot{W}_{\text{C,in}} + \dot{m}h_1 &= \dot{m}h_2 \\ \dot{W}_{\text{C,in}} &= \dot{m}(h_2 - h_1)\end{aligned}$$

The enthalpy departures of CH_4 at the specified states are determined from the generalized charts to be (Fig. A-29)

$$\left. \begin{aligned}T_{R1} &= \frac{T_1}{T_{\text{cr}}} = \frac{263}{191.1} = 1.376 \\ P_{R1} &= \frac{P_1}{P_{\text{cr}}} = \frac{0.8}{4.64} = 0.172\end{aligned} \right\} \longrightarrow Z_{h1} = 0.075$$

and

$$\left. \begin{aligned}T_{R2} &= \frac{T_2}{T_{\text{cr}}} = \frac{448}{191.1} = 2.34 \\ P_{R2} &= \frac{P_2}{P_{\text{cr}}} = \frac{6}{4.64} = 1.29\end{aligned} \right\} \longrightarrow Z_{h2} = 0.25$$

Thus,

$$\begin{aligned}h_2 - h_1 &= RT_{\text{cr}}(Z_{h1} - Z_{h2}) + (h_2 - h_1)_{\text{ideal}} \\ &= (0.5182)(191.1)(0.075 - 0.25) + 2.2537(175 - (-10)) \\ &= 399.6 \text{ kJ/kg}\end{aligned}$$

Substituting,

$$\dot{W}_{\text{C,in}} = (0.33 \text{ kg/s})(399.6 \text{ kJ/kg}) = \mathbf{132 \text{ kW}}$$

12-73 Carbon dioxide passes through an adiabatic nozzle. The exit velocity is to be determined using the generalized enthalpy departure chart.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible. 3 The nozzle is adiabatic and thus heat transfer is negligible

Properties The gas constant of CO_2 is $0.1889 \text{ kJ/kg}\cdot\text{K}$ (Table A-1).

Analysis The steady-flow energy balance equation for this nozzle can be expressed as

$$\begin{aligned}\dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}}^{\phi^0(\text{steady})} = 0 \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ h_1 + (V_1^2/2)^{\phi^0} &= h_2 + (V_2^2/2) \\ V_2 &= \sqrt{2(h_1 - h_2)}\end{aligned}$$

The enthalpy departures of CO_2 at the specified states are determined from the generalized enthalpy departure chart to be

$$\left. \begin{aligned} T_{R1} &= \frac{T_1}{T_{\text{cr}}} = \frac{450}{304.2} = 1.48 \\ P_{R1} &= \frac{P_1}{P_{\text{cr}}} = \frac{8}{7.39} = 1.08 \end{aligned} \right\} \longrightarrow Z_{h1} = 0.55$$

and

$$\left. \begin{aligned} T_{R2} &= \frac{T_2}{T_{\text{cr}}} = \frac{350}{304.2} = 1.15 \\ P_{R2} &= \frac{P_2}{P_{\text{cr}}} = \frac{2}{7.39} = 0.27 \end{aligned} \right\} \longrightarrow Z_{h2} = 0.20$$

Thus,

$$\begin{aligned} h_2 - h_1 &= RT_{\text{cr}}(Z_{h1} - Z_{h2}) + (h_2 - h_1)_{\text{ideal}} \\ &= (0.1889)(304.2)(0.55 - 0.2) + (11,351 - 15,483)/44 = -73.8 \text{ kJ/kg} \end{aligned}$$

Substituting,

$$V_2 = \sqrt{2(73.8 \text{ kJ/kg}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = \mathbf{384 \text{ m/s}}$$

12-74 Problem 12-73 is reconsidered. the exit velocity to the nozzle assuming ideal gas behavior, the generalized chart data, and EES data for carbon dioxide are to be compared.

Analysis The problem is solved using EES, and the results are given below.

12-75E Oxygen is to be adiabatically and reversibly expanded in a nozzle. The exit velocity is to be determined using the departure charts and treating the oxygen as an ideal gas with temperature variable specific heats.

Properties The properties of oxygen are (Table A-1)

$$M = 31.999 \text{ lbm/lbmol}, R = 0.06206 \text{ Btu/lbm} \cdot \text{R}, T_{\text{cr}} = 278.6 \text{ R}, P_{\text{cr}} = 736 \text{ psia}$$

Analysis The temperature at the exit state may be determined by the fact that the process is isentropic and the molar entropy change between the inlet and exit is zero. From the entropy change equation for an ideal gas with variable specific heats:

$$\begin{aligned} (\bar{s}_2 - \bar{s}_1)_{\text{ideal}} &= 0 \\ s_2^\circ - s_1^\circ &= R_u \ln \frac{P_2}{P_1} = (1.9858) \ln \frac{70}{200} = -2.085 \text{ Btu/lbmol} \cdot \text{R} \end{aligned}$$

Then from Table A-19E,

$$\begin{aligned} T_1 &= 1060 \text{ R} \longrightarrow \bar{h}_{1,\text{ideal}} = 7543.6 \text{ Btu/lbmol}, s_1^\circ = 53.921 \text{ Btu/lbmol} \cdot \text{R} \\ s_2^\circ &= s_1^\circ - 2.085 = 53.921 - 2.085 = 51.836 \text{ Btu/lbmol} \cdot \text{R} \\ s_2^\circ &= 51.836 \text{ Btu/lbmol} \cdot \text{R} \longrightarrow T_2 = 802 \text{ R}, \bar{h}_{2,\text{ideal}} = 5614.1 \text{ Btu/lbmol} \end{aligned}$$

The enthalpy change per mole basis is

$$(\bar{h}_2 - \bar{h}_1)_{\text{ideal}} = \bar{h}_{2,\text{ideal}} - \bar{h}_{1,\text{ideal}} = 5614.1 - 7543.6 = -1929.5 \text{ Btu/lbmol}$$

The enthalpy change per mass basis is

$$(h_2 - h_1)_{\text{ideal}} = \frac{(\bar{h}_2 - \bar{h}_1)_{\text{ideal}}}{M} = \frac{-1929.5 \text{ Btu/lbmol}}{31.999 \text{ lbm/lbmol}} = -60.30 \text{ Btu/lbm}$$

An energy balance on the nozzle gives

$$\begin{aligned} \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \dot{m}(h_1 + V_1^2 / 2) &= \dot{m}(h_2 + V_2^2 / 2) \\ h_1 + V_1^2 / 2 &= h_2 + V_2^2 / 2 \end{aligned}$$

Solving for the exit velocity,

$$V_2 = \left[V_1^2 + 2(h_1 - h_2) \right]^{0.5} = \left[(0 \text{ ft/s})^2 + 2(60.30 \text{ Btu/lbm}) \left(\frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right) \right]^{0.5} = \mathbf{1738 \text{ ft/s}}$$

The enthalpy departures of oxygen at the specified states are determined from the generalized charts to be (Fig. A-29 or from EES)

$$\left. \begin{aligned} T_{R1} &= \frac{T_1}{T_{\text{cr}}} = \frac{1060}{278.6} = 3.805 \\ P_{R1} &= \frac{P_1}{P_{\text{cr}}} = \frac{200}{736} = 0.272 \end{aligned} \right\} Z_{h1} = 0.000759 \quad \left. \begin{aligned} T_{R2} &= \frac{T_2}{T_{\text{cr}}} = \frac{802}{278.6} = 2.879 \\ P_{R2} &= \frac{P_2}{P_{\text{cr}}} = \frac{70}{736} = 0.0951 \end{aligned} \right\} Z_{h2} = 0.00894$$

The enthalpy change is

$$\begin{aligned} h_2 - h_1 &= (h_2 - h_1)_{\text{ideal}} - RT_{\text{cr}}(Z_{h2} - Z_{h1}) \\ &= -60.30 \text{ Btu/lbm} - (0.06206 \text{ Btu/lbm} \cdot \text{R})(278.6 \text{ R})(0.00894 - 0.000759) \\ &= -60.44 \text{ Btu/lbm} \end{aligned}$$

The exit velocity is

$$V_2 = \left[V_1^2 + 2(h_1 - h_2) \right]^{0.5} = \left[(0 \text{ ft/s})^2 + 2(60.44 \text{ Btu/lbm}) \left(\frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right) \right]^{0.5} = \mathbf{1740 \text{ ft/s}}$$

12-76  Propane is compressed isothermally by a piston-cylinder device. The work done and the heat transfer are to be determined using the generalized charts.

Assumptions **1** The compression process is quasi-equilibrium. **2** Kinetic and potential energy changes are negligible.

Analysis (a) The enthalpy departure and the compressibility factors of propane at the initial and the final states are determined from the generalized charts to be (Figs. A-29, A-15)

$$\left. \begin{aligned} T_{R1} &= \frac{T_1}{T_{cr}} = \frac{373}{370} = 1.008 \\ P_{R1} &= \frac{P_1}{P_{cr}} = \frac{1}{4.26} = 0.235 \end{aligned} \right\} \longrightarrow Z_{h1} = 0.28 \text{ and } Z_1 = 0.92$$

and

$$\left. \begin{aligned} T_{R2} &= \frac{T_2}{T_{cr}} = \frac{373}{370} = 1.008 \\ P_{R2} &= \frac{P_2}{P_{cr}} = \frac{4}{4.26} = 0.939 \end{aligned} \right\} \longrightarrow Z_{h2} = 1.8 \text{ and } Z_2 = 0.50$$

Treating propane as a real gas with $Z_{\text{avg}} = (Z_1 + Z_2)/2 = (0.92 + 0.50)/2 = 0.71$,

$$Pv = ZRT \cong Z_{\text{avg}}RT = C = \text{constant}$$

Then the boundary work becomes

$$\begin{aligned} w_{b,\text{in}} &= -\int_1^2 Pd\nu = -\int_1^2 \frac{C}{\nu} d\nu = -C \ln \frac{\nu_2}{\nu_1} = Z_{\text{avg}}RT \ln \frac{Z_2 RT / P_2}{Z_1 RT / P_1} = -Z_{\text{ave}}RT \ln \frac{Z_2 P_1}{Z_1 P_2} \\ &= -(0.71)(0.1885 \text{ kJ/kg} \cdot \text{K})(373 \text{ K}) \ln \frac{(0.50)(1)}{(0.92)(4)} \\ &= \mathbf{99.6 \text{ kJ/kg}} \end{aligned}$$

Also,

$$\begin{aligned} h_2 - h_1 &= RT_{cr}(Z_{h1} - Z_{h2}) + (h_2 - h_1)_{\text{ideal}} = (0.1885)(370)(0.28 - 1.8) + 0 = -106 \text{ kJ/kg} \\ u_2 - u_1 &= (h_2 - h_1) - R(Z_2 T_2 - Z_1 T_1) = -106 - (0.1885)[(0.5)(373) - (0.92)(373)] = -76.5 \text{ kJ/kg} \end{aligned}$$

Then the heat transfer for this process is determined from the closed system energy balance to be

$$\begin{aligned} E_{\text{in}} - E_{\text{out}} &= \Delta E_{\text{system}} \\ q_{\text{in}} + w_{b,\text{in}} &= \Delta u = u_2 - u_1 \\ q_{\text{in}} &= (u_2 - u_1) - w_{b,\text{in}} = -76.5 - 99.6 = -176.1 \text{ kJ/kg} \quad \rightarrow \quad q_{\text{out}} = 176.1 \text{ kJ/kg} \end{aligned}$$

12-77 Problem 12-76 is reconsidered. This problem is to be extended to compare the solutions based on the ideal gas assumption, generalized chart data and real fluid (EES) data. Also, the solution is to be extended to carbon dioxide, nitrogen and methane.

Analysis The problem is solved using EES, and the solution is given below.

```

12-78 Propane is compressed isothermally by a piston-cylinder device. The exergy destruction associated with this process is to be determined.

Assumptions 1 The compression process is quasi-equilibrium. 2 Kinetic and potential energy changes are negligible.

Properties The gas constant of propane is $R = 0.1885 \text{ kJ/kg}\cdot\text{K}$ (Table A-1).

Analysis The exergy destruction is determined from its definition $x_{\text{destroyed}} = T_0 s_{\text{gen}}$ where the entropy generation is determined from an entropy balance on the contents of the cylinder. It gives

$$S_{\text{in}} - S_{\text{out}} + S_{\text{gen}} = \Delta S_{\text{system}}$$

$$-\frac{Q_{\text{out}}}{T_{b,\text{surr}}} + S_{\text{gen}} = m(s_2 - s_1) \rightarrow s_{\text{gen}} = (s_2 - s_1) + \frac{q_{\text{out}}}{T_{\text{surr}}}$$

where

$$\Delta s_{\text{sys}} = s_2 - s_1 = R(Z_{s1} - Z_{s2}) + (s_2 - s_1)_{\text{ideal}}$$

$$(s_2 - s_1)_{\text{ideal}} = c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} = 0 - 0.1885 \ln \frac{4}{1} = -0.261 \text{ kJ/kg}\cdot\text{K}$$

$$\left. \begin{aligned} T_{R1} &= \frac{T_1}{T_{\text{cr}}} = \frac{373}{370} = 1.008 \\ P_{R1} &= \frac{P_1}{P_{\text{cr}}} = \frac{1}{4.26} = 0.235 \end{aligned} \right\} \longrightarrow Z_{s1} = 0.21$$

and

$$\left. \begin{aligned} T_{R2} &= \frac{T_2}{T_{\text{cr}}} = \frac{373}{370} = 1.008 \\ P_{R2} &= \frac{P_2}{P_{\text{cr}}} = \frac{4}{4.26} = 0.939 \end{aligned} \right\} \longrightarrow Z_{s2} = 1.5$$

Thus,

$$\Delta s_{\text{sys}} = s_2 - s_1 = R(Z_{s1} - Z_{s2}) + (s_2 - s_1)_{\text{ideal}} = (0.1885)(0.21 - 1.5) - 0.261 = -0.504 \text{ kJ/kg}\cdot\text{K}$$

and

$$x_{\text{destroyed}} = T_0 s_{\text{gen}} = T_0 \left((s_2 - s_1) + \frac{q_{\text{out}}}{T_{\text{surr}}} \right)$$

$$= (298 \text{ K}) \left(-0.504 + \frac{176.1 \text{ kJ/kg}}{298 \text{ K}} \right) \text{ kJ/kg}\cdot\text{K}$$

$$= \mathbf{25.9 \text{ kJ/kg}}$$

12-79 A paddle-wheel placed in a well-insulated rigid tank containing oxygen is turned on. The final pressure in the tank and the paddle-wheel work done during this process are to be determined.

Assumptions 1 The tank is well-insulated and thus heat transfer is negligible. 2 Kinetic and potential energy changes are negligible.

Properties The gas constant of O_2 is $R = 0.2598 \text{ kJ/kg}\cdot\text{K}$ (Table A-1).

Analysis (a) For this problem, we use critical properties, compressibility factor, and enthalpy departure factors in EES. The compressibility factor of oxygen at the initial state is determined from EES to be

$$\left. \begin{aligned} T_{R1} &= \frac{T_1}{T_{cr}} = \frac{175}{154.6} = 1.13 \\ P_{R1} &= \frac{P_1}{P_{cr}} = \frac{6}{5.043} = 1.19 \end{aligned} \right\} \longrightarrow Z_1 = 0.682 \text{ and } Z_{h1} = 1.33$$

Then,

$$Pv = ZRT \longrightarrow v_1 = \frac{(0.682)(0.2598 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(175 \text{ K})}{6000 \text{ kPa}} = 0.00516 \text{ m}^3/\text{kg}$$

$$m = \frac{V}{v_1} = \frac{0.05 \text{ m}^3}{0.00516 \text{ m}^3/\text{kg}} = 9.68 \text{ kg}$$

The specific volume of oxygen remains constant during this process, $v_2 = v_1$. Thus,

$$\left. \begin{aligned} T_{R2} &= \frac{T_2}{T_{cr}} = \frac{225}{154.8} = 1.46 \\ v_{R2} &= \frac{v_2}{RT_{cr}/P_{cr}} = \frac{0.00516 \text{ m}^3/\text{kg}}{(0.2598 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(154.6 \text{ K})/(5043 \text{ kPa})} = 0.649 \end{aligned} \right\} \begin{aligned} Z_2 &= 0.853 \\ Z_{h2} &= 1.09 \\ P_{R2} &= 1.91 \end{aligned}$$

$$P_2 = P_{R2} P_{cr} = (1.91)(5043) = \mathbf{9652 \text{ kPa}}$$

(b) The energy balance relation for this closed system can be expressed as

$$E_{in} - E_{out} = \Delta E_{system}$$

$$W_{in} = \Delta U = m(u_2 - u_1)$$

$$W_{in} = m[h_2 - h_1 - (P_2 v_2 - P_1 v_1)] = m[h_2 - h_1 - R(Z_2 T_2 - Z_1 T_1)]$$

where

$$\begin{aligned} h_2 - h_1 &= RT_{cr}(Z_{h1} - Z_{h2}) + (h_2 - h_1)_{ideal} \\ &= (0.2598)(154.6)(1.33 - 1.09) + 52.96 \\ &= 62.51 \text{ kJ/kg} \end{aligned}$$

Substituting,

$$W_{in} = (9.68 \text{ kg})[62.51 - (0.2598 \text{ kJ/kg}\cdot\text{K})\{(0.853)(225) - (0.682)(175)\}\text{K}] = \mathbf{423 \text{ kJ}}$$

Discussion The following routine in EES is used to get the solution above. Reading values from Fig. A-15 and A-29 together with properties in the book could yield different results.

Review Problems

12-80 The relations for Δu , Δh , and Δs of a gas that obeys the equation of state $(P+a/v^2)v = RT$ for an isothermal process are to be derived.

Analysis (a) For an isothermal process $dT = 0$ and the general relation for Δu reduces to

$$\Delta u = u_2 - u_1 = \int_{T_1}^{T_2} c_v dT + \int_{v_1}^{v_2} \left(T \left(\frac{\partial P}{\partial T} \right)_v - P \right) dv = \int_{v_1}^{v_2} \left(T \left(\frac{\partial P}{\partial T} \right)_v - P \right) dv$$

For this gas the equation of state can be expressed as

$$P = \frac{RT}{v} - \frac{a}{v^2} \longrightarrow \left(\frac{\partial P}{\partial T} \right)_v = \frac{R}{v}$$

Thus,

$$T \left(\frac{\partial P}{\partial T} \right)_v - P = \frac{RT}{v} - \frac{RT}{v} + \frac{a}{v^2} = \frac{a}{v^2}$$

Substituting,

$$\Delta u = \int_{v_1}^{v_2} \frac{a}{v^2} dv = a \left(\frac{1}{v_1} - \frac{1}{v_2} \right)$$

(b) The enthalpy change Δh is related to Δu through the relation

$$\Delta h = \Delta u + P_2 v_2 - P_1 v_1$$

where

$$Pv = RT - \frac{a}{v}$$

Thus,

$$P_2 v_2 - P_1 v_1 = \left(RT - \frac{a}{v_2} \right) - \left(RT - \frac{a}{v_1} \right) = a \left(\frac{1}{v_1} - \frac{1}{v_2} \right)$$

Substituting,

$$\Delta h = 2a \left(\frac{1}{v_1} - \frac{1}{v_2} \right)$$

(c) For an isothermal process $dT = 0$ and the general relation for Δs reduces to

$$\Delta s = s_2 - s_1 = \int_{T_1}^{T_2} \frac{c_v}{T} dT + \int_{v_1}^{v_2} \left(\frac{\partial P}{\partial T} \right)_v dv = \int_{v_1}^{v_2} \left(\frac{\partial P}{\partial T} \right)_v dv$$

Substituting $(\partial P/\partial T)_v = R/v$,

$$\Delta s = \int_{v_1}^{v_2} \frac{R}{v} dv = R \ln \frac{v_2}{v_1}$$

12-81 It is to be shown that the slope of a constant-pressure line on an h - s diagram is constant in the saturation region and increases with temperature in the superheated region.

Analysis For $P = \text{constant}$, $dP = 0$ and the given relation reduces to $dh = Tds$, which can also be expressed as

$$\left(\frac{\partial h}{\partial s}\right)_P = T$$

Thus the slope of the $P = \text{constant}$ lines on an h - s diagram is equal to the temperature.

(a) In the saturation region, $T = \text{constant}$ for $P = \text{constant}$ lines, and the slope remains constant.

(b) In the superheat region, the slope increases with increasing temperature since the slope is equal temperature.

12-82 It is to be shown that

$$c_v = -T \left(\frac{\partial v}{\partial T}\right)_s \left(\frac{\partial P}{\partial T}\right)_v \quad \text{and} \quad c_p = T \left(\frac{\partial P}{\partial T}\right)_s \left(\frac{\partial v}{\partial T}\right)_P$$

Analysis Using the definition of c_v ,

$$c_v = T \left(\frac{\partial s}{\partial T}\right)_v = T \left(\frac{\partial s}{\partial P}\right)_v \left(\frac{\partial P}{\partial T}\right)_v$$

Substituting the first Maxwell relation $\left(\frac{\partial s}{\partial P}\right)_v = -\left(\frac{\partial v}{\partial T}\right)_s$,

$$c_v = -T \left(\frac{\partial v}{\partial T}\right)_s \left(\frac{\partial P}{\partial T}\right)_v$$

Using the definition of c_p ,

$$c_p = T \left(\frac{\partial s}{\partial T}\right)_P = T \left(\frac{\partial s}{\partial v}\right)_P \left(\frac{\partial v}{\partial T}\right)_P$$

Substituting the second Maxwell relation $\left(\frac{\partial s}{\partial v}\right)_P = \left(\frac{\partial P}{\partial T}\right)_s$,

$$c_p = T \left(\frac{\partial P}{\partial T}\right)_s \left(\frac{\partial v}{\partial T}\right)_P$$

12-83 It is to be proven that for a simple compressible substance $\left(\frac{\partial s}{\partial \nu}\right)_u = \frac{P}{T}$.

Analysis The proof is simply obtained as

$$\left(\frac{\partial s}{\partial \nu}\right)_u = \frac{-\left(\frac{\partial u}{\partial \nu}\right)_s}{\left(\frac{\partial u}{\partial s}\right)_\nu} = -\frac{-P}{T} = \frac{P}{T}$$

12-84 It is to be proven by using the definitions of pressure and temperature, $T = \left(\frac{\partial u}{\partial s}\right)_\nu$ and $P = -\left(\frac{\partial u}{\partial \nu}\right)_s$ that for ideal gases, the development of the constant-pressure specific heat yields $\left(\frac{\partial h}{\partial P}\right)_T = 0$

Analysis The definition for enthalpy is

$$h = u + P\nu$$

Then,

$$\left(\frac{\partial h}{\partial P}\right)_T = \left(\frac{\partial u}{\partial P}\right)_T + P\left(\frac{\partial \nu}{\partial P}\right)_T + \nu\left(\frac{\partial P}{\partial P}\right)_T$$

Assume $u = u(s, \nu)$

Then,

$$\begin{aligned} du &= \left(\frac{\partial u}{\partial s}\right)_\nu ds + \left(\frac{\partial u}{\partial \nu}\right)_s d\nu \\ \left(\frac{\partial u}{\partial P}\right)_T &= \left(\frac{\partial u}{\partial s}\right)_\nu \left(\frac{\partial s}{\partial P}\right)_T + \left(\frac{\partial u}{\partial \nu}\right)_s \left(\frac{\partial \nu}{\partial P}\right)_T \\ \left(\frac{\partial u}{\partial P}\right)_T &= T \left[-\left(\frac{\partial \nu}{\partial T}\right)_P \right] - P \left(\frac{\partial \nu}{\partial P}\right)_T = -(T + P) \left(\frac{\partial \nu}{\partial P}\right)_T \\ \left(\frac{\partial h}{\partial P}\right)_T &= -(T + P) \left(\frac{\partial \nu}{\partial P}\right)_T + P \left(\frac{\partial \nu}{\partial P}\right)_T + \nu = -T \left(\frac{\partial \nu}{\partial P}\right)_T + \nu \end{aligned}$$

For ideal gases

$$\nu = \frac{RT}{P} \quad \text{and} \quad \left(\frac{\partial \nu}{\partial P}\right)_T = -\frac{R}{P}$$

Then,

$$\left(\frac{\partial h}{\partial P}\right)_T = -\frac{TR}{P} + \nu = -\nu + \nu = 0$$

12-85 It is to be shown that the position of the Joule-Thompson coefficient inversion curve on the T - P plane is given by $(\partial Z/\partial T)_P = 0$.

Analysis The inversion curve is the locus of the points at which the Joule-Thompson coefficient μ is zero,

$$\mu = \frac{1}{c_p} \left(T \left(\frac{\partial \nu}{\partial T} \right)_P - \nu \right) = 0$$

which can also be written as

$$T \left(\frac{\partial \nu}{\partial T} \right)_P - \frac{ZRT}{P} = 0 \quad (a)$$

since it is given that

$$\nu = \frac{ZRT}{P} \quad (b)$$

Taking the derivative of (b) with respect to T holding P constant gives

$$\left(\frac{\partial \nu}{\partial T} \right)_P = \left(\frac{\partial (ZRT/P)}{\partial T} \right)_P = \frac{R}{P} \left(T \left(\frac{\partial Z}{\partial T} \right)_P + Z \right)$$

Substituting in (a),

$$\begin{aligned} \frac{TR}{P} \left(T \left(\frac{\partial Z}{\partial T} \right)_P + Z \right) - \frac{ZRT}{P} &= 0 \\ T \left(\frac{\partial Z}{\partial T} \right)_P + Z - Z &= 0 \\ \left(\frac{\partial Z}{\partial T} \right)_P &= 0 \end{aligned}$$

which is the desired relation.

12-86 It is to be shown that $\frac{d\nu}{\nu} = \beta dT - \alpha dP$. Also, a relation is to be obtained for the ratio of specific volumes ν_2/ν_1 as a homogeneous system undergoes a process from state 1 to state 2.

Analysis We take $\nu = \nu(P, T)$. Its total differential is

$$d\nu = \left(\frac{\partial \nu}{\partial T}\right)_P dT + \left(\frac{\partial \nu}{\partial P}\right)_T dP$$

Dividing by ν ,

$$\frac{d\nu}{\nu} = \frac{1}{\nu} \left(\frac{\partial \nu}{\partial T}\right)_P dT + \frac{1}{\nu} \left(\frac{\partial \nu}{\partial P}\right)_T dP$$

Using the definitions of α and β ,

$$\frac{d\nu}{\nu} = \beta dT - \alpha dP$$

Taking α and β to be constants, integration from 1 to 2 yields

$$\ln \frac{\nu_2}{\nu_1} = \beta(T_2 - T_1) - \alpha(P_2 - P_1)$$

which is the desired relation.

12-87 It is to be shown that $\frac{d\nu}{\nu} = \beta dT - \alpha dP$. Also, a relation is to be obtained for the ratio of specific volumes ν_2/ν_1 as a homogeneous system undergoes an isobaric process from state 1 to state 2.

Analysis We take $\nu = \nu(P, T)$. Its total differential is

$$d\nu = \left(\frac{\partial \nu}{\partial T}\right)_P dT + \left(\frac{\partial \nu}{\partial P}\right)_T dP$$

which, for a constant pressure process, reduces to

$$d\nu = \left(\frac{\partial \nu}{\partial T}\right)_P dT$$

Dividing by ν ,

$$\frac{d\nu}{\nu} = \frac{1}{\nu} \left(\frac{\partial \nu}{\partial T}\right)_P dT$$

Using the definition of β ,

$$\frac{d\nu}{\nu} = \beta dT$$

Taking β to be a constant, integration from 1 to 2 yields

$$\ln \frac{\nu_2}{\nu_1} = \beta(T_2 - T_1)$$

or

$$\frac{\nu_2}{\nu_1} = \exp[\beta(T_2 - T_1)]$$

which is the desired relation.

12-88 It is to be shown that for an isentropic expansion or compression process $P\nu^k = \text{constant}$. It is also to be shown that the isentropic expansion exponent k reduces to the specific heat ratio c_p/c_ν for an ideal gas.

Analysis We note that $ds = 0$ for an isentropic process. Taking $s = s(P, \nu)$, the total differential ds can be expressed as

$$ds = \left(\frac{\partial s}{\partial P}\right)_\nu dP + \left(\frac{\partial s}{\partial \nu}\right)_P d\nu = 0 \quad (a)$$

We now substitute the Maxwell relations below into (a)

$$\left(\frac{\partial s}{\partial P}\right)_\nu = -\left(\frac{\partial \nu}{\partial T}\right)_s \quad \text{and} \quad \left(\frac{\partial s}{\partial \nu}\right)_P = \left(\frac{\partial P}{\partial T}\right)_s$$

to get

$$-\left(\frac{\partial \nu}{\partial T}\right)_s dP + \left(\frac{\partial P}{\partial T}\right)_s d\nu = 0$$

Rearranging,

$$dP - \left(\frac{\partial T}{\partial \nu}\right)_s \left(\frac{\partial P}{\partial T}\right)_s d\nu = 0 \longrightarrow dP - \left(\frac{\partial P}{\partial \nu}\right)_s d\nu = 0$$

$$\text{Dividing by } P, \quad \frac{dP}{P} - \frac{1}{P} \left(\frac{\partial P}{\partial \nu}\right)_s d\nu = 0 \quad (b)$$

We now define isentropic expansion exponent k as

$$k = -\frac{\nu}{P} \left(\frac{\partial P}{\partial \nu}\right)_s$$

Substituting in (b),

$$\frac{dP}{P} + k \frac{d\nu}{\nu} = 0$$

Taking k to be a constant and integrating,

$$\ln P + k \ln \nu = \text{constant} \longrightarrow \ln P\nu^k = \text{constant}$$

Thus,

$$P\nu^k = \text{constant}$$

To show that $k = c_p/c_\nu$ for an ideal gas, we write the cyclic relations for the following two groups of variables:

$$(s, T, \nu) \longrightarrow \left(\frac{\partial s}{\partial T}\right)_\nu \left(\frac{\partial \nu}{\partial s}\right)_T \left(\frac{\partial T}{\partial \nu}\right)_s = -1 \longrightarrow \frac{c_\nu}{T} \left(\frac{\partial \nu}{\partial s}\right)_T \left(\frac{\partial T}{\partial \nu}\right)_s = -1 \quad (c)$$

$$(s, T, P) \longrightarrow \left(\frac{\partial s}{\partial T}\right)_P \left(\frac{\partial P}{\partial s}\right)_T \left(\frac{\partial T}{\partial P}\right)_s = -1 \longrightarrow \frac{c_p}{T} \left(\frac{\partial P}{\partial s}\right)_T \left(\frac{\partial T}{\partial P}\right)_s = -1 \quad (d)$$

where we used the relations

$$c_\nu = T \left(\frac{\partial s}{\partial T}\right)_\nu \quad \text{and} \quad c_p = T \left(\frac{\partial s}{\partial T}\right)_P$$

Setting Eqs. (c) and (d) equal to each other,

$$\frac{c_p}{T} \left(\frac{\partial P}{\partial s}\right)_T \left(\frac{\partial T}{\partial P}\right)_s = \frac{c_\nu}{T} \left(\frac{\partial \nu}{\partial s}\right)_T \left(\frac{\partial T}{\partial \nu}\right)_s$$

or,

$$\frac{c_p}{c_\nu} = \left(\frac{\partial s}{\partial P}\right)_T \left(\frac{\partial P}{\partial T}\right)_s \left(\frac{\partial \nu}{\partial s}\right)_T \left(\frac{\partial T}{\partial \nu}\right)_s = \left(\frac{\partial s}{\partial P} \frac{\partial \nu}{\partial s}\right)_T \left(\frac{\partial P}{\partial T} \frac{\partial T}{\partial \nu}\right)_s = \left(\frac{\partial \nu}{\partial P}\right)_T \left(\frac{\partial P}{\partial \nu}\right)_s$$

but

$$\left(\frac{\partial \nu}{\partial P}\right)_T = \left(\frac{\partial (RT/P)}{\partial P}\right)_T = -\frac{\nu}{P}$$

Substituting,

$$\frac{c_p}{c_\nu} = -\frac{\nu}{P} \left(\frac{\partial P}{\partial \nu}\right)_s = k$$

which is the desired relation.

12-89 The c_p of nitrogen at 300 kPa and 400 K is to be estimated using the relation given and its definition, and the results are to be compared to the value listed in Table A-2b.

Analysis (a) We treat nitrogen as an ideal gas with $R = 0.297$ kJ/kg·K and $k = 1.397$. Note that $PT^{-k/(k-1)} = C = \text{constant}$ for the isentropic processes of ideal gases. The c_p relation is given as

$$c_p = T \left(\frac{\partial P}{\partial T} \right)_s \left(\frac{\partial v}{\partial T} \right)_p$$

$$v = \frac{RT}{P} \longrightarrow \left(\frac{\partial v}{\partial T} \right)_p = \frac{R}{P}$$

$$P = CT^{k/(k-1)} \longrightarrow \left(\frac{\partial P}{\partial T} \right)_s = \frac{k}{k-1} CT^{k/(k-1)-1} = \frac{k}{k-1} (PT^{-k/(k-1)}) T^{k/(k-1)-1} = \frac{kP}{T(k-1)}$$

Substituting,

$$c_p = T \left(\frac{kP}{T(k-1)} \right) \left(\frac{R}{P} \right) = \frac{kR}{k-1} = \frac{1.397(0.297 \text{ kJ/kg} \cdot \text{K})}{1.397-1} = 1.045 \text{ kJ/kg} \cdot \text{K}$$

(b) The c_p is defined as $c_p = \left(\frac{\partial h}{\partial T} \right)_p$. Replacing the differentials by differences,

$$c_p \cong \left(\frac{\Delta h}{\Delta T} \right)_{P=300\text{kPa}} = \frac{h(410 \text{ K}) - h(390 \text{ K})}{(410 - 390)\text{K}} = \frac{(11,932 - 11,347)/28.0 \text{ kJ/kg}}{(410 - 390)\text{K}} = \mathbf{1.045 \text{ kJ/kg} \cdot \text{K}}$$

(Compare: Table A-2b at 400 K $\rightarrow c_p = 1.044$ kJ/kg·K)

12-90 The temperature change of steam and the average Joule-Thomson coefficient during a throttling process are to be estimated.

Analysis The enthalpy of steam at 2.5 MPa and $T = 400^\circ\text{C}$ is $h = 3240.1$ kJ/kg. Now consider a throttling process from this state to 1.2 MPa. The temperature of the steam at the end of this throttling process will be

$$\left. \begin{array}{l} P = 1.2 \text{ MPa} \\ h = 3240.1 \text{ kJ/kg} \end{array} \right\} T_2 = 390.10^\circ\text{C}$$

Thus the temperature drop during this throttling process is

$$\Delta T = T_2 - T_1 = 390.10 - 400 = \mathbf{-9.90^\circ\text{C}}$$

The average Joule-Thomson coefficient for this process is determined from

$$\mu = \left(\frac{\partial T}{\partial P} \right)_h \cong \left(\frac{\Delta T}{\Delta P} \right)_{h=3240.1\text{kJ/kg}} = \frac{(390.10 - 400)^\circ\text{C}}{(1.2 - 2.5)\text{MPa}} = \mathbf{7.61^\circ\text{C/MPa}}$$

12-91 The volume expansivity of copper is given at two temperatures. The percent change in the volume of copper when it is heated at atmospheric pressure is to be determined.

Properties The volume expansivity of copper is given to be $49.2 \times 10^{-6} \text{ K}^{-1}$ at 300 K, and be $54.2 \times 10^{-6} \text{ K}^{-1}$ at 500 K

Analysis We take $\nu = \nu(P, T)$. Its total differential is

$$d\nu = \left(\frac{\partial \nu}{\partial T} \right)_P dT + \left(\frac{\partial \nu}{\partial P} \right)_T dP$$

which, for a constant pressure process, reduces to

$$d\nu = \left(\frac{\partial \nu}{\partial T} \right)_P dT$$

Dividing by ν and using the definition of β ,

$$\frac{d\nu}{\nu} = \frac{1}{\nu} \left(\frac{\partial \nu}{\partial T} \right)_P dT = \beta dT$$

Taking β to be a constant, integration from 1 to 2 yields

$$\ln \frac{\nu_2}{\nu_1} = \beta(T_2 - T_1)$$

or

$$\frac{\nu_2}{\nu_1} = \exp[\beta(T_2 - T_1)]$$

The average value of β is

$$\beta_{\text{ave}} = (\beta_1 + \beta_2)/2 = (49.2 \times 10^{-6} + 54.2 \times 10^{-6})/2 = 51.7 \times 10^{-6} \text{ K}^{-1}$$

Substituting the given values,

$$\frac{\nu_2}{\nu_1} = \exp[\beta(T_2 - T_1)] = \exp[(51.7 \times 10^{-6} \text{ K}^{-1})(500 - 300)\text{K}] = 1.0104$$

Therefore, the volume of copper block will increase by **1.04 percent**.

12-92 An adiabatic storage tank that is initially evacuated is connected to a supply line that carries nitrogen. A valve is opened, and nitrogen flows into the tank. The final temperature in the tank is to be determined by treating nitrogen as an ideal gas and using the generalized charts, and the results are to be compared to the given actual value.

Assumptions 1 Uniform flow conditions exist. 2 Kinetic and potential energies are negligible.

Analysis We take the tank as the system, which is a control volume since mass crosses the boundary. Noting that the microscopic energies of flowing and nonflowing fluids are represented by enthalpy h and internal energy u , respectively, the mass and energy balances for this uniform-flow system can be expressed as

$$\text{Mass balance: } m_{\text{in}} - m_{\text{out}} = \Delta m_{\text{system}} \rightarrow m_i = m_2 \quad (\text{since } m_{\text{out}} = m_{\text{initial}} = 0)$$

$$\text{Energy balance: } E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}} \rightarrow 0 + m_i h_i = m_2 u_2$$

$$\text{Combining the two balances: } u_2 = h_i$$

(a) From the ideal gas property table of nitrogen, at 225 K we read

$$\bar{u}_2 = \bar{h}_i = \bar{h}_{@225 \text{ K}} = 6,537 \text{ kJ/kmol}$$

The temperature that corresponds to this \bar{u}_2 value is

$$T_2 = \mathbf{314.8 \text{ K}} \quad (7.4\% \text{ error})$$

(b) Using the generalized enthalpy departure chart, h_i is determined to be

$$\left. \begin{aligned} T_{R,i} &= \frac{T_i}{T_{\text{cr}}} = \frac{225}{126.2} = 1.78 \\ P_{R,i} &= \frac{P_i}{P_{\text{cr}}} = \frac{10}{3.39} = 2.95 \end{aligned} \right\} Z_{h,i} = \frac{\bar{h}_{i,\text{ideal}} - \bar{h}_i}{R_u T_{\text{cr}}} = 0.9 \quad (\text{Fig. A-29})$$

Thus,

$$\bar{h}_i = \bar{h}_{i,\text{ideal}} - 0.9 R_u T_{\text{cr}} = 6,537 - (0.9)(8.314)(126.2) = 5,593 \text{ kJ/kmol}$$

and

$$\bar{u}_2 = \bar{h}_i = 5,593 \text{ kJ/kmol}$$

Try $T_2 = 280 \text{ K}$. Then at $P_{R2} = 2.95$ and $T_{R2} = 2.22$ we read $Z_2 = 0.98$ and $(\bar{h}_{2,\text{ideal}} - \bar{h}_2) / R_u T_{\text{cr}} = 0.55$

Thus,

$$\bar{h}_2 = \bar{h}_{2,\text{ideal}} - 0.55 R_u T_{\text{cr}} = 8,141 - (0.55)(8.314)(126.2) = 7,564 \text{ kJ/kmol}$$

$$\bar{u}_2 = \bar{h}_2 - Z R_u T_2 = 7,564 - (0.98)(8.314)(280) = 5,283 \text{ kJ/kmol}$$

Try $T_2 = 300 \text{ K}$. Then at $P_{R2} = 2.95$ and $T_{R2} = 2.38$ we read $Z_2 = 1.0$ and $(\bar{h}_{2,\text{ideal}} - \bar{h}_2) / R_u T_{\text{cr}} = 0.50$

Thus,

$$\bar{h}_2 = \bar{h}_{2,\text{ideal}} - 0.50 R_u T_{\text{cr}} = 8,723 - (0.50)(8.314)(126.2) = 8,198 \text{ kJ/kmol}$$

$$\bar{u}_2 = \bar{h}_2 - Z R_u T_2 = 8,198 - (1.0)(8.314)(300) = 5,704 \text{ kJ/kmol}$$

By linear interpolation,

$$T_2 = \mathbf{294.7 \text{ K}} \quad (0.6\% \text{ error})$$

12-93E Argon gas enters a turbine at a specified state and leaves at another specified state. The power output of the turbine and the exergy destruction associated with the process are to be determined using the generalized charts.

Properties The gas constant and critical properties of argon are $R = 0.04971 \text{ Btu/lbm}\cdot\text{R}$, $T_{cr} = 272 \text{ R}$, and $P_{cr} = 705 \text{ psia}$ (Table A-1E).

Analysis (a) The enthalpy and entropy departures of argon at the specified states are determined from the generalized charts to be

$$\left. \begin{aligned} T_{R_1} &= \frac{T_1}{T_{cr}} = \frac{1000}{272} = 3.68 \\ P_{R_1} &= \frac{P_1}{P_{cr}} = \frac{1000}{705} = 1.418 \end{aligned} \right\} Z_{h_1} \cong 0 \text{ and } Z_{s_1} \cong 0$$

Thus argon behaves as an ideal gas at turbine inlet. Also,

$$\left. \begin{aligned} T_{R_2} &= \frac{T_2}{T_{cr}} = \frac{500}{272} = 1.838 \\ P_{R_2} &= \frac{P_2}{P_{cr}} = \frac{150}{705} = 0.213 \end{aligned} \right\} Z_{h_2} = 0.04 \text{ and } Z_{s_2} = 0.02$$

Thus,

$$\begin{aligned} h_2 - h_1 &= RT_{cr} (Z_{h_1} - Z_{h_2}) + (h_2 - h_1)_{ideal} \\ &= (0.04971)(272)(0 - 0.04) + 0.1253(500 - 1000) = -63.2 \text{ Btu/lbm} \end{aligned}$$

The power output of the turbine is to be determined from the energy balance equation,

$$\begin{aligned} \dot{E}_{in} - \dot{E}_{out} &= \Delta \dot{E}_{system} = 0 \text{ (steady)} \rightarrow \dot{E}_{in} = \dot{E}_{out} \\ \dot{m}(h_1 + V_1^2/2) &= \dot{m}(h_2 + V_2^2/2) + \dot{Q}_{out} + \dot{W}_{out} \rightarrow \dot{W}_{out} = -\dot{m} \left[(h_2 - h_1) + \frac{V_2^2 - V_1^2}{2} \right] - \dot{Q}_{out} \\ \dot{W}_{out} &= -(12 \text{ lbm/s}) \left(-63.2 + \frac{(450 \text{ ft/s})^2 - (300 \text{ ft/s})^2}{2} \left(\frac{1 \text{ Btu/lbm}}{25,037 \text{ ft}^2/\text{s}^2} \right) \right) - 80 \text{ Btu/s} \\ &= \mathbf{651.4 \text{ Btu/s} = 922 \text{ hp}} \end{aligned}$$

(b) Under steady conditions, the rate form of the entropy balance for the turbine simplifies to

$$\begin{aligned} \dot{S}_{in} - \dot{S}_{out} + \dot{S}_{gen} &= \Delta \dot{S}_{system} \stackrel{\approx 0}{=} 0 \\ \dot{m}s_1 - \dot{m}s_2 - \frac{\dot{Q}_{out}}{T_{b,out}} + \dot{S}_{gen} &= 0 \rightarrow \dot{S}_{gen} = \dot{m}(s_2 - s_1) + \frac{\dot{Q}_{out}}{T_0} \end{aligned}$$

The exergy destroyed during a process can be determined from an exergy balance or directly from its definition $\dot{X}_{destroyed} = T_0 \dot{S}_{gen}$,

$$\dot{X}_{destroyed} = T_0 \dot{S}_{gen} = T_0 \left(\dot{m}(s_2 - s_1) + \frac{\dot{Q}_{out}}{T_0} \right)$$

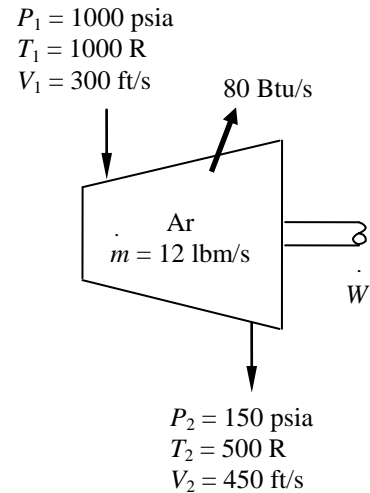

where $s_2 - s_1 = R(Z_{s_1} - Z_{s_2}) + (s_2 - s_1)_{ideal}$

and $(s_2 - s_1)_{ideal} = c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} = 0.1253 \ln \frac{500}{1000} - 0.04971 \ln \frac{150}{1000} = 0.00745 \text{ Btu/lbm}\cdot\text{R}$

Thus $s_2 - s_1 = R(Z_{s_1} - Z_{s_2}) + (s_2 - s_1)_{ideal} = (0.04971)[0 - (0.02)] + 0.00745 = 0.00646 \text{ Btu/lbm}\cdot\text{R}$

Substituting,

$$\dot{X}_{destroyed} = (535 \text{ R}) \left((12 \text{ lbm/s})(0.00646 \text{ Btu/lbm}\cdot\text{R}) + \frac{80 \text{ Btu/s}}{535 \text{ R}} \right) = 121.5 \text{ Btu/s} \cong \mathbf{122 \text{ Btu/s}}$$

12-94E Methane is to be adiabatically and reversibly compressed in a steady-flow device. The specific work required for this compression is to be determined using the departure charts and treating the methane as an ideal gas with temperature variable specific heats.

Properties The properties of methane are (Table A-1E)

$$M = 16.043 \text{ lbm/lbmol}, R = 0.1238 \text{ Btu/lbm} \cdot \text{R}, T_{\text{cr}} = 343.9 \text{ R}, P_{\text{cr}} = 673 \text{ psia}$$

Analysis The temperature at the exit state may be determined by the fact that the process is isentropic and the molar entropy change between the inlet and exit is zero. When the expression of Table A-2E is substituted for c_p and the integration performed, we obtain

$$\begin{aligned} (\bar{s}_2 - \bar{s}_1)_{\text{ideal}} &= \int_1^2 \frac{c_p}{T} dT - R_u \ln \frac{P_2}{P_1} = \int_1^2 \left(\frac{a}{T} + b + cT + dT^2 \right) dT - R_u \ln \frac{P_2}{P_1} \\ &= a \ln \frac{T_2}{T_1} + b(T_2 - T_1) + \frac{c}{2}(T_2^2 - T_1^2) + \frac{d}{3}(T_2^3 - T_1^3) - R_u \ln \frac{P_2}{P_1} \end{aligned}$$

Substituting,

$$\begin{aligned} 0 &= 4.75 \ln \frac{T_2}{560} + 0.006666(T_2 - 560) + \frac{0.09352 \times 10^{-5}}{2}(T_2^2 - 560^2) \\ &\quad - \frac{0.4510 \times 10^{-9}}{3}(T_2^3 - 560^3) - (1.9858) \ln \frac{500}{50} \end{aligned}$$

Solving this equation by EES or an iterative solution gives

$$T_2 = 892 \text{ R}$$

When an energy balance is applied to the compressor, it becomes

$$\begin{aligned} \bar{w}_{\text{in}} &= (\bar{h}_2 - \bar{h}_1)_{\text{ideal}} = \int_1^2 c_p dT = \int_1^2 (a + bT + cT^2 + dT^3) dT \\ &= a(T_2 - T_1) + \frac{b}{2}(T_2^2 - T_1^2) + \frac{c}{3}(T_2^3 - T_1^3) + \frac{d}{4}(T_2^4 - T_1^4) \\ &= 4.75(892 - 560) + \frac{0.006666}{2}(892^2 - 560^2) + \frac{0.09352 \times 10^{-5}}{3}(892^3 - 560^3) \\ &\quad - \frac{0.4510 \times 10^{-9}}{4}(892^4 - 560^4) \\ &= 3290 \text{ Btu/lbmol} \end{aligned}$$

The work input per unit mass basis is

$$w_{\text{in}} = \frac{\bar{w}_{\text{in}}}{M} = \frac{3290 \text{ Btu/lbmol}}{16.043 \text{ lbm/lbmol}} = \mathbf{205.1 \text{ Btu/lbm}}$$

The enthalpy departures of propane at the specified states are determined from the generalized charts to be (Fig. A-29 or from EES)

$$\left. \begin{aligned} T_{R1} &= \frac{T_1}{T_{\text{cr}}} = \frac{560}{343.9} = 1.628 \\ P_{R1} &= \frac{P_1}{P_{\text{cr}}} = \frac{50}{673} = 0.0743 \end{aligned} \right\} \longrightarrow Z_{h1} = 0.0332$$

and

$$\left. \begin{aligned} T_{R2} &= \frac{T_2}{T_{\text{cr}}} = \frac{892}{343.9} = 2.594 \\ P_{R2} &= \frac{P_2}{P_{\text{cr}}} = \frac{500}{673} = 0.743 \end{aligned} \right\} \longrightarrow Z_{h2} = 0.0990$$

The work input is determined to be

$$\begin{aligned} w_{\text{in}} &= h_2 - h_1 = (h_2 - h_1)_{\text{ideal}} - RT_{\text{cr}}(Z_{h2} - Z_{h1}) \\ &= 205.1 \text{ Btu/lbm} - (0.1238 \text{ Btu/lbm} \cdot \text{R})(343.9 \text{ R})(0.0990 - 0.0332) \\ &= \mathbf{202.3 \text{ Btu/lbm}} \end{aligned}$$

12-95  The work done by the refrigerant 134a as it undergoes an isothermal process in a closed system is to be determined using the tabular (EES) data and the generalized charts.

Analysis The solution using EES built-in property data is as follows:

$$\left. \begin{array}{l} T_1 = 40^\circ\text{C} \\ P_1 = 2 \text{ MPa} \end{array} \right\} \begin{array}{l} u_1 = 106.39 \text{ kJ/kg} \\ s_1 = 0.3917 \text{ kJ/kg}\cdot\text{K} \end{array}$$

$$\left. \begin{array}{l} T_2 = 40^\circ\text{C} \\ P_2 = 0.1 \text{ MPa} \end{array} \right\} \begin{array}{l} u_2 = 264.27 \text{ kJ/kg} \\ s_2 = 1.1485 \text{ kJ/kg}\cdot\text{K} \end{array}$$

$$\Delta s_{\text{EES}} = s_2 - s_1 = 1.1485 - 0.3917 = 0.7568 \text{ kJ/kg}\cdot\text{K}$$

$$q_{\text{EES}} = T_1 \Delta s_{\text{EES}} = (40 + 273.15 \text{ K})(0.7568 \text{ kJ/kg}\cdot\text{K}) = 237.00 \text{ kJ/kg}$$

$$w_{\text{EES}} = q_{\text{EES}} - (u_2 - u_1) = 237.00 - (264.27 - 106.39) = \mathbf{79.1 \text{ kJ/kg}}$$

For the generalized chart solution we first determine the following factors using EES as

$$\left. \begin{array}{l} T_{R1} = \frac{T_1}{T_{cr}} = \frac{313.2}{374.2} = 0.8369 \\ P_{R1} = \frac{P_1}{P_{cr}} = \frac{2}{4.059} = 0.4927 \end{array} \right\} \longrightarrow Z_1 = 0.08357, Z_{h1} = 4.82 \text{ and } Z_{s1} = 5.147$$

$$\left. \begin{array}{l} T_{R2} = \frac{T_2}{T_{cr}} = \frac{313.2}{374.2} = 0.8369 \\ P_{R2} = \frac{P_2}{P_{cr}} = \frac{0.1}{4.059} = 0.02464 \end{array} \right\} \longrightarrow Z_2 = 0.9857, Z_{h2} = 0.03396 \text{ and } Z_{s2} = 0.02635$$

Then,

$$\Delta h_1 = Z_{h1} R T_{cr} = (4.82)(0.08148 \text{ kJ/kg}\cdot\text{K})(374.2 \text{ K}) = 146.97 \text{ kJ/kg}$$

$$\Delta s_1 = Z_{s1} R = (5.147)(0.08148 \text{ kJ/kg}\cdot\text{K}) = 0.4194 \text{ kJ/kg}\cdot\text{K}$$

$$\Delta h_2 = Z_{h2} R T_{cr} = (0.03396)(0.08148 \text{ kJ/kg}\cdot\text{K})(374.2 \text{ K}) = 1.04 \text{ kJ/kg}$$

$$\Delta s_2 = Z_{s2} R = (0.02635)(0.08148 \text{ kJ/kg}\cdot\text{K}) = 0.002147 \text{ kJ/kg}\cdot\text{K}$$

$$\Delta s_{\text{ideal}} = R \ln \frac{P_2}{P_1} = (0.08148 \text{ kJ/kg}\cdot\text{K}) \ln \left(\frac{0.1}{2} \right) = 0.2441 \text{ kJ/kg}\cdot\text{K}$$

$$\Delta s_{\text{chart}} = \Delta s_{\text{ideal}} - (\Delta s_2 - \Delta s_1) = 0.2441 - (0.002147 - 0.4194) = 0.6613 \text{ kJ/kg}\cdot\text{K}$$

$$q_{\text{chart}} = T_1 \Delta s_{\text{chart}} = (40 + 273.15 \text{ K})(0.6613 \text{ kJ/kg}\cdot\text{K}) = 207.09 \text{ kJ/kg}$$

$$\begin{aligned} \Delta u_{\text{chart}} &= \Delta h_{\text{ideal}} - (\Delta h_2 - \Delta h_1) - (Z_2 R T_2 - Z_1 R T_1) \\ &= 0 - (1.04 - 146.97) - [(0.9857)(0.08148)(313.2) - (0.08357)(0.08148)(313.2)] \\ &= 122.92 \text{ kJ/kg} \end{aligned}$$

$$w_{\text{chart}} = q_{\text{chart}} - \Delta u_{\text{chart}} = 207.09 - 122.92 = \mathbf{84.2 \text{ kJ/kg}}$$

12-96 The initial state and the final temperature of argon contained in a rigid tank are given. The mass of the argon in the tank, the final pressure, and the heat transfer are to be determined using the generalized charts.

Analysis (a) The compressibility factor of argon at the initial state is determined from the generalized chart to be

$$\left. \begin{aligned} T_{R_1} &= \frac{T_1}{T_{cr}} = \frac{173}{151.0} = 1.146 \\ P_{R_1} &= \frac{P_1}{P_{cr}} = \frac{1}{4.86} = 0.206 \end{aligned} \right\} Z_1 = 0.95 \text{ and } Z_{h_1} = 0.18$$

Then,

$$Pv = ZRT \longrightarrow v = \frac{ZRT}{P} = \frac{(0.95)(0.2081 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(173 \text{ K})}{1000 \text{ kPa}} = 0.0342 \text{ m}^3/\text{kg}$$

$$m = \frac{V}{v} = \frac{1.2 \text{ m}^3}{0.0342 \text{ m}^3/\text{kg}} = \mathbf{35.1 \text{ kg}}$$

(b) The specific volume of argon remains constant during this process, $v_2 = v_1$. Thus,

$$\left. \begin{aligned} T_{R_2} &= \frac{T_2}{T_{cr}} = \frac{273}{151.0} = 1.808 \\ v_{R_2} &= \frac{v_2}{RT_{cr}/P_{cr}} = \frac{0.0342 \text{ m}^3/\text{kg}}{(0.2081 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(151 \text{ K})(4860 \text{ kPa})} = 5.29 \end{aligned} \right\} \begin{aligned} P_{R_2} &= 0.315 \\ Z_2 &= 0.99 \\ Z_{h_2} &\cong 0 \end{aligned}$$

$$P_2 = P_{R_2} P_{cr} = (0.315)(4860) = 1531 \text{ kPa}$$

(c) The energy balance relation for this closed system can be expressed as

$$\begin{aligned} E_{in} - E_{out} &= \Delta E_{\text{system}} \\ Q_{in} &= \Delta U = m(u_2 - u_1) \\ Q_{in} &= m[h_2 - h_1 - (P_2 v_2 - P_1 v_1)] = m[h_2 - h_1 - R(Z_2 T_2 - Z_1 T_1)] \end{aligned}$$

where

$$h_2 - h_1 = RT_{cr}(Z_{h_1} - Z_{h_2}) + (h_2 - h_1)_{\text{ideal}} = (0.2081)(151)(0.18 - 0) + 0.5203(0 - (-100)) = 57.69 \text{ kJ/kg}$$

Thus,

$$Q_{in} = (35.1 \text{ kg})[57.69 - (0.2081 \text{ kJ/kg} \cdot \text{K})[(0.99)(273) - (0.95)(173)]] = \mathbf{1251 \text{ kJ}}$$

12-97 The heat transfer, work, and entropy changes of methane during a process in a piston-cylinder device are to be determined assuming ideal gas behavior, using generalized charts, and real fluid (EES) data.

Analysis The ideal gas solution: (Properties are obtained from EES)

State 1:

$$\begin{aligned} T_1 &= 100^\circ\text{C} \longrightarrow h_1 = -4473.3 \text{ kJ/kg} \\ T_1 &= 100^\circ\text{C}, P_1 = 5 \text{ MPa} \longrightarrow s_1 = 10.116 \text{ kJ/kg}\cdot\text{K} \\ u_1 &= h_1 - RT_1 = (-4473.3) - (0.5182)(100 + 273.15) = -4666.7 \text{ kJ/kg} \\ \nu_1 &= R \frac{T_1}{P_1} = (0.5182 \text{ kJ/kg}\cdot\text{K}) \left(\frac{100 + 273.15 \text{ K}}{5000 \text{ kPa}} \right) = 0.03868 \text{ m}^3/\text{kg} \end{aligned}$$

State 2:

$$\begin{aligned} T_2 &= 250^\circ\text{C} \longrightarrow h_2 = -4063.0 \text{ kJ/kg} \\ T_2 &= 250^\circ\text{C}, P_2 = 5 \text{ MPa} \longrightarrow s_2 = 11.035 \text{ kJ/kg}\cdot\text{K} \\ u_2 &= h_2 - RT_2 = (-4063.0) - (0.5182)(250 + 273.15) = -4334.1 \text{ kJ/kg} \\ \nu_2 &= R \frac{T_2}{P_2} = (0.5182 \text{ kJ/kg}\cdot\text{K}) \left(\frac{250 + 273.15 \text{ K}}{5000 \text{ kPa}} \right) = 0.05422 \text{ m}^3/\text{kg} \\ w_{\text{ideal}} &= P(\nu_2 - \nu_1) = (5000 \text{ kPa})(0.05422 - 0.03868) \text{ m}^3/\text{kg} = \mathbf{77.73 \text{ kJ/kg}} \\ q_{\text{ideal}} &= w_{\text{ideal}} + (u_2 - u_1) = 77.73 + [(-4334.1) - (-4666.7)] = \mathbf{410.3 \text{ kJ/kg}} \\ \Delta s_{\text{ideal}} &= s_2 - s_1 = 11.035 - 10.116 = \mathbf{0.919 \text{ kJ/kg}} \end{aligned}$$

For the generalized chart solution we first determine the following factors using EES as

$$\left. \begin{aligned} T_{R1} &= \frac{T_1}{T_{\text{cr}}} = \frac{373.2}{304.2} = 1.227 \\ P_{R1} &= \frac{P_1}{P_{\text{cr}}} = \frac{5}{7.39} = 0.6766 \end{aligned} \right\} \longrightarrow Z_1 = 0.8773, Z_{h1} = 0.5493 \text{ and } Z_{s1} = 0.3269$$

$$\left. \begin{aligned} T_{R2} &= \frac{T_2}{T_{\text{cr}}} = \frac{523.2}{304.2} = 1.720 \\ P_{R2} &= \frac{P_2}{P_{\text{cr}}} = \frac{5}{7.39} = 0.6766 \end{aligned} \right\} \longrightarrow Z_2 = 0.9739, Z_{h2} = 0.2676 \text{ and } Z_{s2} = 0.1281$$

State 1:

$$\begin{aligned} \Delta h_1 &= Z_{h1} RT_{\text{cr}} = (0.5493)(0.5182 \text{ kJ/kg}\cdot\text{K})(304.2 \text{ K}) = 86.60 \text{ kJ/kg} \\ h_1 &= h_{1,\text{ideal}} - \Delta h_1 = (-4473.3) - 86.60 = -4559.9 \text{ kJ/kg} \\ u_1 &= h_1 - Z_1 RT_1 = (-4559.9) - (0.8773)(0.5182)(373.15) = -4729.6 \text{ kJ/kg} \\ \nu_1 &= Z_1 R \frac{T_1}{P_1} = (0.8773)(0.5182) \frac{373.15}{5000} = 0.03393 \text{ m}^3/\text{kg} \\ \Delta s_1 &= Z_{s1} R = (0.3269)(0.5182 \text{ kJ/kg}\cdot\text{K}) = 0.1694 \text{ kJ/kg}\cdot\text{K} \\ s_1 &= s_{1,\text{ideal}} - \Delta s_1 = 10.116 - 0.1694 = 9.946 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

State 2:

$$\begin{aligned} \Delta h_2 &= Z_{h2} RT_{\text{cr}} = (0.2676)(0.5182 \text{ kJ/kg}\cdot\text{K})(304.2 \text{ K}) = 42.19 \text{ kJ/kg} \\ h_2 &= h_{2,\text{ideal}} - \Delta h_2 = (-4063.0) - 42.19 = -4105.2 \text{ kJ/kg} \\ u_2 &= h_2 - Z_2 RT_2 = (-4105.2) - (0.9739)(0.5182)(523.15) = -4369.2 \text{ kJ/kg} \end{aligned}$$

$$v_2 = Z_2 R \frac{T_2}{P_2} = (0.9739)(0.5182) \frac{523.15}{5000} = 0.05281 \text{ m}^3/\text{kg}$$

$$\Delta s_2 = Z_{s2} R = (0.1281)(0.5182 \text{ kJ/kg}\cdot\text{K}) = 0.06639 \text{ kJ/kg}\cdot\text{K}$$

$$s_2 = s_{2,\text{ideal}} - \Delta s_2 = 11.035 - 0.06639 = 10.968 \text{ kJ/kg}\cdot\text{K}$$

Then,

$$w_{\text{chart}} = P(v_2 - v_1) = (5000 \text{ kPa})(0.05281 - 0.03393) \text{ m}^3/\text{kg} = \mathbf{94.38 \text{ kJ/kg}}$$

$$q_{\text{chart}} = w_{\text{chart}} + (u_2 - u_1) = 94.38 + [(-4369.2) - (-4729.6)] = \mathbf{454.7 \text{ kJ/kg}}$$

$$\Delta s_{\text{chart}} = s_2 - s_1 = 10.968 - 9.946 = \mathbf{1.02 \text{ kJ/kg}}$$

The solution using EES built-in property data is as follows:

$$\left. \begin{array}{l} T_1 = 100^\circ\text{C} \\ P_1 = 5 \text{ MPa} \end{array} \right\} \begin{array}{l} v_1 = 0.03753 \text{ m}^3/\text{kg} \\ u_1 = -45.10 \text{ kJ/kg} \\ s_1 = -1.569 \text{ kJ/kg}\cdot\text{K} \end{array}$$

$$\left. \begin{array}{l} T_2 = 250^\circ\text{C} \\ P_2 = 5 \text{ MPa} \end{array} \right\} \begin{array}{l} v_2 = 0.05443 \text{ m}^3/\text{kg} \\ u_2 = 293.22 \text{ kJ/kg} \\ s_2 = -0.6204 \text{ kJ/kg}\cdot\text{K} \end{array}$$

$$w_{\text{EES}} = P(v_2 - v_1) = (5000 \text{ kPa})(0.05443 - 0.03753) \text{ m}^3/\text{kg} = \mathbf{84.47 \text{ kJ/kg}}$$

$$q_{\text{EES}} = w_{\text{EES}} + (u_2 - u_1) = 84.47 + [293.22 - (-45.10)] = \mathbf{422.8 \text{ kJ/kg}}$$

$$\Delta s_{\text{EES}} = s_2 - s_1 = -0.6204 - (-1.569) = \mathbf{0.948 \text{ kJ/kg}}$$

12-98E Methane is compressed steadily. The entropy change and the specific work required are to be determined using the departure charts and the property tables.

Properties The properties of methane are (Table A-1E)

$$M = 16.043 \text{ lbm/lbmol}, T_{\text{cr}} = 343.9 \text{ R}, P_{\text{cr}} = 673 \text{ psia}, c_p = 0.532 \text{ Btu/lbm} \cdot \text{R}, R = 0.1238 \text{ Btu/lbm} \cdot \text{R}$$

Analysis (a) Using empirical correlation for the c_p of methane as given in Table A-2Ec gives

$$\begin{aligned} \bar{h}_2 - \bar{h}_1 &= \int c_p dT = \int (a + bT + cT^2 + dT^3) dT \\ &= a(T_2 - T_1) + \frac{b}{2}(T_2^2 - T_1^2) + \frac{c}{3}(T_2^3 - T_1^3) + \frac{d}{4}(T_2^4 - T_1^4) \\ &= 4.750(1000) + \frac{0.6666 \times 10^{-2}}{2}(1560^2 - 560^2) + \frac{0.09352 \times 10^{-5}}{3}(1560^3 - 560^3) \\ &\quad + \frac{-0.4510 \times 10^{-9}}{4}(1560^4 - 560^4) \\ &= 12,288 \text{ Btu/lbmol} \cdot \text{R} \end{aligned}$$

The work input is equal to the enthalpy change. The enthalpy change per unit mass is

$$w_{\text{in}} = h_2 - h_1 = \frac{\bar{h}_2 - \bar{h}_1}{M} = \frac{12,288 \text{ Btu/lbmol}}{16.043 \text{ lbm/lbmol}} = \mathbf{765.9 \text{ Btu/lbm}}$$

Similarly, the entropy change is given by

$$\begin{aligned} (\bar{s}_2 - \bar{s}_1)_{\text{ideal}} &= \int_1^2 \frac{c_p}{T} dT - R_u \ln \frac{P_2}{P_1} = \int_1^2 \left(\frac{a}{T} + b + cT + dT^2 \right) dT - R_u \ln \frac{P_2}{P_1} \\ &= a \ln \frac{T_2}{T_1} + b(T_2 - T_1) + \frac{c}{2}(T_2^2 - T_1^2) + \frac{d}{3}(T_2^3 - T_1^3) - R_u \ln \frac{P_2}{P_1} \\ &= 4.750 \ln \frac{1560}{560} + 0.6666 \times 10^{-2} (1560 - 560) + \frac{0.09352 \times 10^{-5}}{2} (1560^2 - 560^2) \\ &\quad + \frac{-0.4510 \times 10^{-9}}{3} (1560^3 - 560^3) - (1.9858) \ln \frac{500}{50} \\ &= 7.407 \text{ Btu/lbmol} \cdot \text{R} \end{aligned}$$

The entropy change per unit mass is

$$(s_2 - s_1)_{\text{ideal}} = \frac{(\bar{s}_2 - \bar{s}_1)_{\text{ideal}}}{M} = \frac{7.407 \text{ Btu/lbmol} \cdot \text{R}}{16.043 \text{ lbm/lbmol}} = \mathbf{0.4617 \text{ Btu/lbm} \cdot \text{R}}$$

(b) The enthalpy and entropy departures of water vapor at the specified states are determined from the generalized charts to be (Figs. A-29, A-30 or from EES. We used EES.)

$$\left. \begin{aligned} T_{R1} &= \frac{T_1}{T_{\text{cr}}} = \frac{560}{343.9} = 1.63 \\ P_{R1} &= \frac{P_1}{P_{\text{cr}}} = \frac{50}{673} = 0.0743 \end{aligned} \right\} \longrightarrow Z_{h1} = 0.03313 \text{ and } Z_{s1} = 0.01617$$

and

$$\left. \begin{aligned} T_{R2} &= \frac{T_2}{T_{\text{cr}}} = \frac{1560}{343.9} = 4.54 \\ P_{R2} &= \frac{P_2}{P_{\text{cr}}} = \frac{500}{673} = 0.743 \end{aligned} \right\} \longrightarrow Z_{h2} = 0 \text{ and } Z_{s2} = 0.00695$$

The work input and entropy changes are

$$\begin{aligned} w_{\text{in}} = h_2 - h_1 &= (h_2 - h_1)_{\text{ideal}} - RT_{\text{cr}}(Z_{h2} - Z_{h1}) \\ &= 765.9 - (0.1238)(343.9)(0 - 0.03313) = \mathbf{767.4 \text{ Btu/lbm}} \end{aligned}$$

$$\begin{aligned} s_2 - s_1 &= (s_2 - s_1)_{\text{ideal}} - R(Z_{s2} - Z_{s1}) \\ &= 0.4617 - (0.1238)(0.00695 - 0.01617) = \mathbf{0.4628 \text{ Btu/lbm} \cdot \text{R}} \end{aligned}$$

12-99E Methane is compressed in a steady-flow device. The second-law efficiency of the compression process is to be determined.

Analysis The reversible work input to the compressor is determined from

$$w_{\text{rev}} = h_2 - h_1 - T_0(s_2 - s_1) = 767.4 \text{ Btu/lbm} - (537 \text{ R})(0.4628 \text{ Btu/lbm} \cdot \text{R}) = 518.8 \text{ Btu/lbm}$$

The second-law efficiency of the compressor is

$$\eta_{\text{II}} = \frac{w_{\text{rev}}}{w_{\text{actual}}} = \frac{518.8}{767.4} = 0.676 = \mathbf{67.6\%}$$

Fundamentals of Engineering (FE) Exam Problems

12-100 A substance whose Joule-Thomson coefficient is negative is throttled to a lower pressure. During this process, (select the correct statement)

- (a) the temperature of the substance will increase.
- (b) the temperature of the substance will decrease.
- (c) the entropy of the substance will remain constant.
- (d) the entropy of the substance will decrease.
- (e) the enthalpy of the substance will decrease.

Answer (a) the temperature of the substance will increase.

12-101 Consider the liquid-vapor saturation curve of a pure substance on the P - T diagram. The magnitude of the slope of the tangent line to this curve at a temperature T (in Kelvin) is

- (a) proportional to the enthalpy of vaporization h_{fg} at that temperature,
- (b) proportional to the temperature T ,
- (c) proportional to the square of the temperature T ,
- (d) proportional to the volume change v_{fg} at that temperature,
- (e) inversely proportional to the entropy change s_{fg} at that temperature,

Answer (a) proportional to the enthalpy of vaporization h_{fg} at that temperature,

12-102 Based on the generalized charts, the error involved in the enthalpy of CO₂ at 300 K and 5 MPa if it is assumed to be an ideal gas is

- (a) 0 (b) 9% (c) 16% (d) 22% (e) 27%

Answer (e) 27%

12-104 For a gas whose equation of state is $P(\nu - b) = RT$, the specific heat difference $c_p - c_\nu$ is equal to

- (a) R (b) $R - b$ (c) $R + b$ (d) 0 (e) $R(1 + \nu/b)$

Answer (a) R

Solution The general relation for the specific heat difference $c_p - c_\nu$ is

$$c_p - c_\nu = -T \left(\frac{\partial \nu}{\partial T} \right)_P^2 \left(\frac{\partial P}{\partial \nu} \right)_T$$

For the given gas, $P(\nu - b) = RT$. Then,

$$\nu = \frac{RT}{P} + b \longrightarrow \left(\frac{\partial \nu}{\partial T} \right)_P = \frac{R}{P}$$

$$P = \frac{RT}{\nu - b} \longrightarrow \left(\frac{\partial P}{\partial \nu} \right)_T = -\frac{RT}{(\nu - b)^2} = -\frac{P}{\nu - b}$$

Substituting,

$$c_p - c_\nu = -T \left(\frac{R}{P} \right)^2 \left(-\frac{P}{\nu - b} \right) = \frac{TR^2}{P(\nu - b)} = R$$

Composition of Gas Mixtures

13-1C The mass fractions will be identical, but the mole fractions will not.

13-2C Yes.

13-3C Yes, because both CO_2 and N_2O has the same molar mass, $M = 44 \text{ kg/kmol}$.

13-4C No. We can do this only when each gas has the same mole fraction.

13-5C It is the average or the equivalent molar mass of the gas mixture. No.

13-6 From the definition of mass fraction,

$$\text{mf}_i = \frac{m_i}{m_m} = \frac{N_i M_i}{N_m M_m} = y_i \left(\frac{M_i}{M_m} \right)$$

13-7 A mixture consists of two gases. Relations for mole fractions when mass fractions are known are to be obtained .

Analysis The mass fractions of A and B are expressed as

$$\text{mf}_A = \frac{m_A}{m_m} = \frac{N_A M_A}{N_m M_m} = y_A \frac{M_A}{M_m} \quad \text{and} \quad \text{mf}_B = y_B \frac{M_B}{M_m}$$

Where m is mass, M is the molar mass, N is the number of moles, and y is the mole fraction. The apparent molar mass of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{N_A M_A + N_B M_B}{N_m} = y_A M_A + y_B M_B$$

Combining the two equation above and noting that $y_A + y_B = 1$ gives the following convenient relations for converting mass fractions to mole fractions,

$$y_A = \frac{M_B}{M_A (1/\text{mf}_A - 1) + M_B} \quad \text{and} \quad y_B = 1 - y_A$$

which are the desired relations.

13-8 The molar fractions of the constituents of moist air are given. The mass fractions of the constituents are to be determined.

Assumptions The small amounts of gases in air are ignored, and dry air is assumed to consist of N_2 and O_2 only.

Properties The molar masses of N_2 , O_2 , and H_2O are 28.0, 32.0, and 18.0 kg/kmol, respectively (Table A-1).

Analysis The molar mass of moist air is

$$M = \sum y_i M_i = 0.78 \times 28.0 + 0.20 \times 32.0 + 0.02 \times 18 = 28.6 \text{ kg/kmol}$$

Then the mass fractions of constituent gases are determined to be

$$N_2: \quad mf_{N_2} = y_{N_2} \frac{M_{N_2}}{M} = (0.78) \frac{28.0}{28.6} = \mathbf{0.764}$$

$$O_2: \quad mf_{O_2} = y_{O_2} \frac{M_{O_2}}{M} = (0.20) \frac{32.0}{28.6} = \mathbf{0.224}$$

$$H_2O: \quad mf_{H_2O} = y_{H_2O} \frac{M_{H_2O}}{M} = (0.02) \frac{18.0}{28.6} = \mathbf{0.013}$$

Therefore, the mass fractions of N_2 , O_2 , and H_2O in the air are 76.4%, 22.4%, and 1.3%, respectively.

Moist air
78% N_2
20% O_2
2% H_2O
(Mole fractions)

13-9 The molar fractions of the constituents of a gas mixture are given. The gravimetric analysis of the mixture, its molar mass, and gas constant are to be determined.

Properties The molar masses of N_2 , and CO_2 are 28.0 and 44.0 kg/kmol, respectively (Table A-1)

Analysis Consider 100 kmol of mixture. Then the mass of each component and the total mass are

$$N_{N_2} = 60 \text{ kmol} \longrightarrow m_{N_2} = N_{N_2} M_{N_2} = (60 \text{ kmol})(28 \text{ kg/kmol}) = 1680 \text{ kg}$$

$$N_{CO_2} = 40 \text{ kmol} \longrightarrow m_{CO_2} = N_{CO_2} M_{CO_2} = (40 \text{ kmol})(44 \text{ kg/kmol}) = 1760 \text{ kg}$$

$$m_m = m_{N_2} + m_{CO_2} = 1680 \text{ kg} + 1760 \text{ kg} = 3440 \text{ kg}$$

Then the mass fraction of each component (gravimetric analysis) becomes

$$mf_{N_2} = \frac{m_{N_2}}{m_m} = \frac{1680 \text{ kg}}{3440 \text{ kg}} = 0.488 \text{ or } \mathbf{48.8\%}$$

$$mf_{CO_2} = \frac{m_{CO_2}}{m_m} = \frac{1760 \text{ kg}}{3440 \text{ kg}} = 0.512 \text{ or } \mathbf{51.2\%}$$

mole
60% N_2
40% CO_2

The molar mass and the gas constant of the mixture are determined from their definitions,

$$M_m = \frac{m_m}{N_m} = \frac{3,440 \text{ kg}}{100 \text{ kmol}} = \mathbf{34.40 \text{ kg/kmol}}$$

and

$$R_m = \frac{R_u}{M_m} = \frac{8.314 \text{ kJ/kmol} \cdot \text{K}}{34.4 \text{ kg/kmol}} = \mathbf{0.242 \text{ kJ/kg} \cdot \text{K}}$$

13-10 The molar fractions of the constituents of a gas mixture are given. The gravimetric analysis of the mixture, its molar mass, and gas constant are to be determined.

Properties The molar masses of O₂ and CO₂ are 32.0 and 44.0 kg/kmol, respectively (Table A-1)

Analysis Consider 100 kmol of mixture. Then the mass of each component and the total mass are

$$N_{\text{O}_2} = 60 \text{ kmol} \longrightarrow m_{\text{O}_2} = N_{\text{O}_2} M_{\text{O}_2} = (60 \text{ kmol})(32 \text{ kg/kmol}) = 1920 \text{ kg}$$

$$N_{\text{CO}_2} = 40 \text{ kmol} \longrightarrow m_{\text{CO}_2} = N_{\text{CO}_2} M_{\text{CO}_2} = (40 \text{ kmol})(44 \text{ kg/kmol}) = 1760 \text{ kg}$$

$$m_m = m_{\text{O}_2} + m_{\text{CO}_2} = 1920 \text{ kg} + 1760 \text{ kg} = 3680 \text{ kg}$$

Then the mass fraction of each component (gravimetric analysis) becomes

$$\text{mf}_{\text{O}_2} = \frac{m_{\text{O}_2}}{m_m} = \frac{1920 \text{ kg}}{3680 \text{ kg}} = 0.522 \text{ or } \mathbf{52.2\%}$$

$$\text{mf}_{\text{CO}_2} = \frac{m_{\text{CO}_2}}{m_m} = \frac{1760 \text{ kg}}{3680 \text{ kg}} = 0.478 \text{ or } \mathbf{47.8\%}$$

mole
60% O ₂
40% CO ₂

The molar mass and the gas constant of the mixture are determined from their definitions,

$$M_m = \frac{m_m}{N_m} = \frac{3680 \text{ kg}}{100 \text{ kmol}} = \mathbf{36.80 \text{ kg/kmol}}$$

and

$$R_m = \frac{R_u}{M_m} = \frac{8.314 \text{ kJ/kmol} \cdot \text{K}}{36.8 \text{ kg/kmol}} = \mathbf{0.226 \text{ kJ/kg} \cdot \text{K}}$$

13-11 The masses of the constituents of a gas mixture are given. The mass fractions, the mole fractions, the average molar mass, and gas constant are to be determined.

Properties The molar masses of O₂, N₂, and CO₂ are 32.0, 28.0 and 44.0 kg/kmol, respectively (Table A-1)

Analysis (a) The total mass of the mixture is

$$m_m = m_{\text{O}_2} + m_{\text{N}_2} + m_{\text{CO}_2} = 2 \text{ kg} + 5 \text{ kg} + 7 \text{ kg} = 14 \text{ kg}$$

Then the mass fraction of each component becomes

$$\text{mf}_{\text{O}_2} = \frac{m_{\text{O}_2}}{m_m} = \frac{2 \text{ kg}}{14 \text{ kg}} = \mathbf{0.1429}$$

$$\text{mf}_{\text{N}_2} = \frac{m_{\text{N}_2}}{m_m} = \frac{5 \text{ kg}}{14 \text{ kg}} = \mathbf{0.3571}$$

$$\text{mf}_{\text{CO}_2} = \frac{m_{\text{CO}_2}}{m_m} = \frac{7 \text{ kg}}{14 \text{ kg}} = \mathbf{0.5}$$

<p>2 kg O₂ 5 kg N₂ 7 kg CO₂</p>
--

(b) To find the mole fractions, we need to determine the mole numbers of each component first,

$$N_{\text{O}_2} = \frac{m_{\text{O}_2}}{M_{\text{O}_2}} = \frac{2 \text{ kg}}{32 \text{ kg/kmol}} = 0.0625 \text{ kmol}$$

$$N_{\text{N}_2} = \frac{m_{\text{N}_2}}{M_{\text{N}_2}} = \frac{5 \text{ kg}}{28 \text{ kg/kmol}} = 0.1786 \text{ kmol}$$

$$N_{\text{CO}_2} = \frac{m_{\text{CO}_2}}{M_{\text{CO}_2}} = \frac{7 \text{ kg}}{44 \text{ kg/kmol}} = 0.1591 \text{ kmol}$$

Thus,

$$N_m = N_{\text{O}_2} + N_{\text{N}_2} + N_{\text{CO}_2} = 0.0625 \text{ kmol} + 0.1786 \text{ kmol} + 0.1591 \text{ kmol} = 0.4002 \text{ kmol}$$

and

$$y_{\text{O}_2} = \frac{N_{\text{O}_2}}{N_m} = \frac{0.0625 \text{ kmol}}{0.4002 \text{ kmol}} = \mathbf{0.1562}$$

$$y_{\text{N}_2} = \frac{N_{\text{N}_2}}{N_m} = \frac{0.1786 \text{ kmol}}{0.4002 \text{ kmol}} = \mathbf{0.4462}$$

$$y_{\text{CO}_2} = \frac{N_{\text{CO}_2}}{N_m} = \frac{0.1591 \text{ kmol}}{0.4002 \text{ kmol}} = \mathbf{0.3976}$$

(c) The average molar mass and gas constant of the mixture are determined from their definitions:

$$M_m = \frac{m_m}{N_m} = \frac{14 \text{ kg}}{0.4002 \text{ kmol}} = \mathbf{34.99 \text{ kg/kmol}}$$

and

$$R_m = \frac{R_u}{M_m} = \frac{8.314 \text{ kJ/kmol} \cdot \text{K}}{34.99 \text{ kg/kmol}} = \mathbf{0.2376 \text{ kJ/kg} \cdot \text{K}}$$

13-12 The mass fractions of the constituents of a gas mixture are given. The mole fractions of the gas and gas constant are to be determined.

Properties The molar masses of CH₄, and CO₂ are 16.0 and 44.0 kg/kmol, respectively (Table A-1)

Analysis For convenience, consider 100 kg of the mixture. Then the number of moles of each component and the total number of moles are

$$m_{\text{CH}_4} = 75 \text{ kg} \longrightarrow N_{\text{CH}_4} = \frac{m_{\text{CH}_4}}{M_{\text{CH}_4}} = \frac{75 \text{ kg}}{16 \text{ kg/kmol}} = 4.688 \text{ kmol}$$

$$m_{\text{CO}_2} = 25 \text{ kg} \longrightarrow N_{\text{CO}_2} = \frac{m_{\text{CO}_2}}{M_{\text{CO}_2}} = \frac{25 \text{ kg}}{44 \text{ kg/kmol}} = 0.568 \text{ kmol}$$

$$N_m = N_{\text{CH}_4} + N_{\text{CO}_2} = 4.688 \text{ kmol} + 0.568 \text{ kmol} = 5.256 \text{ kmol}$$

mass
75% CH ₄
25% CO ₂

Then the mole fraction of each component becomes

$$y_{\text{CH}_4} = \frac{N_{\text{CH}_4}}{N_m} = \frac{4.688 \text{ kmol}}{5.256 \text{ kmol}} = 0.892 \text{ or } \mathbf{89.2\%}$$

$$y_{\text{CO}_2} = \frac{N_{\text{CO}_2}}{N_m} = \frac{0.568 \text{ kmol}}{5.256 \text{ kmol}} = 0.108 \text{ or } \mathbf{10.8\%}$$

The molar mass and the gas constant of the mixture are determined from their definitions,

$$M_m = \frac{m_m}{N_m} = \frac{100 \text{ kg}}{5.256 \text{ kmol}} = 19.03 \text{ kg/kmol}$$

and

$$R_m = \frac{R_u}{M_m} = \frac{8.314 \text{ kJ/kmol} \cdot \text{K}}{19.03 \text{ kg/kmol}} = \mathbf{0.437 \text{ kJ/kg} \cdot \text{K}}$$

13-13 The mole numbers of the constituents of a gas mixture are given. The mass of each gas and the apparent gas constant are to be determined.

Properties The molar masses of H₂, and N₂ are 2.0 and 28.0 kg/kmol, respectively (Table A-1)

Analysis The mass of each component is determined from

$$N_{\text{H}_2} = 5 \text{ kmol} \longrightarrow m_{\text{H}_2} = N_{\text{H}_2} M_{\text{H}_2} = (5 \text{ kmol})(2.0 \text{ kg/kmol}) = \mathbf{10 \text{ kg}}$$

$$N_{\text{N}_2} = 2 \text{ kmol} \longrightarrow m_{\text{N}_2} = N_{\text{N}_2} M_{\text{N}_2} = (2 \text{ kmol})(28 \text{ kg/kmol}) = \mathbf{56 \text{ kg}}$$

The total mass and the total number of moles are

$$m_m = m_{\text{H}_2} + m_{\text{N}_2} = 10 \text{ kg} + 56 \text{ kg} = 66 \text{ kg}$$

$$N_m = N_{\text{H}_2} + N_{\text{N}_2} = 5 \text{ kmol} + 2 \text{ kmol} = 7 \text{ kmol}$$

6 kmol H ₂
2 kmol N ₂

The molar mass and the gas constant of the mixture are determined from their definitions,

$$M_m = \frac{m_m}{N_m} = \frac{66 \text{ kg}}{7 \text{ kmol}} = 9.43 \text{ kg/kmol}$$

and

$$R_m = \frac{R_u}{M_m} = \frac{8.314 \text{ kJ/kmol} \cdot \text{K}}{9.43 \text{ kg/kmol}} = \mathbf{0.881 \text{ kJ/kg} \cdot \text{K}}$$

P-v-T Behavior of Gas Mixtures

13-14C Normally yes. Air, for example, behaves as an ideal gas in the range of temperatures and pressures at which oxygen and nitrogen behave as ideal gases.

13-15C The pressure of a gas mixture is equal to the sum of the pressures each gas would exert if existed alone at the mixture temperature and volume. This law holds exactly for ideal gas mixtures, but only approximately for real gas mixtures.

13-16C The volume of a gas mixture is equal to the sum of the volumes each gas would occupy if existed alone at the mixture temperature and pressure. This law holds exactly for ideal gas mixtures, but only approximately for real gas mixtures.

13-17C The P - v - T behavior of a component in an ideal gas mixture is expressed by the ideal gas equation of state using the properties of the individual component instead of the mixture, $P_i v_i = R_i T_i$. The P - v - T behavior of a component in a real gas mixture is expressed by more complex equations of state, or by $P_i v_i = Z_i R_i T_i$, where Z_i is the compressibility factor.

13-18C Component pressure is the pressure a component would exert if existed alone at the mixture temperature and volume. Partial pressure is the quantity $y_i P_m$, where y_i is the mole fraction of component i . These two are identical for ideal gases.

13-19C Component volume is the volume a component would occupy if existed alone at the mixture temperature and pressure. Partial volume is the quantity $y_i V_m$, where y_i is the mole fraction of component i . These two are identical for ideal gases.

13-20C The one with the highest mole number.

13-21C The partial pressures will decrease but the pressure fractions will remain the same.

13-22C The partial pressures will increase but the pressure fractions will remain the same.

13-23C No. The correct expression is “the volume of a gas mixture is equal to the sum of the volumes each gas would occupy if existed alone at the mixture temperature and pressure.”

13-24C No. The correct expression is “the temperature of a gas mixture is equal to the temperature of the individual gas components.”

13-25C Yes, it is correct.

13-26 The partial pressure of R-134a in atmospheric air to form a 100-ppm contaminant is to be determined.

Analysis Noting that volume fractions and mole fractions are equal, the molar fraction of R-134a in air is

$$y_{R134a} = \frac{100}{10^6} = 0.0001$$

The partial pressure of R-134a in air is then

$$P_{R134a} = y_{R134a} P_m = (0.0001)(100 \text{ kPa}) = \mathbf{0.01 \text{ kPa}}$$

13-27 The volume fractions of components of a gas mixture are given. The mass fractions and apparent molecular weight of the mixture are to be determined.

Properties The molar masses of H₂, He, and N₂ are 2.0, 4.0, and 28.0 kg/kmol, respectively (Table A-1).

Analysis We consider 100 kmol of this mixture. Noting that volume fractions are equal to the mole fractions, mass of each component are

$$\begin{aligned} m_{H_2} &= N_{H_2} M_{H_2} = (30 \text{ kmol})(2 \text{ kg/kmol}) = 60 \text{ kg} \\ m_{He} &= N_{He} M_{He} = (40 \text{ kmol})(4 \text{ kg/kmol}) = 160 \text{ kg} \\ m_{N_2} &= N_{N_2} M_{N_2} = (30 \text{ kmol})(28 \text{ kg/kmol}) = 840 \text{ kg} \end{aligned}$$

The total mass is

$$m_m = m_{H_2} + m_{He} + m_{N_2} = 60 + 160 + 840 = 1060 \text{ kg}$$

Then the mass fractions are

$$\begin{aligned} \text{mf}_{H_2} &= \frac{m_{H_2}}{m_m} = \frac{60 \text{ kg}}{1060 \text{ kg}} = \mathbf{0.05660} \\ \text{mf}_{He} &= \frac{m_{He}}{m_m} = \frac{160 \text{ kg}}{1060 \text{ kg}} = \mathbf{0.1509} \\ \text{mf}_{N_2} &= \frac{m_{N_2}}{m_m} = \frac{840 \text{ kg}}{1060 \text{ kg}} = \mathbf{0.7925} \end{aligned}$$

<p>30% H₂ 40% He 30% N₂ (by volume)</p>

The apparent molecular weight of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{1060 \text{ kg}}{100 \text{ kmol}} = \mathbf{10.60 \text{ kg/kmol}}$$

13-28E The masses of the constituents of a gas mixture at a specified pressure and temperature are given. The partial pressure of each gas and the apparent molar mass of the gas mixture are to be determined.

Assumptions Under specified conditions both CO_2 and CH_4 can be treated as ideal gases, and the mixture as an ideal gas mixture.

Properties The molar masses of CO_2 and CH_4 are 44.0 and 16.0 lbm/lbmol, respectively (Table A-1E)

Analysis The mole numbers of gases are

$$m_{\text{CO}_2} = 1 \text{ lbm} \longrightarrow N_{\text{CO}_2} = \frac{m_{\text{CO}_2}}{M_{\text{CO}_2}} = \frac{1 \text{ lbm}}{44 \text{ lbm/lbmol}} = 0.0227 \text{ lbmol}$$

$$m_{\text{CH}_4} = 3 \text{ lbm} \longrightarrow N_{\text{CH}_4} = \frac{m_{\text{CH}_4}}{M_{\text{CH}_4}} = \frac{3 \text{ lbm}}{16 \text{ lbm/lbmol}} = 0.1875 \text{ lbmol}$$

$$N_m = N_{\text{CO}_2} + N_{\text{CH}_4} = 0.0227 \text{ lbmol} + 0.1875 \text{ lbmol} = 0.2102 \text{ lbmol}$$

$$y_{\text{CO}_2} = \frac{N_{\text{CO}_2}}{N_m} = \frac{0.0227 \text{ lbmol}}{0.2102 \text{ lbmol}} = 0.108$$

$$y_{\text{CH}_4} = \frac{N_{\text{CH}_4}}{N_m} = \frac{0.1875 \text{ lbmol}}{0.2102 \text{ lbmol}} = 0.892$$

1 lbm CO_2 3 lbm CH_4 600 R 20 psia
--

Then the partial pressures become

$$P_{\text{CO}_2} = y_{\text{CO}_2} P_m = (0.108)(20 \text{ psia}) = \mathbf{2.16 \text{ psia}}$$

$$P_{\text{CH}_4} = y_{\text{CH}_4} P_m = (0.892)(20 \text{ psia}) = \mathbf{17.84 \text{ psia}}$$

The apparent molar mass of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{4 \text{ lbm}}{0.2102 \text{ lbmol}} = \mathbf{19.03 \text{ lbm/lbmol}}$$

13-29 The volumetric fractions of the constituents of a gas mixture at a specified pressure and temperature are given. The mass fraction and partial pressure of each gas are to be determined.

Assumptions Under specified conditions all N_2 , O_2 and CO_2 can be treated as ideal gases, and the mixture as an ideal gas mixture.

Properties The molar masses of N_2 , O_2 and CO_2 are 28.0, 32.0, and 44.0 kg/kmol, respectively (Table A-1)

Analysis For convenience, consider 100 kmol of mixture. Then the mass of each component and the total mass are

$$N_{N_2} = 65 \text{ kmol} \longrightarrow m_{N_2} = N_{N_2} M_{N_2} = (65 \text{ kmol})(28 \text{ kg/kmol}) = 1820 \text{ kg}$$

$$N_{O_2} = 20 \text{ kmol} \longrightarrow m_{O_2} = N_{O_2} M_{O_2} = (20 \text{ kmol})(32 \text{ kg/kmol}) = 640 \text{ kg}$$

$$N_{CO_2} = 15 \text{ kmol} \longrightarrow m_{CO_2} = N_{CO_2} M_{CO_2} = (15 \text{ kmol})(44 \text{ kg/kmol}) = 660 \text{ kg}$$

$$m_m = m_{N_2} + m_{O_2} + m_{CO_2} = 1820 \text{ kg} + 640 \text{ kg} + 660 \text{ kg} = 3120 \text{ kg}$$

65% N_2
20% O_2
15% CO_2

350 K
300 kPa

Then the mass fraction of each component (gravimetric analysis) becomes

$$mf_{N_2} = \frac{m_{N_2}}{m_m} = \frac{1820 \text{ kg}}{3120 \text{ kg}} = 0.583 \text{ or } \mathbf{58.3\%}$$

$$mf_{O_2} = \frac{m_{O_2}}{m_m} = \frac{640 \text{ kg}}{3120 \text{ kg}} = 0.205 \text{ or } \mathbf{20.5\%}$$

$$mf_{CO_2} = \frac{m_{CO_2}}{m_m} = \frac{660 \text{ kg}}{3120 \text{ kg}} = 0.212 \text{ or } \mathbf{21.2\%}$$

For ideal gases, the partial pressure is proportional to the mole fraction, and is determined from

$$P_{N_2} = y_{N_2} P_m = (0.65)(300 \text{ kPa}) = \mathbf{195 \text{ kPa}}$$

$$P_{O_2} = y_{O_2} P_m = (0.20)(300 \text{ kPa}) = \mathbf{60 \text{ kPa}}$$

$$P_{CO_2} = y_{CO_2} P_m = (0.15)(300 \text{ kPa}) = \mathbf{45 \text{ kPa}}$$

13-30 The partial pressures of a gas mixture are given. The mole fractions, the mass fractions, the mixture molar mass, the apparent gas constant, the constant-volume specific heat, and the specific heat ratio are to be determined.

Properties The molar masses of CO₂, O₂ and N₂ are 44.0, 32.0, and 28.0 kg/kmol, respectively (Table A-1). The constant-volume specific heats of these gases at 300 K are 0.657, 0.658, and 0.743 kJ/kg·K, respectively (Table A-2a).

Analysis The total pressure is

$$P_{\text{total}} = P_{\text{CO}_2} + P_{\text{O}_2} + P_{\text{N}_2} = 20 + 30 + 50 = 100 \text{ kPa}$$

The volume fractions are equal to the pressure fractions. Then,

$$y_{\text{CO}_2} = \frac{P_{\text{CO}_2}}{P_{\text{total}}} = \frac{20}{100} = \mathbf{0.20}$$

$$y_{\text{O}_2} = \frac{P_{\text{O}_2}}{P_{\text{total}}} = \frac{30}{100} = \mathbf{0.30}$$

$$y_{\text{N}_2} = \frac{P_{\text{N}_2}}{P_{\text{total}}} = \frac{50}{100} = \mathbf{0.50}$$

Partial pressures
CO₂, 20 kPa
O₂, 30 kPa
N₂, 50 kPa

We consider 100 kmol of this mixture. Then the mass of each component are

$$m_{\text{CO}_2} = N_{\text{CO}_2} M_{\text{CO}_2} = (20 \text{ kmol})(44 \text{ kg/kmol}) = 880 \text{ kg}$$

$$m_{\text{O}_2} = N_{\text{O}_2} M_{\text{O}_2} = (30 \text{ kmol})(32 \text{ kg/kmol}) = 960 \text{ kg}$$

$$m_{\text{N}_2} = N_{\text{N}_2} M_{\text{N}_2} = (50 \text{ kmol})(28 \text{ kg/kmol}) = 1400 \text{ kg}$$

The total mass is

$$m_m = m_{\text{N}_2} + m_{\text{O}_2} + m_{\text{Ar}} = 880 + 960 + 1400 = 3240 \text{ kg}$$

Then the mass fractions are

$$\text{mf}_{\text{CO}_2} = \frac{m_{\text{CO}_2}}{m_m} = \frac{880 \text{ kg}}{3240 \text{ kg}} = \mathbf{0.2716}$$

$$\text{mf}_{\text{O}_2} = \frac{m_{\text{O}_2}}{m_m} = \frac{960 \text{ kg}}{3240 \text{ kg}} = \mathbf{0.2963}$$

$$\text{mf}_{\text{N}_2} = \frac{m_{\text{N}_2}}{m_m} = \frac{1400 \text{ kg}}{3240 \text{ kg}} = \mathbf{0.4321}$$

The apparent molecular weight of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{3240 \text{ kg}}{100 \text{ kmol}} = \mathbf{32.40 \text{ kg/kmol}}$$

The constant-volume specific heat of the mixture is determined from

$$\begin{aligned} c_v &= \text{mf}_{\text{CO}_2} c_{v,\text{CO}_2} + \text{mf}_{\text{O}_2} c_{v,\text{O}_2} + \text{mf}_{\text{N}_2} c_{v,\text{N}_2} \\ &= 0.2716 \times 0.657 + 0.2963 \times 0.658 + 0.4321 \times 0.743 \\ &= \mathbf{0.6945 \text{ kJ/kg} \cdot \text{K}} \end{aligned}$$

The apparent gas constant of the mixture is

$$R = \frac{R_u}{M_m} = \frac{8.314 \text{ kJ/kmol} \cdot \text{K}}{32.40 \text{ kg/kmol}} = \mathbf{0.2566 \text{ kJ/kg} \cdot \text{K}}$$

The constant-pressure specific heat of the mixture and the specific heat ratio are

$$c_p = c_v + R = 0.6945 + 0.2566 = \mathbf{0.9511 \text{ kJ/kg} \cdot \text{K}}$$

$$k = \frac{c_p}{c_v} = \frac{0.9511 \text{ kJ/kg} \cdot \text{K}}{0.6945 \text{ kJ/kg} \cdot \text{K}} = \mathbf{1.370}$$

13-31 An additional 5% of oxygen is mixed with standard atmospheric air. The molecular weight of this mixture is to be determined.

Properties The molar masses of N_2 and O_2 are 28.0 and 32.0 kg/kmol, respectively (Table A-1).

Analysis Standard air is taken as 79% nitrogen and 21% oxygen by mole. That is,

$$y_{O_2} = 0.21$$

$$y_{N_2} = 0.79$$

Adding another 0.05 moles of O_2 to 1 kmol of standard air gives

$$y_{O_2} = \frac{0.26}{1.05} = 0.2476$$

$$y_{N_2} = \frac{0.79}{1.05} = 0.7524$$

Then,

$$M_m = y_{O_2}M_{O_2} + y_{N_2}M_{N_2} = 0.2476 \times 32 + 0.7524 \times 28 = \mathbf{28.99 \text{ kg/kmol}}$$

13-32 The masses, temperatures, and pressures of two gases contained in two tanks connected to each other are given. The valve connecting the tanks is opened and the final temperature is measured. The volume of each tank and the final pressure are to be determined.

Assumptions Under specified conditions both N_2 and O_2 can be treated as ideal gases, and the mixture as an ideal gas mixture

Properties The molar masses of N_2 and O_2 are 28.0 and 32.0 kg/kmol, respectively. The gas constants of N_2 and O_2 are 0.2968 and 0.2598 kPa·m³/kg·K, respectively (Table A-1).

Analysis The volumes of the tanks are

$$V_{N_2} = \left(\frac{mRT}{P} \right)_{N_2} = \frac{(2 \text{ kg})(0.2968 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(298 \text{ K})}{550 \text{ kPa}} = \mathbf{0.322 \text{ m}^3}$$

$$V_{O_2} = \left(\frac{mRT}{P} \right)_{O_2} = \frac{(4 \text{ kg})(0.2598 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(298 \text{ K})}{150 \text{ kPa}} = \mathbf{2.065 \text{ m}^3}$$

$$V_{\text{total}} = V_{N_2} + V_{O_2} = 0.322 \text{ m}^3 + 2.065 \text{ m}^3 = 2.386 \text{ m}^3$$

Also,

$$N_{N_2} = \frac{m_{N_2}}{M_{N_2}} = \frac{2 \text{ kg}}{28 \text{ kg/kmol}} = 0.07143 \text{ kmol}$$

$$N_{O_2} = \frac{m_{O_2}}{M_{O_2}} = \frac{4 \text{ kg}}{32 \text{ kg/kmol}} = 0.125 \text{ kmol}$$

$$N_m = N_{N_2} + N_{O_2} = 0.07143 \text{ kmol} + 0.125 \text{ kmol} = 0.1964 \text{ kmol}$$

Thus,

$$P_m = \left(\frac{NR_u T}{V} \right)_m = \frac{(0.1964 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(298 \text{ K})}{2.386 \text{ m}^3} = \mathbf{204 \text{ kPa}}$$

13-33 The masses of components of a gas mixture are given. The apparent molecular weight of this mixture, the volume it occupies, the partial volume of the oxygen, and the partial pressure of the helium are to be determined.

Properties The molar masses of O₂, CO₂, and He are 32.0, 44.0, and 4.0 kg/kmol, respectively (Table A-1).

Analysis The total mass of the mixture is

$$m_m = m_{\text{O}_2} + m_{\text{CO}_2} + m_{\text{He}} = 0.4 + 0.7 + 0.2 = 1.3 \text{ kg}$$

The mole numbers of each component are

$$N_{\text{O}_2} = \frac{m_{\text{O}_2}}{M_{\text{O}_2}} = \frac{0.4 \text{ kg}}{32 \text{ kg/kmol}} = 0.01250 \text{ kmol}$$

$$N_{\text{CO}_2} = \frac{m_{\text{CO}_2}}{M_{\text{CO}_2}} = \frac{0.7 \text{ kg}}{44 \text{ kg/kmol}} = 0.01591 \text{ kmol}$$

$$N_{\text{He}} = \frac{m_{\text{He}}}{M_{\text{He}}} = \frac{0.2 \text{ kg}}{4 \text{ kg/kmol}} = 0.05 \text{ kmol}$$

0.4 kg O ₂ 0.7 kg CO ₂ 0.2 kg He
--

The mole number of the mixture is

$$N_m = N_{\text{O}_2} + N_{\text{CO}_2} + N_{\text{He}} = 0.01250 + 0.01591 + 0.05 = 0.07841 \text{ kmol}$$

Then the apparent molecular weight of the mixture becomes

$$M_m = \frac{m_m}{N_m} = \frac{1.3 \text{ kg}}{0.07841 \text{ kmol}} = \mathbf{16.58 \text{ kg/kmol}}$$

The volume of this ideal gas mixture is

$$V_m = \frac{N_m R_u T}{P} = \frac{(0.07841 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(300 \text{ K})}{100 \text{ kPa}} = \mathbf{1.956 \text{ m}^3}$$

The partial volume of oxygen in the mixture is

$$V_{\text{O}_2} = y_{\text{O}_2} V_m = \frac{N_{\text{O}_2}}{N_m} V_m = \frac{0.01250 \text{ kmol}}{0.07841 \text{ kmol}} (1.956 \text{ m}^3) = \mathbf{0.3118 \text{ m}^3}$$

The partial pressure of helium in the mixture is

$$P_{\text{He}} = y_{\text{He}} P_m = \frac{N_{\text{He}}}{N_m} P_m = \frac{0.05 \text{ kmol}}{0.07841 \text{ kmol}} (100 \text{ kPa}) = \mathbf{63.77 \text{ kPa}}$$

13-34 The mass fractions of components of a gas mixture are given. The volume occupied by 100 kg of this mixture is to be determined.

Properties The molar masses of CH_4 , C_3H_8 , and C_4H_{10} are 16.0, 44.0, and 58.0 kg/kmol, respectively (Table A-1).

Analysis The mole numbers of each component are

$$N_{\text{CH}_4} = \frac{m_{\text{CH}_4}}{M_{\text{CH}_4}} = \frac{60 \text{ kg}}{16 \text{ kg/kmol}} = 3.75 \text{ kmol}$$

$$N_{\text{C}_3\text{H}_8} = \frac{m_{\text{C}_3\text{H}_8}}{M_{\text{C}_3\text{H}_8}} = \frac{25 \text{ kg}}{44 \text{ kg/kmol}} = 0.5682 \text{ kmol}$$

$$N_{\text{C}_4\text{H}_{10}} = \frac{m_{\text{C}_4\text{H}_{10}}}{M_{\text{C}_4\text{H}_{10}}} = \frac{15 \text{ kg}}{58 \text{ kg/kmol}} = 0.2586 \text{ kmol}$$

60% CH_4 25% C_3H_8 15% C_4H_{10} (by mass)

The mole number of the mixture is

$$N_m = N_{\text{CH}_4} + N_{\text{C}_3\text{H}_8} + N_{\text{C}_4\text{H}_{10}} = 3.75 + 0.5682 + 0.2586 = 4.5768 \text{ kmol}$$

The apparent molecular weight of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{100 \text{ kg}}{4.5768 \text{ kmol}} = 21.85 \text{ kg/kmol}$$

Then the volume of this ideal gas mixture is

$$V_m = \frac{N_m R_u T}{P} = \frac{(4.5768 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(310 \text{ K})}{3000 \text{ kPa}} = \mathbf{3.93 \text{ m}^3}$$

13-35 A tank contains a mixture of two gases of known masses at a specified pressure and temperature. The volume of the tank is to be determined.

Assumptions Under specified conditions both O_2 and CO_2 can be treated as ideal gases, and the mixture as an ideal gas mixture.

Analysis The total number of moles is

$$N_m = N_{\text{O}_2} + N_{\text{CO}_2} = 8 \text{ kmol} + 10 \text{ kmol} = 18 \text{ kmol}$$

Then

$$V_m = \frac{N_m R_u T_m}{P_m} = \frac{(18 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(290 \text{ K})}{150 \text{ kPa}} = \mathbf{289.3 \text{ m}^3}$$

8 kmol O_2 10 kmol CO_2

400 K
150 kPa

13-37 The mass fractions of components of a gas mixture are given. The partial pressure of ethane is to be determined.

Properties The molar masses of CH_4 and C_2H_6 are 16.0 and 30.0 kg/kmol, respectively (Table A-1).

Analysis We consider 100 kg of this mixture. The mole numbers of each component are

$$N_{CH_4} = \frac{m_{CH_4}}{M_{CH_4}} = \frac{70 \text{ kg}}{16 \text{ kg/kmol}} = 4.375 \text{ kmol}$$

$$N_{C_2H_6} = \frac{m_{C_2H_6}}{M_{C_2H_6}} = \frac{30 \text{ kg}}{30 \text{ kg/kmol}} = 1.0 \text{ kmol}$$

The mole number of the mixture is

$$N_m = N_{CH_4} + N_{C_2H_6} = 4.375 + 1.0 = 5.375 \text{ kmol}$$

The mole fractions are

$$y_{CH_4} = \frac{N_{CH_4}}{N_m} = \frac{4.375 \text{ kmol}}{5.375 \text{ kmol}} = 0.8139$$

$$y_{C_2H_6} = \frac{N_{C_2H_6}}{N_m} = \frac{1.0 \text{ kmol}}{5.375 \text{ kmol}} = 0.1861$$

The final pressure of ethane in the final mixture is

$$P_{C_2H_6} = y_{C_2H_6} P_m = (0.1861)(130 \text{ kPa}) = \mathbf{24.19 \text{ kPa}}$$

70% CH_4
30% C_2H_6
(by mass)
100 m^3
130 kPa, 25°C

13-38E A mixture consists of liquid water and another fluid. The specific weight of this mixture is to be determined.

Properties The densities of water and the fluid are given to be 62.4 lbf/ft^3 and 50.0 lbf/ft^3 , respectively.

Analysis We consider 1 ft^3 of this mixture. The volume of the water in the mixture is 0.35 ft^3 which has a mass of

$$m_w = \rho_w \mathcal{V}_w = (62.4 \text{ lbf/ft}^3)(0.35 \text{ ft}^3) = 21.84 \text{ lbfm}$$

The weight of this water is

$$W_w = m_w g = (21.84 \text{ lbfm})(31.9 \text{ ft/s}^2) \left(\frac{1 \text{ lbf}}{32.174 \text{ lbfm} \cdot \text{ft/s}^2} \right) = 21.65 \text{ lbf}$$

Similarly, the volume of the second fluid is 0.65 ft^3 , and the mass of this fluid is

$$m_f = \rho_f \mathcal{V}_f = (50 \text{ lbf/ft}^3)(0.65 \text{ ft}^3) = 32.50 \text{ lbfm}$$

The weight of the fluid is

$$W_f = m_f g = (32.50 \text{ lbfm})(31.9 \text{ ft/s}^2) \left(\frac{1 \text{ lbf}}{32.174 \text{ lbfm} \cdot \text{ft/s}^2} \right) = 32.22 \text{ lbf}$$

The specific weight of this mixture is then

$$\gamma = \frac{W_w + W_f}{\mathcal{V}_w + \mathcal{V}_f} = \frac{(21.65 + 32.22) \text{ lbf}}{(0.35 + 0.65) \text{ ft}^3} = \mathbf{53.9 \text{ lbf/ft}^3}$$

<p>0.35 ft³ water 0.65 ft³ fluid</p>

13-39 The mole fractions of components of a gas mixture are given. The mass flow rate of the mixture is to be determined.

Properties The molar masses of air and CH_4 are 28.97 and 16.0 kg/kmol , respectively (Table A-1).

Analysis The molar fraction of air is

$$y_{\text{air}} = 1 - y_{\text{CH}_4} = 1 - 0.15 = 0.85$$

The molar mass of the mixture is determined from

$$\begin{aligned} M_m &= y_{\text{CH}_4} M_{\text{CH}_4} + y_{\text{air}} M_{\text{air}} \\ &= 0.15 \times 16 + 0.85 \times 28.97 \\ &= 27.02 \text{ kg/kmol} \end{aligned}$$

<p>15% CH_4 85% air (by mole)</p>
--

Given the engine displacement and speed and assuming that this is a 4-stroke engine (2 revolutions per cycle), the volume flow rate is determined from

$$\dot{\mathcal{V}} = \frac{\dot{n} \mathcal{V}_d}{2} = \frac{(3000 \text{ rev/min})(0.005 \text{ m}^3)}{2 \text{ rev/cycle}} = 7.5 \text{ m}^3/\text{min}$$

The specific volume of the mixture is

$$\nu = \frac{R_u T}{M_m P} = \frac{(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(293 \text{ K})}{(27.02 \text{ kg/kmol})(80 \text{ kPa})} = 1.127 \text{ m}^3/\text{kg}$$

Hence the mass flow rate is

$$\dot{m} = \frac{\dot{\mathcal{V}}}{\nu} = \frac{7.5 \text{ m}^3/\text{min}}{1.127 \text{ m}^3/\text{kg}} = \mathbf{6.65 \text{ kg/min}}$$

13-40E The volumetric fractions of components of a natural gas mixture are given. The mass and volume flow rates of the mixture are to be determined.

Properties The molar masses of CH_4 and C_2H_6 are 16.0 and 30.0 lbm/lbmol, respectively (Table A-1E).

Analysis The molar mass of the mixture is determined from

$$M_m = y_{\text{CH}_4}M_{\text{CH}_4} + y_{\text{C}_2\text{H}_6}M_{\text{C}_2\text{H}_6} = 0.95 \times 16 + 0.05 \times 30 = 16.70 \text{ lbm/lbmol}$$

The specific volume of the mixture is

$$v = \frac{R_u T}{M_m P} = \frac{(10.73 \text{ psia} \cdot \text{ft}^3/\text{lbmol} \cdot \text{R})(520 \text{ R})}{(16.70 \text{ lbm/lbmol})(100 \text{ psia})} = 3.341 \text{ ft}^3/\text{lbm}$$

→	95% CH_4 5% C_2H_6 (by volume)
---	---

The volume flow rate is

$$\dot{V} = AV = \frac{\pi D^2}{4} V = \frac{\pi (36/12 \text{ ft})^2}{4} (10 \text{ ft/s}) = \mathbf{70.69 \text{ ft}^3/\text{s}}$$

and the mass flow rate is

$$\dot{m} = \frac{\dot{V}}{v} = \frac{70.69 \text{ ft}^3/\text{s}}{3.341 \text{ ft}^3/\text{lbm}} = \mathbf{21.16 \text{ lbm/s}}$$

13-41E The mass fractions of gases forming a mixture at a specified pressure and temperature are given. The mass of the gas mixture is to be determined using four methods.

Properties The molar masses of CH_4 and C_2H_6 are 16.0 and 30.0 lbm/lbmol, respectively (Table A-1E).

Analysis (a) We consider 100 lbm of this mixture. Then the mole numbers of each component are

$$N_{\text{CH}_4} = \frac{m_{\text{CH}_4}}{M_{\text{CH}_4}} = \frac{75 \text{ lbm}}{16 \text{ lbm/lbmol}} = 4.6875 \text{ lbmol}$$

$$N_{\text{C}_2\text{H}_6} = \frac{m_{\text{C}_2\text{H}_6}}{M_{\text{C}_2\text{H}_6}} = \frac{25 \text{ lbm}}{30 \text{ lbm/lbmol}} = 0.8333 \text{ lbmol}$$

The mole number of the mixture and the mole fractions are

$$N_m = 4.6875 + 0.8333 = 5.5208 \text{ lbmol}$$

$$y_{\text{CH}_4} = \frac{N_{\text{CH}_4}}{N_m} = \frac{4.6875 \text{ lbmol}}{5.5208 \text{ lbmol}} = 0.8491$$

$$y_{\text{C}_2\text{H}_6} = \frac{N_{\text{C}_2\text{H}_6}}{N_m} = \frac{0.8333 \text{ lbmol}}{5.5208 \text{ lbmol}} = 0.1509$$

75% CH_4
25% C_2H_6
(by mass)
2000 psia
300°F

Then the apparent molecular weight of the mixture becomes

$$M_m = \frac{m_m}{N_m} = \frac{100 \text{ lbm}}{5.5208 \text{ lbmol}} = 18.11 \text{ lbm/lbmol}$$

The apparent gas constant of the mixture is

$$R = \frac{R_u}{M_m} = \frac{10.73 \text{ psia} \cdot \text{ft}^3/\text{lbmol} \cdot \text{R}}{18.11 \text{ lbm/lbmol}} = 0.5925 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R}$$

The mass of this mixture in a 1 million ft^3 tank is

$$m = \frac{P\mathcal{V}}{RT} = \frac{(2000 \text{ psia})(1 \times 10^6 \text{ ft}^3)}{(0.5925 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(760 \text{ R})} = \mathbf{4.441 \times 10^6 \text{ lbm}}$$

(b) To use the Amagat's law for this real gas mixture, we first need the compressibility factor of each component at the mixture temperature and pressure. The compressibility factors are obtained using Fig. A-15 to be

$$\left. \begin{aligned} T_{R,\text{CH}_4} &= \frac{T_m}{T_{\text{cr},\text{CH}_4}} = \frac{760 \text{ R}}{343.9 \text{ R}} = 2.210 \\ P_{R,\text{CH}_4} &= \frac{P_m}{P_{\text{cr},\text{CH}_4}} = \frac{2000 \text{ psia}}{673 \text{ psia}} = 2.972 \end{aligned} \right\} Z_{\text{CH}_4} = 0.98$$

$$\left. \begin{aligned} T_{R,\text{C}_2\text{H}_6} &= \frac{760 \text{ R}}{549.8 \text{ R}} = 1.382 \\ P_{R,\text{C}_2\text{H}_6} &= \frac{1500 \text{ psia}}{708 \text{ psia}} = 2.119 \end{aligned} \right\} Z_{\text{C}_2\text{H}_6} = 0.77$$

Then,

$$Z_m = \sum y_i Z_i = y_{\text{CH}_4} Z_{\text{CH}_4} + y_{\text{C}_2\text{H}_6} Z_{\text{C}_2\text{H}_6} = (0.8491)(0.98) + (0.1509)(0.77) = 0.9483$$

$$m = \frac{P\mathcal{V}}{Z_m RT} = \frac{(2000 \text{ psia})(1 \times 10^6 \text{ ft}^3)}{(0.9483)(0.5925 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(760 \text{ R})} = \mathbf{4.684 \times 10^6 \text{ lbm}}$$

(c) To use Dalton's law with compressibility factors: (Fig. A-15)

$$\left. \begin{aligned} T_{R,\text{CH}_4} &= 2.210 \\ \nu_{R,\text{CH}_4} &= \frac{\nu_m/m_{\text{CH}_4}}{R_{\text{CH}_4} T_{\text{cr},\text{CH}_4} / P_{\text{cr},\text{CH}_4}} = \frac{(1 \times 10^6 \text{ ft}^3)/(4.441 \times 10^6 \times 0.75 \text{ lbm})}{(0.6688 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(343.9 \text{ R})/(673 \text{ psia})} = 0.8782 \end{aligned} \right\} Z_{\text{CH}_4} = 0.98$$

$$T_{R,C_2H_6} = 1.382$$

$$\nu_{R,C_2H_6} = \frac{\mathcal{V}_m/m_{C_2H_6}}{RT_{cr,C_2H_6}/P_{cr,C_2H_6}} = \frac{(1 \times 10^6 \text{ ft}^3)/(4.441 \times 10^6 \times 0.25 \text{ lbm})}{(0.3574 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(549.8 \text{ R})/(708 \text{ psia})} = 3.244 \quad \left. \vphantom{\nu_{R,C_2H_6}} \right\} Z_{CH_4} = 0.92$$

Note that we used $m = 4.441 \times 10^6 \times 0.25 \text{ lbm}$ in above calculations, the value obtained by ideal gas behavior. The solution normally requires iteration until the assumed and calculated mass values match. The mass of the component gas is obtained by multiplying the mass of the mixture by its mass fraction. Then,

$$Z_m = \sum y_i Z_i = y_{CH_4} Z_{CH_4} + y_{C_2H_6} Z_{C_2H_6} = (0.8491)(0.98) + (0.1509)(0.92) = 0.9709$$

$$m = \frac{P\mathcal{V}}{Z_m RT} = \frac{(2000 \text{ psia})(1 \times 10^6 \text{ ft}^3)}{(0.9709)(0.5925 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(760 \text{ R})} = \mathbf{4.575 \times 10^6 \text{ lbm}}$$

This mass is sufficiently close to the assumed mass value of $4.441 \times 10^6 \times 0.25 \text{ lbm}$. Therefore, there is no need to repeat the calculations at this calculated mass.

(d) To use Kay's rule, we need to determine the pseudo-critical temperature and pseudo-critical pressure of the mixture using the critical point properties of gases.

$$T'_{cr,m} = \sum y_i T_{cr,i} = y_{CH_4} T_{cr,CH_4} + y_{C_2H_6} T_{cr,C_2H_6}$$

$$= (0.8491)(343.9 \text{ R}) + (0.1509)(549.8 \text{ R})$$

$$= 375.0 \text{ R}$$

$$P'_{cr,m} = \sum y_i P_{cr,i} = y_{CH_4} P_{cr,CH_4} + y_{C_2H_6} P_{cr,C_2H_6}$$

$$= (0.8491)(673 \text{ psia}) + (0.1509)(708 \text{ psia})$$

$$= 678.3 \text{ psia}$$

Then,

$$T_R = \frac{T_m}{T'_{cr,m}} = \frac{760 \text{ R}}{375.0 \text{ R}} = 2.027$$

$$P_R = \frac{P_m}{P'_{cr,m}} = \frac{2000 \text{ psia}}{678.3 \text{ psia}} = 2.949 \quad \left. \vphantom{P_R} \right\} Z_m = 0.97 \quad (\text{Fig. A-15})$$

$$m = \frac{P\mathcal{V}}{Z_m RT} = \frac{(2000 \text{ psia})(1 \times 10^6 \text{ ft}^3)}{(0.97)(0.5925 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(760 \text{ R})} = \mathbf{4.579 \times 10^6 \text{ lbm}}$$

13-42 The volumetric analysis of a mixture of gases is given. The volumetric and mass flow rates are to be determined using three methods.

Properties The molar masses of O₂, N₂, CO₂, and CH₄ are 32.0, 28.0, 44.0, and 16.0 kg/kmol, respectively (Table A-1).

Analysis (a) We consider 100 kmol of this mixture. Noting that volume fractions are equal to the mole fractions, mass of each component are

$$\begin{aligned} m_{\text{O}_2} &= N_{\text{O}_2} M_{\text{O}_2} = (30 \text{ kmol})(32 \text{ kg/kmol}) = 960 \text{ kg} \\ m_{\text{N}_2} &= N_{\text{N}_2} M_{\text{N}_2} = (40 \text{ kmol})(28 \text{ kg/kmol}) = 1120 \text{ kg} \\ m_{\text{CO}_2} &= N_{\text{CO}_2} M_{\text{CO}_2} = (10 \text{ kmol})(44 \text{ kg/kmol}) = 440 \text{ kg} \\ m_{\text{CH}_4} &= N_{\text{CH}_4} M_{\text{CH}_4} = (20 \text{ kmol})(16 \text{ kg/kmol}) = 320 \text{ kg} \end{aligned}$$

The total mass is

$$\begin{aligned} m_m &= m_{\text{O}_2} + m_{\text{N}_2} + m_{\text{CO}_2} + m_{\text{CH}_4} \\ &= 960 + 1120 + 440 + 320 \\ &= 2840 \text{ kg} \end{aligned}$$

The apparent molecular weight of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{2840 \text{ kg}}{100 \text{ kmol}} = 28.40 \text{ kg/kmol}$$

The apparent gas constant of the mixture is

$$R = \frac{R_u}{M_m} = \frac{8.314 \text{ kJ/kmol} \cdot \text{K}}{28.40 \text{ kg/kmol}} = 0.2927 \text{ kJ/kg} \cdot \text{K}$$

The specific volume of the mixture is

$$\nu = \frac{RT}{P} = \frac{(0.2927 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(288 \text{ K})}{8000 \text{ kPa}} = 0.01054 \text{ m}^3/\text{kg}$$

The volume flow rate is

$$\dot{V} = AV = \frac{\pi D^2}{4} V = \frac{\pi(0.016 \text{ m})^2}{4} (5 \text{ m/s}) = \mathbf{0.001005 \text{ m}^3/\text{s}}$$

and the mass flow rate is

$$\dot{m} = \frac{\dot{V}}{\nu} = \frac{0.001005 \text{ m}^3/\text{s}}{0.01054 \text{ m}^3/\text{kg}} = \mathbf{0.09535 \text{ kg/s}}$$

(b) To use the Amagat's law for this real gas mixture, we first need the mole fractions and the Z of each component at the mixture temperature and pressure. The compressibility factors are obtained using Fig. A-15 to be

$$\left. \begin{aligned} T_{R,\text{O}_2} &= \frac{T_m}{T_{\text{cr},\text{O}_2}} = \frac{288 \text{ K}}{154.8 \text{ K}} = 1.860 \\ P_{R,\text{O}_2} &= \frac{P_m}{P_{\text{cr},\text{O}_2}} = \frac{8 \text{ MPa}}{5.08 \text{ MPa}} = 1.575 \end{aligned} \right\} Z_{\text{O}_2} = 0.95$$

$$\left. \begin{aligned} T_{R,\text{N}_2} &= \frac{288 \text{ K}}{126.2 \text{ K}} = 2.282 \\ P_{R,\text{N}_2} &= \frac{8 \text{ MPa}}{3.39 \text{ MPa}} = 2.360 \end{aligned} \right\} Z_{\text{N}_2} = 0.99$$

$$\left. \begin{aligned} T_{R,\text{CO}_2} &= \frac{288 \text{ K}}{304.2 \text{ K}} = 0.947 \\ P_{R,\text{CO}_2} &= \frac{8 \text{ MPa}}{7.39 \text{ MPa}} = 1.083 \end{aligned} \right\} Z_{\text{CO}_2} = 0.199$$

$$\left. \begin{aligned} T_{R,\text{CH}_4} &= \frac{288 \text{ K}}{191.1 \text{ K}} = 1.507 \\ P_{R,\text{CH}_4} &= \frac{8 \text{ MPa}}{4.64 \text{ MPa}} = 1.724 \end{aligned} \right\} Z_{\text{CH}_4} = 0.85$$

and

$$\begin{aligned}
 Z_m &= \sum y_i Z_i = y_{O_2} Z_{O_2} + y_{N_2} Z_{N_2} + y_{CO_2} Z_{CO_2} + y_{CH_4} Z_{CH_4} \\
 &= (0.30)(0.95) + (0.40)(0.99) + (0.10)(0.199) + (0.20)(0.85) \\
 &= 0.8709
 \end{aligned}$$

Then,

$$\nu = \frac{Z_m RT}{P} = \frac{(0.8709)(0.2927 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(288 \text{ K})}{8000 \text{ kPa}} = 0.009178 \text{ m}^3/\text{kg}$$

$$\dot{\nu} = 0.001005 \text{ m}^3/\text{s}$$

$$\dot{m} = \frac{\dot{\nu}}{\nu} = \frac{0.001005 \text{ m}^3/\text{s}}{0.009178 \text{ m}^3/\text{kg}} = 0.1095 \text{ kg/s}$$

(c) To use Kay's rule, we need to determine the pseudo-critical temperature and pseudo-critical pressure of the mixture using the critical point properties of mixture gases.

$$\begin{aligned}
 T'_{cr,m} &= \sum y_i T_{cr,i} = y_{O_2} T_{cr,O_2} + y_{N_2} T_{cr,N_2} + y_{CO_2} T_{cr,CO_2} + y_{CH_4} T_{cr,CH_4} \\
 &= (0.30)(154.8 \text{ K}) + (0.40)(126.2 \text{ K}) + (0.10)(304.2 \text{ K}) + (0.20)(191.1 \text{ K}) \\
 &= 165.6 \text{ K}
 \end{aligned}$$

$$\begin{aligned}
 P'_{cr,m} &= \sum y_i P_{cr,i} = y_{O_2} P_{cr,O_2} + y_{N_2} P_{cr,N_2} + y_{CO_2} P_{cr,CO_2} + y_{CH_4} P_{cr,CH_4} \\
 &= (0.30)(5.08 \text{ MPa}) + (0.40)(3.39 \text{ MPa}) + (0.10)(7.39 \text{ MPa}) + (0.20)(4.64 \text{ MPa}) \\
 &= 4.547 \text{ MPa}
 \end{aligned}$$

and

$$\left. \begin{aligned}
 T_R &= \frac{T_m}{T'_{cr,m}} = \frac{288 \text{ K}}{165.6 \text{ K}} = 1.739 \\
 P_R &= \frac{P_m}{P'_{cr,m}} = \frac{8 \text{ MPa}}{4.547 \text{ MPa}} = 1.759
 \end{aligned} \right\} Z_m = 0.92 \quad (\text{Fig. A-15})$$

Then,

$$\nu = \frac{Z_m RT}{P} = \frac{(0.92)(0.2927 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(288 \text{ K})}{8000 \text{ kPa}} = 0.009694 \text{ m}^3/\text{kg}$$

$$\dot{\nu} = 0.001005 \text{ m}^3/\text{s}$$

$$\dot{m} = \frac{\dot{\nu}}{\nu} = \frac{0.001005 \text{ m}^3/\text{s}}{0.009694 \text{ m}^3/\text{kg}} = 0.1037 \text{ kg/s}$$

13-43E The mole numbers, temperatures, and pressures of two gases forming a mixture are given. For a specified final temperature, the pressure of the mixture is to be determined using two methods.

Properties The critical properties of Ar are $T_{cr} = 272$ R and $P_{cr} = 705$ psia. The critical properties of N_2 are $T_{cr} = 227.1$ R and $P_{cr} = 492$ psia (Table A-1E).

Analysis (a) Under specified conditions both Ar and N_2 will considerably deviate from the ideal gas behavior. Treating the mixture as an ideal gas,

$$\left. \begin{array}{l} \text{Initial state: } P_1 V_1 = N_1 R_u T_1 \\ \text{Final state: } P_2 V_2 = N_2 R_u T_2 \end{array} \right\} P_2 = \frac{N_2 T_2}{N_1 T_1} P_1 = \frac{(4)(360 \text{ R})}{(1)(400 \text{ R})} (750 \text{ psia}) = \mathbf{2700 \text{ psia}}$$

(b) Initially,

$$\left. \begin{array}{l} T_R = \frac{T_1}{T_{cr,Ar}} = \frac{400 \text{ R}}{272 \text{ R}} = 1.47 \\ P_R = \frac{P_1}{P_{cr,Ar}} = \frac{750 \text{ psia}}{705 \text{ psia}} = 1.07 \end{array} \right\} Z_{Ar} = 0.90 \text{ (Fig. A-15)}$$

Then the volume of the tank is

$$V = \frac{Z N_{Ar} R_u T}{P} = \frac{(0.90)(1 \text{ lbmol})(10.73 \text{ psia} \cdot \text{ft}^3/\text{lbmol} \cdot \text{R})(400 \text{ R})}{750 \text{ psia}} = 5.15 \text{ ft}^3$$

After mixing,

$$\left. \begin{array}{l} T_{R,Ar} = \frac{T_m}{T_{cr,Ar}} = \frac{360 \text{ R}}{272 \text{ R}} = 1.324 \\ \nu_{R,Ar} = \frac{\nu_{Ar}}{R_u T_{cr,Ar} / P_{cr,Ar}} = \frac{\nu_m / N_{Ar}}{R_u T_{cr,Ar} / P_{cr,Ar}} \\ = \frac{(5.15 \text{ ft}^3)/(1 \text{ lbmol})}{(10.73 \text{ psia} \cdot \text{ft}^3/\text{lbmol} \cdot \text{R})(272 \text{ R})/(705 \text{ psia})} = 1.244 \end{array} \right\} P_R = 0.82 \text{ (Fig. A-15)}$$

$$\left. \begin{array}{l} T_{R,N_2} = \frac{T_m}{T_{cr,N_2}} = \frac{360 \text{ R}}{227.1 \text{ R}} = 1.585 \\ \nu_{R,N_2} = \frac{\nu_{N_2}}{R_u T_{cr,N_2} / P_{cr,N_2}} = \frac{\nu_m / N_{N_2}}{R_u T_{cr,N_2} / P_{cr,N_2}} \\ = \frac{(5.15 \text{ ft}^3)/(3 \text{ lbmol})}{(10.73 \text{ psia} \cdot \text{ft}^3/\text{lbmol} \cdot \text{R})(227.1 \text{ R})/(492 \text{ psia})} = 0.347 \end{array} \right\} P_R = 3.85 \text{ (Fig. A-15)}$$

Thus,

$$P_{Ar} = (P_R P_{cr})_{Ar} = (0.82)(705 \text{ psia}) = 578 \text{ psia}$$

$$P_{N_2} = (P_R P_{cr})_{N_2} = (3.85)(492 \text{ psia}) = 1894 \text{ psia}$$

and

$$P_m = P_{Ar} + P_{N_2} = 578 \text{ psia} + 1894 \text{ psia} = \mathbf{2472 \text{ psia}}$$

Properties of Gas Mixtures

13-44C Yes. Yes (extensive property).

13-45C No (intensive property).

13-46C The answers are the same for entropy.

13-47C Yes. Yes (conservation of energy).

13-48C We have to use the partial pressure.

13-49C No, this is an approximate approach. It assumes a component behaves as if it existed alone at the mixture temperature and pressure (i.e., it disregards the influence of dissimilar molecules on each other.)

13-50 The volume fractions of components of a gas mixture are given. This mixture is heated while flowing through a tube at constant pressure. The heat transfer to the mixture per unit mass of the mixture is to be determined.

Assumptions All gases will be modeled as ideal gases with constant specific heats.

Properties The molar masses of O₂, N₂, CO₂, and CH₄ are 32.0, 28.0, 44.0, and 16.0 kg/kmol, respectively (Table A-1). The constant-pressure specific heats of these gases at room temperature are 0.918, 1.039, 0.846, and 2.2537 kJ/kg·K, respectively (Table A-2a).

Analysis We consider 100 kmol of this mixture. Noting that volume fractions are equal to the mole fractions, mass of each component are

$$\begin{aligned} m_{\text{O}_2} &= N_{\text{O}_2} M_{\text{O}_2} = (30 \text{ kmol})(32 \text{ kg/kmol}) = 960 \text{ kg} \\ m_{\text{N}_2} &= N_{\text{N}_2} M_{\text{N}_2} = (40 \text{ kmol})(28 \text{ kg/kmol}) = 1120 \text{ kg} \\ m_{\text{CO}_2} &= N_{\text{CO}_2} M_{\text{CO}_2} = (10 \text{ kmol})(44 \text{ kg/kmol}) = 440 \text{ kg} \\ m_{\text{CH}_4} &= N_{\text{CH}_4} M_{\text{CH}_4} = (20 \text{ kmol})(16 \text{ kg/kmol}) = 320 \text{ kg} \end{aligned}$$

The total mass is

$$\begin{aligned} m_m &= m_{\text{O}_2} + m_{\text{N}_2} + m_{\text{CO}_2} + m_{\text{CH}_4} \\ &= 960 + 1120 + 440 + 320 \\ &= 2840 \text{ kg} \end{aligned}$$

Then the mass fractions are

$$\begin{aligned} \text{mf}_{\text{O}_2} &= \frac{m_{\text{O}_2}}{m_m} = \frac{960 \text{ kg}}{2840 \text{ kg}} = 0.3380 \\ \text{mf}_{\text{N}_2} &= \frac{m_{\text{N}_2}}{m_m} = \frac{1120 \text{ kg}}{2840 \text{ kg}} = 0.3944 \\ \text{mf}_{\text{CO}_2} &= \frac{m_{\text{CO}_2}}{m_m} = \frac{440 \text{ kg}}{2840 \text{ kg}} = 0.1549 \\ \text{mf}_{\text{CH}_4} &= \frac{m_{\text{CH}_4}}{m_m} = \frac{320 \text{ kg}}{2840 \text{ kg}} = 0.1127 \end{aligned}$$

The constant-pressure specific heat of the mixture is determined from

$$\begin{aligned} c_p &= \text{mf}_{\text{O}_2} c_{p,\text{O}_2} + \text{mf}_{\text{N}_2} c_{p,\text{N}_2} + \text{mf}_{\text{CO}_2} c_{p,\text{CO}_2} + \text{mf}_{\text{CH}_4} c_{p,\text{CH}_4} \\ &= 0.3380 \times 0.918 + 0.3944 \times 1.039 + 0.1549 \times 0.846 + 0.1127 \times 2.2537 \\ &= 1.1051 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

An energy balance on the tube gives

$$q_{\text{in}} = c_p (T_2 - T_1) = (1.1051 \text{ kJ/kg} \cdot \text{K})(200 - 20) \text{ K} = \mathbf{199 \text{ kJ/kg}}$$

13-51 Oxygen, nitrogen, and argon gases are supplied from separate tanks at different temperatures to form a mixture. The total entropy change for the mixing process is to be determined.

Assumptions Under specified conditions all N_2 , O_2 , and argon can be treated as ideal gases, and the mixture as an ideal gas mixture.

Properties The molar masses of O_2 , N_2 , and Ar are 32.0, 28.0, and 40.0 kg/kmol, respectively (Table A-1). The properties of Argon are $R = 0.2081$ kJ/kg.K and $c_p = 0.5203$ kJ/kg.K (Table A-2).

Analysis Note that volume fractions are equal to mole fractions in ideal gas mixtures. The partial pressures in the mixture are

$$P_{O_2,2} = y_{O_2} P_m = (0.21)(200 \text{ kPa}) = 42 \text{ kPa}$$

$$P_{N_2,2} = y_{N_2} P_m = (0.78)(200 \text{ kPa}) = 156 \text{ kPa}$$

$$P_{Ar,2} = y_{Ar} P_m = (0.01)(200 \text{ kPa}) = 2 \text{ kPa}$$

The molar mass of the mixture is determined to be

$$\begin{aligned} M_m &= y_{O_2} M_{O_2} + y_{N_2} M_{N_2} + y_{Ar} M_{Ar} \\ &= (0.21)(32 \text{ kg/kmol}) + (0.78)(28) + (0.01)(40) = 28.96 \text{ kg/kmol} \end{aligned}$$

The mass fractions are

$$mf_{O_2} = y_{O_2} \frac{M_{O_2}}{M_m} = (0.21) \frac{32 \text{ kg/kmol}}{28.96 \text{ kg/kmol}} = 0.2320$$

$$mf_{N_2} = y_{N_2} \frac{M_{N_2}}{M_m} = (0.78) \frac{28 \text{ kg/kmol}}{28.96 \text{ kg/kmol}} = 0.7541$$

$$mf_{Ar} = y_{Ar} \frac{M_{Ar}}{M_m} = (0.01) \frac{40 \text{ kg/kmol}}{28.96 \text{ kg/kmol}} = 0.0138$$

The final temperature of the mixture is needed. The conservation of energy on a unit mass basis for steady flow mixing with no heat transfer or work allows calculation of mixture temperature. All components of the exit mixture have the same common temperature, T_m . We obtain the properties of O_2 and N_2 from EES:

$$\begin{aligned} e_{in} &= e_{out} \\ mf_{O_2} h_{@10^\circ\text{C}} + mf_{N_2} h_{@60^\circ\text{C}} + mf_{Ar} c_{p,Ar} T_{Ar,1} &= mf_{O_2} h_{@T_m} + mf_{N_2} h_{@T_m} + mf_{Ar} c_{p,Ar} T_m \\ (0.2320)(-13.85) + (0.7541)(36.47) + (0.0138)(0.5203)(200) &= (0.2320)h_{@T_m} + (0.7541)h_{@T_m} \\ &\quad + (0.0138)(0.5203)T_m \end{aligned}$$

Solving this equation in EES we find $T_m = 50.4^\circ\text{C}$. The entropies of O_2 and N_2 are obtained from EES to be

$$T = 10^\circ\text{C}, P = 200 \text{ kPa} \longrightarrow s_{O_2,1} = 6.1797 \text{ kJ/kg.K}$$

$$T = 50.4^\circ\text{C}, P = 42 \text{ kPa} \longrightarrow s_{O_2,2} = 6.7082 \text{ kJ/kg.K}$$

$$T = 60^\circ\text{C}, P = 200 \text{ kPa} \longrightarrow s_{N_2,1} = 6.7461 \text{ kJ/kg.K}$$

$$T = 50.4^\circ\text{C}, P = 156 \text{ kPa} \longrightarrow s_{N_2,2} = 6.7893 \text{ kJ/kg.K}$$

The entropy changes are

$$\Delta s_{O_2} = s_{O_2,2} - s_{O_2,1} = 6.7082 - 6.1797 = 0.5284 \text{ kJ/kg.K}$$

$$\Delta s_{N_2} = s_{N_2,2} - s_{N_2,1} = 6.7893 - 6.7461 = 0.04321 \text{ kJ/kg.K}$$

$$\Delta s_{Ar} = c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} = (0.5203) \ln \left(\frac{50.4 + 273}{200 + 273} \right) - (0.2081) \ln \left(\frac{2}{200} \right) = 0.7605 \text{ kJ/kg.K}$$

The total entropy change is

$$\begin{aligned} \Delta s_{total} &= mf_{O_2} \Delta s_{O_2} + mf_{N_2} \Delta s_{N_2} + mf_{Ar} \Delta s_{Ar} \\ &= (0.2320)(0.5284) + (0.7541)(0.04321) + (0.0138)(0.7605) = \mathbf{0.1656 \text{ kJ/kg.K}} \end{aligned}$$

13-52E A mixture of helium and nitrogen is heated at constant pressure in a closed system. The work produced is to be determined.

Assumptions **1** Helium and nitrogen are ideal gases. **2** The process is reversible.

Properties The mole numbers of helium and nitrogen are 4.0 and 28.0 lbm/lbmol, respectively (Table A-1E).

Analysis One lbm of this mixture consists of 0.35 lbm of nitrogen and 0.65 lbm of helium or $0.35 \text{ lbm}/(28.0 \text{ lbm/lbmol}) = 0.0125 \text{ lbmol}$ of nitrogen and $0.65 \text{ lbm}/(4.0 \text{ lbm/lbmol}) = 0.1625 \text{ lbmol}$ of helium. The total mole is $0.0125 + 0.1625 = 0.175 \text{ lbmol}$. The constituent mole fraction are then

$$y_{\text{N}_2} = \frac{N_{\text{N}_2}}{N_{\text{total}}} = \frac{0.0125 \text{ lbmol}}{0.175 \text{ lbmol}} = 0.07143$$

$$y_{\text{He}} = \frac{N_{\text{He}}}{N_{\text{total}}} = \frac{0.1625 \text{ lbmol}}{0.175 \text{ lbmol}} = 0.9286$$

The effective molecular weight of this mixture is

$$\begin{aligned} M &= y_{\text{N}_2} M_{\text{N}_2} + y_{\text{He}} M_{\text{He}} \\ &= (0.07143)(28) + (0.9286)(4) \\ &= 5.714 \text{ lbm/lbmol} \end{aligned}$$

The work done is determined from

$$\begin{aligned} w &= \int_1^2 P d\mathbf{v} = P_2 \mathbf{v}_2 - P_1 \mathbf{v}_1 = R(T_2 - T_1) \\ &= \frac{R_u}{M} (T_2 - T_1) = \frac{1.9858 \text{ Btu/lbmol} \cdot \text{R}}{5.714 \text{ lbm/lbmol}} (500 - 100) \text{R} \\ &= \mathbf{139.0 \text{ Btu/lbm}} \end{aligned}$$

13-53 The volumetric fractions of the constituents of a mixture are given. The makeup of the mixture on a mass basis and the enthalpy change per unit mass of mixture during a process are to be determined.

Assumptions Under specified conditions all N_2 , O_2 , and CO_2 can be treated as ideal gases, and the mixture as an ideal gas mixture.

Properties The molar masses of CO_2 , O_2 , and N_2 are 44.0, 32.0, and 28.0 kg/kmol, respectively (Table A-1).

Analysis Noting that volume fractions are equal to mole fractions in ideal gas mixtures, the molar mass of the mixture is determined to be

$$M_m = y_{CO_2} M_{CO_2} + y_{O_2} M_{O_2} + y_{N_2} M_{N_2} = (0.20)(44 \text{ kg/kmol}) + (0.10)(32) + (0.70)(28) = 31.60 \text{ kg/kmol}$$

The mass fractions are

$$mf_{CO_2} = y_{CO_2} \frac{M_{CO_2}}{M_m} = (0.20) \frac{44 \text{ kg/kmol}}{31.60 \text{ kg/kmol}} = \mathbf{0.2785}$$

$$mf_{O_2} = y_{O_2} \frac{M_{O_2}}{M_m} = (0.10) \frac{32 \text{ kg/kmol}}{31.60 \text{ kg/kmol}} = \mathbf{0.1013}$$

$$mf_{N_2} = y_{N_2} \frac{M_{N_2}}{M_m} = (0.70) \frac{28 \text{ kg/kmol}}{31.60 \text{ kg/kmol}} = \mathbf{0.6203}$$

70% N_2 10% O_2 20% CO_2

$T_1 = 300 \text{ K}$ $T_2 = 500 \text{ K}$
--

The enthalpy change of each gas and the enthalpy change of the mixture are (from Tables A-18-20)

$$\Delta h_{CO_2} = \frac{\bar{h}_{@500\text{K}} - \bar{h}_{@300\text{K}}}{M_{CO_2}} = \frac{(17,678 - 9431) \text{ kJ/kmol}}{44 \text{ kg/kmol}} = 187.43 \text{ kJ/kg}$$

$$\Delta h_{O_2} = \frac{\bar{h}_{@500\text{K}} - \bar{h}_{@300\text{K}}}{M_{O_2}} = \frac{(14,770 - 8736) \text{ kJ/kmol}}{32 \text{ kg/kmol}} = 188.56 \text{ kJ/kg}$$

$$\Delta h_{N_2} = \frac{\bar{h}_{@500\text{K}} - \bar{h}_{@300\text{K}}}{M_{N_2}} = \frac{(14,581 - 8723) \text{ kJ/kmol}}{28 \text{ kg/kmol}} = 209.21 \text{ kJ/kg}$$

$$\begin{aligned} \Delta h_m &= mf_{CO_2} \Delta h_{CO_2} + mf_{O_2} \Delta h_{O_2} + mf_{N_2} \Delta h_{N_2} \\ &= (0.2785)(187.43) + (0.1013)(188.56) + (0.6203)(209.21) \\ &= \mathbf{201.1 \text{ kJ/kg}} \end{aligned}$$

13-54 The temperatures and pressures of two gases forming a mixture are given. The final mixture temperature and pressure are to be determined.

Assumptions 1 Under specified conditions both Ne and Ar can be treated as ideal gases, and the mixture as an ideal gas mixture. **2** There are no other forms of work involved.

Properties The molar masses and specific heats of Ne and Ar are 20.18 kg/kmol, 39.95 kg/kmol, 0.6179 kJ/kg·°C, and 0.3122 kJ/kg·°C, respectively. (Tables A-1 and A-2).

Analysis The mole number of each gas is

$$N_{\text{Ne}} = \left(\frac{P_1 V_1}{R_u T_1} \right)_{\text{Ne}} = \frac{(100 \text{ kPa})(0.45 \text{ m}^3)}{(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(293 \text{ K})} = 0.0185 \text{ kmol}$$

$$N_{\text{Ar}} = \left(\frac{P_1 V_1}{R_u T_1} \right)_{\text{Ar}} = \frac{(200 \text{ kPa})(0.45 \text{ m}^3)}{(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(323 \text{ K})} = 0.0335 \text{ kmol}$$

Thus,

$$N_m = N_{\text{Ne}} + N_{\text{Ar}} = 0.0185 \text{ kmol} + 0.0335 \text{ kmol} = 0.0520 \text{ kmol}$$

(a) We take both gases as the system. No work or mass crosses the system boundary, therefore this is a closed system with $W = 0$. Then the conservation of energy equation for this closed system reduces to

$$E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$$

$$-Q_{\text{out}} = \Delta U = \Delta U_{\text{Ne}} + \Delta U_{\text{Ar}} \longrightarrow -Q_{\text{out}} = [mc_v(T_m - T_1)]_{\text{Ne}} + [mc_v(T_m - T_1)]_{\text{Ar}}$$

Using c_v values at room temperature and noting that $m = NM$, the final temperature of the mixture is determined to be

$$-15 \text{ kJ} = (0.0185 \times 20.18 \text{ kg})(0.6179 \text{ kJ/kg} \cdot \text{°C})(T_m - 20\text{°C})$$

$$+ (0.0335 \times 39.95 \text{ kg})(0.3122 \text{ kJ/kg} \cdot \text{°C})(T_m - 50\text{°C})$$

$$T_m = \mathbf{16.2\text{°C}} \quad (289.2 \text{ K})$$

(b) The final pressure in the tank is determined from

$$P_m = \frac{N_m R_u T_m}{V_m} = \frac{(0.052 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(289.2 \text{ K})}{0.9 \text{ m}^3} = \mathbf{138.9 \text{ kPa}}$$

13-55 The temperatures and pressures of two gases forming a mixture are given. The final mixture temperature and pressure are to be determined.

Assumptions 1 Under specified conditions both Ne and Ar can be treated as ideal gases, and the mixture as an ideal gas mixture. **2** There are no other forms of work involved.

Properties The molar masses and specific heats of Ne and Ar are 20.18 kg/kmol, 39.95 kg/kmol, 0.6179 kJ/kg·°C, and 0.3122 kJ/kg·°C, respectively. (Tables A-1 and A-2b).

Analysis The mole number of each gas is

$$N_{\text{Ne}} = \left(\frac{P_1 V_1}{R_u T_1} \right)_{\text{Ne}} = \frac{(100 \text{ kPa})(0.45 \text{ m}^3)}{(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(293 \text{ K})} = 0.0185 \text{ kmol}$$

$$N_{\text{Ar}} = \left(\frac{P_1 V_1}{R_u T_1} \right)_{\text{Ar}} = \frac{(200 \text{ kPa})(0.45 \text{ m}^3)}{(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(323 \text{ K})} = 0.0335 \text{ kmol}$$

Thus,

$$N_m = N_{\text{Ne}} + N_{\text{Ar}} = 0.0185 \text{ kmol} + 0.0335 \text{ kmol} = 0.0520 \text{ kmol}$$

(a) We take both gases as the system. No work or mass crosses the system boundary, therefore this is a closed system with $W = 0$. Then the conservation of energy equation for this closed system reduces to

$$E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$$

$$-Q_{\text{out}} = \Delta U = \Delta U_{\text{Ne}} + \Delta U_{\text{Ar}}$$

$$-Q_{\text{out}} = [mc_v(T_m - T_1)]_{\text{Ne}} + [mc_v(T_m - T_1)]_{\text{Ar}}$$

Using c_v values at room temperature and noting that $m = NM$, the final temperature of the mixture is determined to be

$$-8 \text{ kJ} = (0.0185 \times 20.18 \text{ kg})(0.6179 \text{ kJ/kg} \cdot \text{°C})(T_m - 20\text{°C})$$

$$+ (0.0335 \times 39.95 \text{ kg})(0.3122 \text{ kJ/kg} \cdot \text{°C})(T_m - 50\text{°C})$$

$$T_m = \mathbf{27.0\text{°C}} \quad (300.0 \text{ K})$$

(b) The final pressure in the tank is determined from

$$P_m = \frac{N_m R_u T_m}{V_m} = \frac{(0.052 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(300.0 \text{ K})}{0.9 \text{ m}^3} = \mathbf{144.1 \text{ kPa}}$$

13-56 The mass fractions of components of a gas mixture are given. This mixture is enclosed in a rigid, well-insulated vessel, and a paddle wheel in the vessel is turned until specified amount of work have been done on the mixture. The mixture's final pressure and temperature are to be determined.

Assumptions All gases will be modeled as ideal gases with constant specific heats.

Properties The molar masses of N_2 , He, CH_4 , and C_2H_6 are 28.0, 4.0, 16.0, and 30.0 kg/kmol, respectively (Table A-1). The constant-pressure specific heats of these gases at room temperature are 1.039, 5.1926, 2.2537, and 1.7662 kJ/kg·K, respectively (Table A-2a).

Analysis We consider 100 kg of this mixture. The mole numbers of each component are

$$N_{N_2} = \frac{m_{N_2}}{M_{N_2}} = \frac{15 \text{ kg}}{28 \text{ kg/kmol}} = 0.5357 \text{ kmol}$$

$$N_{He} = \frac{m_{He}}{M_{He}} = \frac{5 \text{ kg}}{4 \text{ kg/kmol}} = 1.25 \text{ kmol}$$

$$N_{CH_4} = \frac{m_{CH_4}}{M_{CH_4}} = \frac{60 \text{ kg}}{16 \text{ kg/kmol}} = 3.75 \text{ kmol}$$

$$N_{C_2H_6} = \frac{m_{C_2H_6}}{M_{C_2H_6}} = \frac{20 \text{ kg}}{30 \text{ kg/kmol}} = 0.6667 \text{ kmol}$$

The mole number of the mixture is

$$N_m = N_{N_2} + N_{He} + N_{CH_4} + N_{C_2H_6} = 0.5357 + 1.25 + 3.75 + 0.6667 = 6.2024 \text{ kmol}$$

The apparent molecular weight of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{100 \text{ kg}}{6.2024 \text{ kmol}} = 16.12 \text{ kg/kmol}$$

The constant-pressure specific heat of the mixture is determined from

$$c_p = mf_{N_2}c_{p,N_2} + mf_{He}c_{p,He} + mf_{CH_4}c_{p,CH_4} + mf_{C_2H_6}c_{p,C_2H_6}$$

$$= 0.15 \times 1.039 + 0.05 \times 5.1926 + 0.60 \times 2.2537 + 0.20 \times 1.7662$$

$$= 2.121 \text{ kJ/kg} \cdot \text{K}$$

The apparent gas constant of the mixture is

$$R = \frac{R_u}{M_m} = \frac{8.134 \text{ kJ/kmol} \cdot \text{K}}{16.12 \text{ kg/kmol}} = 0.5158 \text{ kJ/kg} \cdot \text{K}$$

Then the constant-volume specific heat is

$$c_v = c_p - R = 2.121 - 0.5158 = 1.605 \text{ kJ/kg} \cdot \text{K}$$

The mass in the container is

$$m_m = \frac{P_1 V_m}{RT_1} = \frac{(150 \text{ kPa})(4 \text{ m}^3)}{(0.5158 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(303 \text{ K})} = 3.840 \text{ kg}$$

An energy balance on the system gives

$$W_{sh,in} = m_m c_v (T_2 - T_1) \longrightarrow T_2 = T_1 + \frac{W_{sh,in}}{m_m c_v} = (303 \text{ K}) + \frac{200 \text{ kJ}}{(3.840 \text{ kg})(1.605 \text{ kJ/kg} \cdot \text{K})} = \mathbf{335.4 \text{ K}}$$

Since the volume remains constant and this is an ideal gas,

$$P_2 = P_1 \frac{T_2}{T_1} = (150 \text{ kPa}) \frac{335.4 \text{ K}}{303 \text{ K}} = \mathbf{166.1 \text{ kPa}}$$

13-57 The states of two gases contained in two tanks are given. The gases are allowed to mix to form a homogeneous mixture. The final pressure, the heat transfer, and the entropy generated are to be determined.

Assumptions 1 Under specified conditions both O_2 and N_2 can be treated as ideal gases, and the mixture as an ideal gas mixture. **2** The tank containing oxygen is insulated. **3** There are no other forms of work involved.

Properties The constant volume specific heats of O_2 and N_2 are $0.658 \text{ kJ/kg}\cdot^\circ\text{C}$ and $0.743 \text{ kJ/kg}\cdot^\circ\text{C}$, respectively. (Table A-2).

Analysis (a) The volume of the O_2 tank and mass of the nitrogen are

$$V_{1,O_2} = \left(\frac{mRT_1}{P_1} \right)_{O_2} = \frac{(1 \text{ kg})(0.2598 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(288 \text{ K})}{300 \text{ kPa}} = 0.25 \text{ m}^3$$

$$m_{N_2} = \left(\frac{P_1 V_1}{RT_1} \right)_{N_2} = \frac{(500 \text{ kPa})(2 \text{ m}^3)}{(0.2968 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(323 \text{ K})} = 10.43 \text{ kg}$$

$$V_{\text{total}} = V_{1,O_2} + V_{1,N_2} = 0.25 \text{ m}^3 + 2.0 \text{ m}^3 = 2.25 \text{ m}^3$$

Also,

$$m_{O_2} = 1 \text{ kg} \longrightarrow N_{O_2} = \frac{m_{O_2}}{M_{O_2}} = \frac{1 \text{ kg}}{32 \text{ kg/kmol}} = 0.03125 \text{ kmol}$$

$$m_{N_2} = 10.43 \text{ kg} \longrightarrow N_{N_2} = \frac{m_{N_2}}{M_{N_2}} = \frac{10.43 \text{ kg}}{28 \text{ kg/kmol}} = 0.3725 \text{ kmol}$$

$$N_m = N_{N_2} + N_{O_2} = 0.3725 \text{ kmol} + 0.03125 \text{ kmol} = 0.40375 \text{ kmol}$$

Thus,

$$P_m = \left(\frac{NR_u T}{V} \right)_m = \frac{(0.40375 \text{ kmol})(8.314 \text{ kPa}\cdot\text{m}^3/\text{kmol}\cdot\text{K})(298 \text{ K})}{2.25 \text{ m}^3} = \mathbf{444.6 \text{ kPa}}$$

(b) We take both gases as the system. No work or mass crosses the system boundary, and thus this is a closed system with $W = 0$. Taking the direction of heat transfer to be from the system (will be verified), the energy balance for this closed system reduces to

$$E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$$

$$-Q_{\text{out}} = \Delta U = \Delta U_{O_2} + \Delta U_{N_2} \longrightarrow Q_{\text{out}} = [mc_v(T_1 - T_m)]_{O_2} + [mc_v(T_1 - T_m)]_{N_2}$$

Using c_v values at room temperature (Table A-2), the heat transfer is determined to be

$$Q_{\text{out}} = (1 \text{ kg})(0.658 \text{ kJ/kg}\cdot^\circ\text{C})(15 - 25)^\circ\text{C} + (10.43 \text{ kg})(0.743 \text{ kJ/kg}\cdot^\circ\text{C})(50 - 25)^\circ\text{C}$$

$$= \mathbf{187.2 \text{ kJ}} \quad (\text{from the system})$$

(c) For an *extended system* that involves the tanks and their immediate surroundings such that the boundary temperature is the surroundings temperature, the entropy balance can be expressed as

$$S_{\text{in}} - S_{\text{out}} + S_{\text{gen}} = \Delta S_{\text{system}}$$

$$-\frac{Q_{\text{out}}}{T_{b,\text{sur}}} + S_{\text{gen}} = m(s_2 - s_1)$$

$$S_{\text{gen}} = m(s_2 - s_1) + \frac{Q_{\text{out}}}{T_{\text{sur}}}$$

The mole fraction of each gas is

$$y_{\text{O}_2} = \frac{N_{\text{O}_2}}{N_m} = \frac{0.03125}{0.40375} = 0.077$$

$$y_{\text{N}_2} = \frac{N_{\text{N}_2}}{N_m} = \frac{0.3725}{0.40375} = 0.923$$

Thus,

$$\begin{aligned} (s_2 - s_1)_{\text{O}_2} &= \left(c_p \ln \frac{T_2}{T_1} - R \ln \frac{y P_{m,2}}{P_1} \right)_{\text{O}_2} \\ &= (0.918 \text{ kJ/kg} \cdot \text{K}) \ln \frac{298 \text{ K}}{288 \text{ K}} - (0.2598 \text{ kJ/kg} \cdot \text{K}) \ln \frac{(0.077)(444.6 \text{ kPa})}{300 \text{ kPa}} \\ &= 0.5952 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

$$\begin{aligned} (s_2 - s_1)_{\text{N}_2} &= \left(c_p \ln \frac{T_2}{T_1} - R \ln \frac{y P_{m,2}}{P_1} \right)_{\text{N}_2} \\ &= (1.039 \text{ kJ/kg} \cdot \text{K}) \ln \frac{298 \text{ K}}{323 \text{ K}} - (0.2968 \text{ kJ/kg} \cdot \text{K}) \ln \frac{(0.923)(444.6 \text{ kPa})}{500 \text{ kPa}} \\ &= -0.0251 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

Substituting,

$$S_{\text{gen}} = (1 \text{ kg})(0.5952 \text{ kJ/kg} \cdot \text{K}) + (10.43 \text{ kg})(-0.0251 \text{ kJ/kg} \cdot \text{K}) + \frac{187.2 \text{ kJ}}{298 \text{ K}} = \mathbf{0.962 \text{ kJ/K}}$$

13-58 Problem 13-57 is reconsidered. The results obtained assuming ideal gas behavior with constant specific heats at the average temperature, and using real gas data obtained from EES by assuming variable specific heats over the temperature range are to be compared.

Analysis The problem is solved using EES, and the solution is given below.

13-59 The mass fractions of components of a gas mixture are given. This mixture is compressed in a reversible, isothermal, steady-flow compressor. The work and heat transfer for this compression per unit mass of the mixture are to be determined.

Assumptions All gases will be modeled as ideal gases with constant specific heats.

Properties The molar masses of CH_4 , C_3H_8 , and C_4H_{10} are 16.0, 44.0, and 58.0 kg/kmol, respectively (Table A-1).

Analysis The mole numbers of each component are

$$N_{\text{CH}_4} = \frac{m_{\text{CH}_4}}{M_{\text{CH}_4}} = \frac{60 \text{ kg}}{16 \text{ kg/kmol}} = 3.75 \text{ kmol}$$

$$N_{\text{C}_3\text{H}_8} = \frac{m_{\text{C}_3\text{H}_8}}{M_{\text{C}_3\text{H}_8}} = \frac{25 \text{ kg}}{44 \text{ kg/kmol}} = 0.5682 \text{ kmol}$$

$$N_{\text{C}_4\text{H}_{10}} = \frac{m_{\text{C}_4\text{H}_{10}}}{M_{\text{C}_4\text{H}_{10}}} = \frac{15 \text{ kg}}{58 \text{ kg/kmol}} = 0.2586 \text{ kmol}$$

The mole number of the mixture is

$$N_m = N_{\text{CH}_4} + N_{\text{C}_3\text{H}_8} + N_{\text{C}_4\text{H}_{10}}$$

$$= 3.75 + 0.5682 + 0.2586 = 4.5768 \text{ kmol}$$

The apparent molecular weight of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{100 \text{ kg}}{4.5768 \text{ kmol}} = 21.85 \text{ kg/kmol}$$

The apparent gas constant of the mixture is

$$R = \frac{R_u}{M_m} = \frac{8.314 \text{ kJ/kmol} \cdot \text{K}}{21.85 \text{ kg/kmol}} = 0.3805 \text{ kJ/kg} \cdot \text{K}$$

For a reversible, isothermal process, the work input is

$$w_{\text{in}} = RT \ln\left(\frac{P_2}{P_1}\right) = (0.3805 \text{ kJ/kg} \cdot \text{K})(293 \text{ K}) \ln\left(\frac{1000 \text{ kPa}}{100 \text{ kPa}}\right) = \mathbf{257 \text{ kJ/kg}}$$

An energy balance on the control volume gives

$$\underbrace{\dot{E}_{\text{in}} - \dot{E}_{\text{out}}}_{\text{Rate of net energy transfer by heat, work, and mass}} = \underbrace{\Delta \dot{E}_{\text{system}}}_{\text{Rate of change in internal, kinetic, potential, etc. energies}} \stackrel{\text{no (steady)}}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\dot{m}h_1 + \dot{W}_{\text{in}} = \dot{m}h_2 + \dot{Q}_{\text{out}}$$

$$\dot{W}_{\text{in}} - \dot{Q}_{\text{out}} = \dot{m}(h_2 - h_1)$$

$$w_{\text{in}} - q_{\text{out}} = c_p(T_2 - T_1) = 0 \quad \text{since } T_2 = T_1$$

$$w_{\text{in}} = q_{\text{out}}$$

That is,

$$q_{\text{out}} = w_{\text{in}} = \mathbf{257 \text{ kJ/kg}}$$

13-60 An equimolar mixture of helium and argon gases expands in a turbine. The isentropic work output of the turbine is to be determined.

Assumptions **1** Under specified conditions both He and Ar can be treated as ideal gases, and the mixture as an ideal gas mixture. **2** The turbine is insulated and thus there is no heat transfer. **3** This is a steady-flow process. **4** The kinetic and potential energy changes are negligible.

Properties The molar masses and specific heats of He and Ar are 4.0 kg/kmol, 40.0 kg/kmol, 5.1926 kJ/kg·°C, and 0.5203 kJ/kg·°C, respectively. (Table A-1 and Table A-2).

Analysis The C_p and k values of this equimolar mixture are determined from

$$M_m = \sum y_i M_i = y_{\text{He}} M_{\text{He}} + y_{\text{Ar}} M_{\text{Ar}} = 0.5 \times 4 + 0.5 \times 40 = 22 \text{ kg/kmol}$$

$$\text{mf}_i = \frac{m_i}{m_m} = \frac{N_i M_i}{N_m M_m} = \frac{y_i M_i}{M_m}$$

$$\begin{aligned} c_{p,m} &= \sum \text{mf}_i c_{p,i} = \frac{y_{\text{He}} M_{\text{He}}}{M_m} c_{p,\text{He}} + \frac{y_{\text{Ar}} M_{\text{Ar}}}{M_m} c_{p,\text{Ar}} \\ &= \frac{0.5 \times 4 \text{ kg/kmol}}{22 \text{ kg/kmol}} (5.1926 \text{ kJ/kg} \cdot \text{K}) + \frac{0.5 \times 40 \text{ kg/kmol}}{22 \text{ kg/kmol}} (0.5203 \text{ kJ/kg} \cdot \text{K}) \\ &= 0.945 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

and

$$k_m = 1.667 \quad \text{since } k = 1.667 \text{ for both gases.}$$

Therefore, the He-Ar mixture can be treated as a single ideal gas with the properties above. For isentropic processes,

$$T_2 = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (1300 \text{ K}) \left(\frac{200 \text{ kPa}}{2500 \text{ kPa}} \right)^{0.667/1.667} = 473.2 \text{ K}$$

From an energy balance on the turbine,

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \stackrel{\phi=0(\text{steady})}{=} 0 \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ h_1 &= h_2 + w_{\text{out}} \\ w_{\text{out}} &= h_1 - h_2 \\ w_{\text{out}} &= c_p (T_1 - T_2) = (0.945 \text{ kJ/kg} \cdot \text{K})(1300 - 473.2) \text{ K} = \mathbf{781.3 \text{ kJ/kg}} \end{aligned}$$

13-61E The volume fractions of components of a gas mixture passing through the turbine of a simple ideal Brayton cycle are given. The thermal efficiency of this cycle is to be determined.

Assumptions All gases will be modeled as ideal gases with constant specific heats.

Properties The molar masses of N_2 , O_2 , H_2O , and CO_2 are 28.0, 32.0, 18.0, and 44.0 lbm/lbmol, respectively (Table A-1E). The constant-pressure specific heats of these gases at room temperature are 0.248, 0.219, 0.445, and 0.203 Btu/lbm·R, respectively. The air properties at room temperature are $c_p = 0.240$ Btu/lbm·R, $c_v = 0.171$ Btu/lbm·R, $k = 1.4$ (Table A-2Ea).

Analysis We consider 100 lbmol of this mixture. Noting that volume fractions are equal to the mole fractions, mass of each component are

$$\begin{aligned} m_{N_2} &= N_{N_2} M_{N_2} = (20 \text{ lbmol})(28 \text{ lbm/lbmol}) = 560 \text{ lbm} \\ m_{O_2} &= N_{O_2} M_{O_2} = (5 \text{ lbmol})(32 \text{ lbm/lbmol}) = 160 \text{ lbm} \\ m_{H_2O} &= N_{H_2O} M_{H_2O} = (35 \text{ lbmol})(18 \text{ lbm/lbmol}) = 630 \text{ lbm} \\ m_{CO_2} &= N_{CO_2} M_{CO_2} = (40 \text{ lbmol})(44 \text{ lbm/lbmol}) = 1760 \text{ lbm} \end{aligned}$$

The total mass is

$$\begin{aligned} m_m &= m_{N_2} + m_{O_2} + m_{H_2O} + m_{CO_2} \\ &= 560 + 160 + 630 + 1760 \\ &= 3110 \text{ lbm} \end{aligned}$$

Then the mass fractions are

$$\begin{aligned} mf_{N_2} &= \frac{m_{N_2}}{m_m} = \frac{560 \text{ lbm}}{3110 \text{ lbm}} = 0.1801 \\ mf_{O_2} &= \frac{m_{O_2}}{m_m} = \frac{160 \text{ lbm}}{3110 \text{ lbm}} = 0.05145 \\ mf_{H_2O} &= \frac{m_{H_2O}}{m_m} = \frac{630 \text{ lbm}}{3110 \text{ lbm}} = 0.2026 \\ mf_{CO_2} &= \frac{m_{CO_2}}{m_m} = \frac{1760 \text{ lbm}}{3110 \text{ lbm}} = 0.5659 \end{aligned}$$

The constant-pressure specific heat of the mixture is determined from

$$\begin{aligned} c_p &= mf_{N_2} c_{p,N_2} + mf_{O_2} c_{p,O_2} + mf_{H_2O} c_{p,H_2O} + mf_{CO_2} c_{p,CO_2} \\ &= 0.1801 \times 0.248 + 0.05145 \times 0.219 + 0.2026 \times 0.445 + 0.5659 \times 0.203 \\ &= 0.2610 \text{ Btu/lbm} \cdot \text{R} \end{aligned}$$

The apparent molecular weight of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{3110 \text{ lbm}}{100 \text{ lbmol}} = 31.10 \text{ lbm/lbmol}$$

The apparent gas constant of the mixture is

$$R = \frac{R_u}{M_m} = \frac{1.9858 \text{ Btu/lbmol} \cdot \text{R}}{31.10 \text{ lbm/lbmol}} = 0.06385 \text{ Btu/lbm} \cdot \text{R}$$

Then the constant-volume specific heat is

$$c_v = c_p - R = 0.2610 - 0.06385 = 0.1971 \text{ Btu/lbm} \cdot \text{R}$$

The specific heat ratio is

$$k = \frac{c_p}{c_v} = \frac{0.2610}{0.1971} = 1.324$$

The average of the air properties at room temperature and combustion gas properties are

20% N_2 , 5% O_2
35% H_2O , 40% CO_2
(by volume)

$$c_{p,\text{avg}} = 0.5(0.2610 + 0.240) = 0.2505 \text{ Btu/lbm} \cdot \text{R}$$

$$c_{v,\text{avg}} = 0.5(0.1971 + 0.171) = 0.1841 \text{ Btu/lbm} \cdot \text{R}$$

$$k_{\text{avg}} = 0.5(1.324 + 1.4) = 1.362$$

These average properties will be used for heat addition and rejection processes. For compression, the air properties at room temperature and during expansion, the mixture properties will be used. During the compression process,

$$T_2 = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (500 \text{ R})(6)^{0.4/1.4} = 834.3 \text{ R}$$

During the heat addition process,

$$q_{\text{in}} = c_{p,\text{avg}}(T_3 - T_2) = (0.2505 \text{ Btu/lbm} \cdot \text{R})(1860 - 834.3) \text{ R} = 256.9 \text{ Btu/lbm}$$

During the expansion process,

$$T_4 = T_3 \left(\frac{P_4}{P_3} \right)^{(k-1)/k} = (1860 \text{ R}) \left(\frac{1}{6} \right)^{0.362/1.362} = 1155.3 \text{ R}$$

During the heat rejection process,

$$q_{\text{out}} = c_{p,\text{avg}}(T_4 - T_1) = (0.2505 \text{ Btu/lbm} \cdot \text{R})(1155.3 - 500) \text{ R} = 164.2 \text{ Btu/lbm}$$

The thermal efficiency of the cycle is then

$$\eta_{\text{th}} = 1 - \frac{q_{\text{out}}}{q_{\text{in}}} = 1 - \frac{164.2 \text{ Btu/lbm}}{256.9 \text{ Btu/lbm}} = 0.361 = \mathbf{36.1\%}$$

13-62E The thermal efficiency of the cycle in the previous problem is to be compared to that predicted by air standard analysis?

Assumptions Air-standard assumptions are applicable.

Properties The air properties at room temperature are $c_p = 0.240$ Btu/lbm·R, $c_v = 0.171$ Btu/lbm·R, $k = 1.4$ (Table A-2Ea).

Analysis In the previous problem, the thermal efficiency of the cycle was determined to be **0.361** (36.1%). The thermal efficiency with air-standard model is determined from

$$\eta_{\text{th}} = 1 - \frac{1}{r_p^{(k-1)/k}} = 1 - \frac{1}{6^{0.4/1.4}} = 0.401 = \mathbf{40.1\%}$$

which is greater than that calculated with gas mixture analysis in the previous problem.

13-63E The mass fractions of a natural gas mixture at a specified pressure and temperature trapped in a geological location are given. This natural gas is pumped to the surface. The work required is to be determined using Kay's rule and the enthalpy-departure method.

Properties The molar masses of CH_4 and C_2H_6 are 16.0 and 30.0 lbm/lbmol, respectively. The critical properties are 343.9 R, 673 psia for CH_4 and 549.8 R and 708 psia for C_2H_6 (Table A-1E). The constant-pressure specific heats of these gases at room temperature are 0.532 and 0.427 Btu/lbm·R, respectively (Table A-2Ea).

Analysis We consider 100 lbm of this mixture. Then the mole numbers of each component are

$$N_{\text{CH}_4} = \frac{m_{\text{CH}_4}}{M_{\text{CH}_4}} = \frac{75 \text{ lbm}}{16 \text{ lbm/lbmol}} = 4.6875 \text{ lbmol}$$

$$N_{\text{C}_2\text{H}_6} = \frac{m_{\text{C}_2\text{H}_6}}{M_{\text{C}_2\text{H}_6}} = \frac{25 \text{ lbm}}{30 \text{ lbm/lbmol}} = 0.8333 \text{ lbmol}$$

The mole number of the mixture and the mole fractions are

$$N_m = 4.6875 + 0.8333 = 5.5208 \text{ lbmol}$$

$$y_{\text{CH}_4} = \frac{N_{\text{CH}_4}}{N_m} = \frac{4.6875 \text{ lbmol}}{5.5208 \text{ lbmol}} = 0.8491$$

$$y_{\text{C}_2\text{H}_6} = \frac{N_{\text{C}_2\text{H}_6}}{N_m} = \frac{0.8333 \text{ lbmol}}{5.5208 \text{ lbmol}} = 0.1509$$

<p>75% CH_4 25% C_2H_6 (by mass) 1300 psia 300°F</p>

Then the apparent molecular weight of the mixture becomes

$$M_m = \frac{m_m}{N_m} = \frac{100 \text{ lbm}}{5.5208 \text{ lbmol}} = 18.11 \text{ lbm/lbmol}$$

The apparent gas constant of the mixture is

$$R = \frac{R_u}{M_m} = \frac{1.9858 \text{ Btu/lbmol} \cdot \text{R}}{18.11 \text{ lbm/lbmol}} = 0.1097 \text{ Btu/lbm} \cdot \text{R}$$

The constant-pressure specific heat of the mixture is determined from

$$c_p = \text{mf}_{\text{CH}_4} c_{p,\text{CH}_4} + \text{mf}_{\text{C}_2\text{H}_6} c_{p,\text{C}_2\text{H}_6} = 0.75 \times 0.532 + 0.25 \times 0.427 = 0.506 \text{ Btu/lbm} \cdot \text{R}$$

To use Kay's rule, we need to determine the pseudo-critical temperature and pseudo-critical pressure of the mixture using the critical point properties of gases.

$$\begin{aligned} T'_{\text{cr},m} &= \sum y_i T_{\text{cr},i} = y_{\text{CH}_4} T_{\text{cr},\text{CH}_4} + y_{\text{C}_2\text{H}_6} T_{\text{cr},\text{C}_2\text{H}_6} \\ &= (0.8491)(343.9 \text{ R}) + (0.1509)(549.8 \text{ R}) \\ &= 375.0 \text{ R} \end{aligned}$$

$$\begin{aligned} P'_{\text{cr},m} &= \sum y_i P_{\text{cr},i} = y_{\text{CH}_4} P_{\text{cr},\text{CH}_4} + y_{\text{C}_2\text{H}_6} P_{\text{cr},\text{C}_2\text{H}_6} \\ &= (0.8491)(673 \text{ psia}) + (0.1509)(708 \text{ psia}) \\ &= 678.3 \text{ psia} \end{aligned}$$

The compressibility factor of the gas mixture in the reservoir and the mass of this gas are

$$\left. \begin{aligned} T_R &= \frac{T_m}{T'_{\text{cr},m}} = \frac{760 \text{ R}}{375.0 \text{ R}} = 2.027 \\ P_R &= \frac{P_m}{P'_{\text{cr},m}} = \frac{1300 \text{ psia}}{678.3 \text{ psia}} = 1.917 \end{aligned} \right\} Z_m = 0.963 \quad (\text{Fig. A-15 or EES, we used EES.})$$

$$m = \frac{P\mathcal{V}}{Z_m RT} = \frac{(1300 \text{ psia})(2 \times 10^6 \text{ ft}^3)}{(0.963)(0.5925 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(760 \text{ R})} = 5.996 \times 10^6 \text{ lbm}$$

The enthalpy departure factors in the reservoir and the surface are (from EES or Fig. A-29, we used EES.)

$$\left. \begin{aligned} T_{R1} &= \frac{T_m}{T_{cr,m}} = \frac{760 \text{ R}}{375.0 \text{ R}} = 2.027 \\ P_{R1} &= \frac{P_m}{P_{cr,m}} = \frac{1300 \text{ psia}}{678.3 \text{ psia}} = 1.917 \end{aligned} \right\} Z_{h1} = 0.487$$

$$\left. \begin{aligned} T_{R2} &= \frac{T_m}{T_{cr,m}} = \frac{660 \text{ R}}{375.0 \text{ R}} = 1.76 \\ P_{R2} &= \frac{P_m}{P_{cr,m}} = \frac{20 \text{ psia}}{678.3 \text{ psia}} = 0.0295 \end{aligned} \right\} Z_{h2} = 0.0112$$

The enthalpy change for the ideal gas mixture is

$$(h_1 - h_2)_{\text{ideal}} = c_p(T_1 - T_2) = (0.506 \text{ Btu/lbm} \cdot \text{R})(760 - 660)\text{R} = 50.6 \text{ Btu/lbm}$$

The enthalpy change with departure factors is

$$\begin{aligned} h_1 - h_2 &= (h_1 - h_2)_{\text{ideal}} - RT'_{cr,m}(Z_{h1} - Z_{h2}) \\ &= 50.6 - (0.1096)(375)(0.487 - 0.0112) \\ &= 31.02 \text{ Btu/lbm} \end{aligned}$$

The work input is then

$$W_{\text{in}} = m(h_1 - h_2) = (5.996 \times 10^6 \text{ lbm})(31.02 \text{ Btu/lbm}) = \mathbf{1.86 \times 10^8 \text{ Btu}}$$

13-64E  A gas mixture with known mass fractions is accelerated through a nozzle from a specified state to a specified pressure. For a specified isentropic efficiency, the exit temperature and the exit velocity of the mixture are to be determined.

Assumptions 1 Under specified conditions both N_2 and CO_2 can be treated as ideal gases, and the mixture as an ideal gas mixture. **2** The nozzle is adiabatic and thus heat transfer is negligible. **3** This is a steady-flow process. **4** Potential energy changes are negligible.

Properties The specific heats of N_2 and CO_2 are $c_{p,N_2} = 0.248$ Btu/lbm·R, $c_{v,N_2} = 0.177$ Btu/lbm·R, $c_{p,CO_2} = 0.203$ Btu/lbm·R, and $c_{v,CO_2} = 0.158$ Btu/lbm·R. (Table A-2E).

Analysis (a) Under specified conditions both N_2 and CO_2 can be treated as ideal gases, and the mixture as an ideal gas mixture. The c_p , c_v , and k values of this mixture are determined from

$$\begin{aligned} c_{p,m} &= \sum mf_i c_{p,i} = mf_{N_2} c_{p,N_2} + mf_{CO_2} c_{p,CO_2} \\ &= (0.65)(0.248) + (0.35)(0.203) \\ &= 0.2323 \text{ Btu/lbm}\cdot\text{R} \end{aligned}$$

$$\begin{aligned} c_{v,m} &= \sum mf_i c_{v,i} = mf_{N_2} c_{v,N_2} + mf_{CO_2} c_{v,CO_2} \\ &= (0.65)(0.177) + (0.35)(0.158) \\ &= 0.1704 \text{ Btu/lbm}\cdot\text{R} \end{aligned}$$

$$k_m = \frac{c_{p,m}}{c_{v,m}} = \frac{0.2323 \text{ Btu/lbm}\cdot\text{R}}{0.1704 \text{ Btu/lbm}\cdot\text{R}} = 1.363$$

Therefore, the N_2 - CO_2 mixture can be treated as a single ideal gas with above properties. Then the isentropic exit temperature can be determined from

$$T_{2s} = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (1400 \text{ R}) \left(\frac{12 \text{ psia}}{60 \text{ psia}} \right)^{0.363/1.363} = 911.7 \text{ R}$$

From the definition of isentropic efficiency,

$$\eta_N = \frac{h_1 - h_2}{h_1 - h_{2s}} = \frac{c_p(T_1 - T_2)}{c_p(T_1 - T_{2s})} \longrightarrow 0.88 = \frac{1400 - T_2}{1400 - 911.7} \longrightarrow T_2 = \mathbf{970.3 \text{ R}}$$

(b) Noting that, $q = w = 0$, from the steady-flow energy balance relation,

$$\begin{aligned} \dot{E}_{in} - \dot{E}_{out} &= \Delta \dot{E}_{system} \stackrel{\phi^0(\text{steady})}{=} 0 \\ \dot{E}_{in} &= \dot{E}_{out} \end{aligned}$$

$$h_1 + V_1^2 / 2 = h_2 + V_2^2 / 2$$

$$0 = c_p(T_2 - T_1) + \frac{V_2^2 - V_1^2}{2} \stackrel{\phi^0}{}$$

$$V_2 = \sqrt{2c_p(T_1 - T_2)} = \sqrt{2(0.2323 \text{ Btu/lbm}\cdot\text{R})(1400 - 970.3) \text{ R} \left(\frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right)} = \mathbf{2236 \text{ ft/s}}$$

13-65E Problem 13-64E is reconsidered. The problem is first to be solved and then, for all other conditions being the same, the problem is to be resolved to determine the composition of the nitrogen and carbon dioxide that is required to have an exit velocity of 2200 ft/s at the nozzle exit.

Analysis The problem is solved using EES, and the solution is given below.

"Given"

mf_N2=0.65
 mf_CO2=1-mf_N2
 P1=60 [psia]
 T1=1400 [R]
 Vel1=0 [ft/s]
 P2=12 [psia]
 eta_N=0.88
 "Vel2=2200 [ft/s]"

"Properties"

c_p_N2=0.248 [Btu/lbm-R]
 c_v_N2=0.177 [Btu/lbm-R]
 c_p_CO2=0.203 [Btu/lbm-R]
 c_v_CO2=0.158 [Btu/lbm-R]
 MM_N2=28 [lbm/lbmol]
 MM_CO2=44 [lbm/lbmol]

"Analysis"

c_p_m=mf_N2*c_p_N2+mf_CO2*c_p_CO2
 c_v_m=mf_N2*c_v_N2+mf_CO2*c_v_CO2
 k_m=c_p_m/c_v_m
 T2_s=T1*(P2/P1)^((k_m-1)/k_m)
 eta_N=(T1-T2)/(T1-T2_s)
 0=c_p_m*(T2-T1)+(Vel2^2-Vel1^2)/2*Convert(ft^2/s^2, Btu/lbm)
 N_N2=mf_N2/MM_N2
 N_CO2=mf_CO2/MM_CO2
 N_total=N_N2+N_CO2
 y_N2=N_N2/N_total
 y_CO2=N_CO2/N_total

SOLUTION of the stated problem

c_p_CO2=0.203 [Btu/lbm-R]	c_p_m=0.2323 [Btu/lbm-R]	c_p_N2=0.248 [Btu/lbm-R]

13-66 A piston-cylinder device contains a gas mixture at a given state. Heat is transferred to the mixture. The amount of heat transfer and the entropy change of the mixture are to be determined.

Assumptions 1 Under specified conditions both H_2 and N_2 can be treated as ideal gases, and the mixture as an ideal gas mixture. **2** Kinetic and potential energy changes are negligible.

Properties The constant pressure specific heats of H_2 and N_2 at 450 K are 14.501 kJ/kg·K and 1.049 kJ/kg·K, respectively. (Table A-2b).

Analysis (a) Noting that $P_2 = P_1$ and $V_2 = 2V_1$,

$$\frac{P_2 V_2}{T_2} = \frac{P_1 V_1}{T_1} \longrightarrow T_2 = \frac{2V_1}{V_1} T_1 = 2T_1 = (2)(300 \text{ K}) = 600 \text{ K}$$

From the closed system energy balance relation,

$$E_{in} - E_{out} = \Delta E_{system}$$

$$Q_{in} - W_{b,out} = \Delta U \rightarrow Q_{in} = \Delta H$$

since W_b and ΔU combine into ΔH for quasi-equilibrium constant pressure processes.

$$Q_{in} = \Delta H = \Delta H_{H_2} + \Delta H_{N_2} = [mc_{p,avg}(T_2 - T_1)]_{H_2} + [mc_{p,avg}(T_2 - T_1)]_{N_2}$$

$$= (0.8 \text{ kg})(14.501 \text{ kJ/kg} \cdot \text{K})(600 - 300) \text{ K} + (1.2 \text{ kg})(1.049 \text{ kJ/kg} \cdot \text{K})(600 - 300) \text{ K}$$

$$= \mathbf{3858 \text{ kJ}}$$

(b) Noting that the total mixture pressure, and thus the partial pressure of each gas, remains constant, the entropy change of the mixture during this process is

$$\Delta S_{H_2} = [m(s_2 - s_1)]_{H_2} = m_{H_2} \left(c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \right)_{H_2} = m_{H_2} \left(c_p \ln \frac{T_2}{T_1} \right)_{H_2}$$

$$= (0.8 \text{ kg})(14.501 \text{ kJ/kg} \cdot \text{K}) \ln \frac{600 \text{ K}}{300 \text{ K}}$$

$$= 8.041 \text{ kJ/K}$$

$$\Delta S_{N_2} = [m(s_2 - s_1)]_{N_2} = m_{N_2} \left(c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \right)_{N_2} = m_{N_2} \left(c_p \ln \frac{T_2}{T_1} \right)_{N_2}$$

$$= (1.2 \text{ kg})(1.049 \text{ kJ/kg} \cdot \text{K}) \ln \frac{600 \text{ K}}{300 \text{ K}}$$

$$= 0.8725 \text{ kJ/K}$$

$$\Delta S_{total} = \Delta S_{H_2} + \Delta S_{N_2} = 8.041 \text{ kJ/K} + 0.8725 \text{ kJ/K} = \mathbf{8.91 \text{ kJ/K}}$$

13-67 The temperatures and pressures of two gases forming a mixture in a mixing chamber are given. The mixture temperature and the rate of entropy generation are to be determined.

Assumptions 1 Under specified conditions both C_2H_6 and CH_4 can be treated as ideal gases, and the mixture as an ideal gas mixture. **2** The mixing chamber is insulated and thus there is no heat transfer. **3** There are no other forms of work involved. **3** This is a steady-flow process. **4** The kinetic and potential energy changes are negligible.

Properties The specific heats of C_2H_6 and CH_4 are $1.7662 \text{ kJ/kg}\cdot^\circ\text{C}$ and $2.2537 \text{ kJ/kg}\cdot^\circ\text{C}$, respectively. (Table A-2b).

Analysis (a) The enthalpy of ideal gases is independent of pressure, and thus the two gases can be treated independently even after mixing. Noting that

$\dot{W} = \dot{Q} = 0$, the steady-flow energy balance equation reduces to

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\phi=0(\text{steady})}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e$$

$$0 = \sum \dot{m}_e h_e - \sum \dot{m}_i h_i = \dot{m}_{C_2H_6} (h_e - h_i)_{C_2H_6} + \dot{m}_{CH_4} (h_e - h_i)_{CH_4}$$

$$0 = [\dot{m} c_p (T_e - T_i)]_{C_2H_6} + [\dot{m} c_p (T_e - T_i)]_{CH_4}$$

Using c_p values at room temperature and substituting, the exit temperature of the mixture becomes

$$0 = (6 \text{ kg/s})(1.7662 \text{ kJ/kg}\cdot^\circ\text{C})(T_m - 15^\circ\text{C}) + (3 \text{ kg/s})(2.2537 \text{ kJ/kg}\cdot^\circ\text{C})(T_m - 60^\circ\text{C})$$

$$T_m = \mathbf{32.5^\circ\text{C}} \quad (305.5 \text{ K})$$

(b) The rate of entropy change associated with this process is determined from an entropy balance on the mixing chamber,

$$\dot{S}_{\text{in}} - \dot{S}_{\text{out}} + \dot{S}_{\text{gen}} = \Delta \dot{S}_{\text{system}} \stackrel{\approx 0}{=} 0$$

$$[\dot{m}(s_1 - s_2)]_{C_2H_6} + [\dot{m}(s_1 - s_2)]_{CH_4} + \dot{S}_{\text{gen}} = 0$$

$$\dot{S}_{\text{gen}} = [\dot{m}(s_2 - s_1)]_{C_2H_6} + [\dot{m}(s_2 - s_1)]_{CH_4}$$

The molar flow rate of the two gases in the mixture is

$$\dot{N}_{C_2H_6} = \left(\frac{\dot{m}}{M} \right)_{C_2H_6} = \frac{6 \text{ kg/s}}{30 \text{ kg/kmol}} = 0.2 \text{ kmol/s}$$

$$\dot{N}_{CH_4} = \left(\frac{\dot{m}}{M} \right)_{CH_4} = \frac{4.5 \text{ kg/s}}{16 \text{ kg/kmol}} = 0.1875 \text{ kmol/s}$$

Then the mole fraction of each gas becomes

$$y_{C_2H_6} = \frac{0.2}{0.2 + 0.1875} = 0.5161$$

$$y_{CH_4} = \frac{0.1875}{0.2 + 0.1875} = 0.4839$$

Thus,

$$\begin{aligned} (s_2 - s_1)_{C_2H_6} &= \left(c_p \ln \frac{T_2}{T_1} - R \ln \frac{y P_{m,2}}{P_1} \right)_{C_2H_6} = \left(c_p \ln \frac{T_2}{T_1} - R \ln y \right)_{C_2H_6} \\ &= (1.7662 \text{ kJ/kg}\cdot\text{K}) \ln \frac{305.5 \text{ K}}{288 \text{ K}} - (0.2765 \text{ kJ/kg}\cdot\text{K}) \ln(0.5161) = 0.2872 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

$$\begin{aligned} (s_2 - s_1)_{CH_4} &= \left(c_p \ln \frac{T_2}{T_1} - R \ln \frac{y P_{m,2}}{P_1} \right)_{CH_4} = \left(c_p \ln \frac{T_2}{T_1} - R \ln y \right)_{CH_4} \\ &= (2.2537 \text{ kJ/kg}\cdot\text{K}) \ln \frac{305.5 \text{ K}}{333 \text{ K}} - (0.5182 \text{ kJ/kg}\cdot\text{K}) \ln(0.4839) = 0.1821 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

Noting that $P_{m,2} = P_{i,1} = 300 \text{ kPa}$ and substituting,

$$\dot{S}_{\text{gen}} = (6 \text{ kg/s})(0.2872 \text{ kJ/kg}\cdot\text{K}) + (3 \text{ kg/s})(0.1821 \text{ kJ/kg}\cdot\text{K}) = \mathbf{2.27 \text{ kW/K}}$$

13-68 Problem 13-67 is reconsidered. The effect of the mass fraction of methane in the mixture on the mixture temperature and the rate of exergy destruction is to be investigated.

Analysis The problem is solved using EES, and the solution is given below.

"Given"

"1: C2H6, 2: CH4"

$m_{\text{dot_total}}=9$ [kg/s]

"mf_CH4=0.3333"

$mf_{\text{C2H6}}=1-mf_{\text{CH4}}$

$m_{\text{dot_1}}=mf_{\text{C2H6}}*m_{\text{dot_total}}$

$m_{\text{dot_2}}=mf_{\text{CH4}}*m_{\text{dot_total}}$

$T1=(15+273)$ [K]

$T2=(60+273)$ [K]

$P=300$ [kPa]

$T0=(25+273)$ [K]

"Properties"

13-69E In an air-liquefaction plant, it is proposed that the pressure and temperature of air be adiabatically reduced. It is to be determined whether this process is possible and the work produced is to be determined using Kay's rule and the departure charts.

Assumptions Air is a gas mixture with 21% O₂ and 79% N₂, by mole.

Properties The molar masses of O₂ and N₂ are 32.0 and 28.0 lbm/lbmol, respectively. The critical properties are 278.6 R, 736 psia for O₂ and 227.1 R and 492 psia for N₂ (Table A-1E).

Analysis To use Kay's rule, we need to determine the pseudo-critical temperature and pseudo-critical pressure of the mixture using the critical point properties of gases.

$$T'_{cr,m} = \sum y_i T_{cr,i} = y_{O_2} T_{cr,O_2} + y_{N_2} T_{cr,N_2}$$

$$= (0.21)(278.6 \text{ R}) + (0.79)(227.1 \text{ R}) = 237.9 \text{ R}$$

$$P'_{cr,m} = \sum y_i P_{cr,i} = y_{O_2} P_{cr,O_2} + y_{N_2} P_{cr,N_2}$$

$$= (0.21)(736 \text{ psia}) + (0.79)(492 \text{ psia}) = 543.2 \text{ psia}$$

21% O₂
79% N₂
(by mole)
1500 psia
40°F

The enthalpy and entropy departure factors at the initial and final states are (from EES)

$$\left. \begin{aligned} T_{R1} &= \frac{T_{m1}}{T'_{cr,m}} = \frac{500 \text{ R}}{237.9 \text{ R}} = 2.102 \\ P_{R1} &= \frac{P_{m1}}{P'_{cr,m}} = \frac{1500 \text{ psia}}{432.2 \text{ psia}} = 3.471 \end{aligned} \right\} \begin{aligned} Z_{h1} &= 0.725 \\ Z_{s1} &= 0.339 \end{aligned}$$

$$\left. \begin{aligned} T_{R2} &= \frac{T_{m2}}{T'_{cr,m}} = \frac{360 \text{ R}}{237.9 \text{ R}} = 1.513 \\ P_{R2} &= \frac{P_{m2}}{P'_{cr,m}} = \frac{15 \text{ psia}}{432.2 \text{ psia}} = 0.0347 \end{aligned} \right\} \begin{aligned} Z_{h2} &= 0.0179 \\ Z_{s2} &= 0.00906 \end{aligned}$$

The enthalpy and entropy changes of the air under the ideal gas assumption is (Properties are from Table A-17E)

$$(h_2 - h_1)_{ideal} = 85.97 - 119.48 = -33.5 \text{ Btu/lbm}$$

$$(s_2 - s_1)_{ideal} = s_2^o - s_1^o - R \ln \frac{P_2}{P_1} = 0.50369 - 0.58233 - (0.06855) \ln \frac{15}{1500} = 0.2370 \text{ Btu/lbm} \cdot \text{R}$$

With departure factors, the enthalpy change (i.e., the work output) and the entropy change are

$$w_{out} = h_1 - h_2 = (h_1 - h_2)_{ideal} - RT'_{cr} (Z_{h1} - Z_{h2})$$

$$= 33.5 - (0.06855)(237.9)(0.725 - 0.0179)$$

$$= \mathbf{22.0 \text{ Btu/lbm}}$$

$$s_2 - s_1 = (s_2 - s_1)_{ideal} - R(Z_{s2} - Z_{s1})$$

$$= 0.2370 - (0.06855)(0.00906 - 0.339)$$

$$= \mathbf{0.2596 \text{ Btu/lbm} \cdot \text{R}}$$

The entropy change in this case is equal to the entropy generation during the process since the process is adiabatic. The positive value of entropy generation shows that this process is possible.

13-70 Heat is transferred to a gas mixture contained in a piston cylinder device. The initial state and the final temperature are given. The heat transfer is to be determined for the ideal gas and non-ideal gas cases.

Properties The molar masses of H₂ and N₂ are 2.0, and 28.0 kg/kmol. (Table A-1).

Analysis From the energy balance relation,

$$\begin{aligned} E_{\text{in}} - E_{\text{out}} &= \Delta E \\ Q_{\text{in}} - W_{b,\text{out}} &= \Delta U \\ Q_{\text{in}} &= \Delta H = \Delta H_{\text{H}_2} + \Delta H_{\text{N}_2} = N_{\text{H}_2}(\bar{h}_2 - \bar{h}_1)_{\text{H}_2} + N_{\text{N}_2}(\bar{h}_2 - \bar{h}_1)_{\text{N}_2} \end{aligned}$$

since W_b and ΔU combine into ΔH for quasi-equilibrium constant pressure processes

$$\begin{aligned} N_{\text{H}_2} &= \frac{m_{\text{H}_2}}{M_{\text{H}_2}} = \frac{6 \text{ kg}}{2 \text{ kg/kmol}} = 3 \text{ kmol} \\ N_{\text{N}_2} &= \frac{m_{\text{N}_2}}{M_{\text{N}_2}} = \frac{21 \text{ kg}}{28 \text{ kg/kmol}} = 0.75 \text{ kmol} \end{aligned}$$

(a) Assuming ideal gas behavior, the inlet and exit enthalpies of H₂ and N₂ are determined from the ideal gas tables to be

$$\begin{aligned} \text{H}_2: \quad \bar{h}_1 &= \bar{h}_{@160 \text{ K}} = 4,535.4 \text{ kJ/kmol}, & \bar{h}_2 &= \bar{h}_{@200 \text{ K}} = 5,669.2 \text{ kJ/kmol} \\ \text{N}_2: \quad \bar{h}_1 &= \bar{h}_{@160 \text{ K}} = 4,648 \text{ kJ/kmol}, & \bar{h}_2 &= \bar{h}_{@200 \text{ K}} = 5,810 \text{ kJ/kmol} \end{aligned}$$

Thus, $Q_{\text{ideal}} = 3 \times (5,669.2 - 4,535.4) + 0.75 \times (5,810 - 4,648) = \mathbf{4273 \text{ kJ}}$

(b) Using Amagat's law and the generalized enthalpy departure chart, the enthalpy change of each gas is determined to be

$$\text{H}_2: \left. \begin{aligned} T_{R_1, \text{H}_2} &= \frac{T_{m,1}}{T_{\text{cr}, \text{H}_2}} = \frac{160}{33.3} = 4.805 \\ P_{R_1, \text{H}_2} &= P_{R_2, \text{H}_2} = \frac{P_m}{P_{\text{cr}, \text{H}_2}} = \frac{5}{1.30} = 3.846 \\ T_{R_2, \text{H}_2} &= \frac{T_{m,2}}{T_{\text{cr}, \text{H}_2}} = \frac{200}{33.3} = 6.006 \end{aligned} \right\} \begin{aligned} Z_{h_1} &\cong 0 \\ Z_{h_2} &\cong 0 \end{aligned} \quad (\text{Fig. A-29})$$

Thus H₂ can be treated as an ideal gas during this process.

$$\text{N}_2: \left. \begin{aligned} T_{R_1, \text{N}_2} &= \frac{T_{m,1}}{T_{\text{cr}, \text{N}_2}} = \frac{160}{126.2} = 1.27 \\ P_{R_1, \text{N}_2} &= P_{R_2, \text{N}_2} = \frac{P_m}{P_{\text{cr}, \text{N}_2}} = \frac{5}{3.39} = 1.47 \\ T_{R_2, \text{N}_2} &= \frac{T_{m,2}}{T_{\text{cr}, \text{N}_2}} = \frac{200}{126.2} = 1.58 \end{aligned} \right\} \begin{aligned} Z_{h_1} &= 1.3 \\ Z_{h_2} &= 0.7 \end{aligned} \quad (\text{Fig. A-29})$$

Therefore,

$$\begin{aligned} (\bar{h}_2 - \bar{h}_1)_{\text{H}_2} &= (\bar{h}_2 - \bar{h}_1)_{\text{H}_2, \text{ideal}} = 5,669.2 - 4,535.4 = 1,133.8 \text{ kJ/kmol} \\ (\bar{h}_2 - \bar{h}_1)_{\text{N}_2} &= R_u T_{\text{cr}} (Z_{h_1} - Z_{h_2}) + (\bar{h}_2 - \bar{h}_1)_{\text{ideal}} \\ &= (8.314 \text{ kPa} \cdot \text{m}^3 / \text{kmol} \cdot \text{K})(126.2 \text{ K})(1.3 - 0.7) + (5,810 - 4,648) \text{ kJ/kmol} = 1,791.5 \text{ kJ/kmol} \end{aligned}$$

Substituting,

$$Q_{\text{in}} = (3 \text{ kmol})(1,133.8 \text{ kJ/kmol}) + (0.75 \text{ kmol})(1,791.5 \text{ kJ/kmol}) = \mathbf{4745 \text{ kJ}}$$

13-71 Heat is transferred to a gas mixture contained in a piston cylinder device discussed in previous problem. The total entropy change and the exergy destruction are to be determined for two cases.

Analysis The entropy generated during this process is determined by applying the entropy balance on an *extended system* that includes the piston-cylinder device and its immediate surroundings so that the boundary temperature of the extended system is the environment temperature at all times. It gives

$$S_{\text{in}} - S_{\text{out}} + S_{\text{gen}} = \Delta S_{\text{system}}$$

$$\frac{Q_{\text{in}}}{T_{\text{boundary}}} + S_{\text{gen}} = \Delta S_{\text{water}} \rightarrow S_{\text{gen}} = m(s_2 - s_1) - \frac{Q_{\text{in}}}{T_{\text{surr}}}$$

Then the exergy destroyed during a process can be determined from its definition $X_{\text{destroyed}} = T_0 S_{\text{gen}}$.

(a) Noting that the total mixture pressure, and thus the partial pressure of each gas, remains constant, the entropy change of a component in the mixture during this process is

$$\Delta S_i = m_i \left(c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \right) = m_i c_{p,i} \ln \frac{T_2}{T_1}$$

Assuming ideal gas behavior and using c_p values at the average temperature, the ΔS of H_2 and N_2 are determined from

$$\Delta S_{\text{H}_2, \text{ideal}} = (6 \text{ kg})(13.60 \text{ kJ/kg} \cdot \text{K}) \ln \frac{200 \text{ K}}{160 \text{ K}} = 18.21 \text{ kJ/K}$$

$$\Delta S_{\text{N}_2, \text{ideal}} = (21 \text{ kg})(1.039 \text{ kJ/kg} \cdot \text{K}) \ln \frac{200 \text{ K}}{160 \text{ K}} = 4.87 \text{ kJ/K}$$

and

$$S_{\text{gen}} = 18.21 \text{ kJ/K} + 4.87 \text{ kJ/K} - \frac{4273 \text{ kJ}}{293 \text{ K}} = \mathbf{8.496 \text{ kJ/K}}$$

$$X_{\text{destroyed}} = T_0 S_{\text{gen}} = (293 \text{ K})(8.496 \text{ kJ/K}) = \mathbf{2489 \text{ kJ}}$$

(b) Using Amagat's law and the generalized entropy departure chart, the entropy change of each gas is determined to be

$$\text{H}_2: \left. \begin{aligned} T_{R_1, \text{H}_2} &= \frac{T_{m,1}}{T_{\text{cr}, \text{H}_2}} = \frac{160}{33.3} = 4.805 \\ P_{R_1, \text{H}_2} &= P_{R_2, \text{H}_2} = \frac{P_m}{P_{\text{cr}, \text{H}_2}} = \frac{5}{1.30} = 3.846 \\ T_{R_2, \text{H}_2} &= \frac{T_{m,2}}{T_{\text{cr}, \text{H}_2}} = \frac{200}{33.3} = 6.006 \end{aligned} \right\} \begin{aligned} Z_{s_1} &\cong 1 \\ Z_{s_2} &\cong 1 \end{aligned} \quad (\text{Table A-30})$$

Thus H_2 can be treated as an ideal gas during this process.

$$\text{N}_2: \left. \begin{aligned} T_{R_1, \text{N}_2} &= \frac{T_{m,1}}{T_{\text{cr}, \text{N}_2}} = \frac{160}{126.2} = 1.268 \\ P_{R_1, \text{N}_2} &= P_{R_2, \text{N}_2} = \frac{P_m}{P_{\text{cr}, \text{N}_2}} = \frac{5}{3.39} = 1.475 \\ T_{R_2, \text{N}_2} &= \frac{T_{m,2}}{T_{\text{cr}, \text{N}_2}} = \frac{200}{126.2} = 1.585 \end{aligned} \right\} \begin{aligned} Z_{s_1} &= 0.8 \\ Z_{s_2} &= 0.4 \end{aligned} \quad (\text{Table A-30})$$

Therefore,

$$\Delta S_{\text{H}_2} = \Delta S_{\text{H}_2, \text{ideal}} = 18.21 \text{ kJ/K}$$

$$\begin{aligned} \Delta S_{\text{N}_2} &= N_{\text{N}_2} R_u (Z_{s_1} - Z_{s_2}) + \Delta S_{\text{N}_2, \text{ideal}} \\ &= (0.75 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(0.8 - 0.4) + (4.87 \text{ kJ/K}) \\ &= 7.37 \text{ kJ/K} \end{aligned}$$

$$\Delta S_{\text{sur}} = \frac{Q_{\text{sur}}}{T_0} = \frac{-4745 \text{ kJ}}{293 \text{ K}} = -16.19 \text{ kJ/K}$$

and

$$S_{\text{gen}} = 18.21 \text{ kJ/K} + 7.37 \text{ kJ/K} - 16.19 = \mathbf{9.390 \text{ kJ/K}}$$

$$X_{\text{destroyed}} = T_0 S_{\text{gen}} = (293 \text{ K})(9.385 \text{ kJ/K}) = \mathbf{2751 \text{ kJ}}$$

13-72 Two mass streams of two different ideal gases are mixed in a steady-flow chamber while receiving energy by heat transfer from the surroundings. Expressions for the final temperature and the exit volume flow rate are to be obtained and two special cases are to be evaluated.

Assumptions Kinetic and potential energy changes are negligible.

Analysis (a) Mass and energy balances for the mixing process:

$$\dot{m}_1 + \dot{m}_2 = \dot{m}_3$$

$$\dot{m}_1 h_1 + \dot{m}_2 h_2 + \dot{Q}_{in} = \dot{m}_3 h_3$$

$$h = C_p T$$

$$\dot{m}_1 C_{p,1} T_1 + \dot{m}_2 C_{p,2} T_2 + \dot{Q}_{in} = \dot{m}_3 C_{p,m} T_3$$

$$C_{p,m} = \frac{\dot{m}_1}{\dot{m}_3} C_{p,1} + \frac{\dot{m}_2}{\dot{m}_3} C_{p,2}$$

$$T_3 = \frac{\dot{m}_1 C_{p,1}}{\dot{m}_3 C_{p,m}} T_1 + \frac{\dot{m}_2 C_{p,2}}{\dot{m}_3 C_{p,m}} T_2 + \frac{\dot{Q}_{in}}{\dot{m}_3 C_{p,m}}$$

(b) The expression for the exit volume flow rate is obtained as follows:

$$\dot{V}_3 = \dot{m}_3 v_3 = \dot{m}_3 \frac{R_3 T_3}{P_3}$$

$$\dot{V}_3 = \frac{\dot{m}_3 R_3}{P_3} \left[\frac{\dot{m}_1 C_{p,1}}{\dot{m}_3 C_{p,m}} T_1 + \frac{\dot{m}_2 C_{p,2}}{\dot{m}_3 C_{p,m}} T_2 + \frac{\dot{Q}_{in}}{\dot{m}_3 C_{p,m}} \right]$$

$$\dot{V}_3 = \frac{C_{p,1} R_3}{C_{p,m} R_1} \frac{\dot{m}_1 R_1 T_1}{P_3} + \frac{C_{p,2} R_3}{C_{p,m} R_2} \frac{\dot{m}_2 R_2 T_2}{P_3} + \frac{R_3 \dot{Q}_{in}}{P_3 C_{p,m}}$$

$$P_3 = P_1 = P_2$$

$$\dot{V}_3 = \frac{C_{p,1} R_3}{C_{p,m} R_1} \dot{V}_1 + \frac{C_{p,2} R_3}{C_{p,m} R_2} \dot{V}_2 + \frac{R_3 \dot{Q}_{in}}{P_3 C_{p,m}}$$

$$R = \frac{R_u}{M}, \quad \frac{R_3}{R_1} = \frac{R_u}{M_3} \frac{M_1}{R_u} = \frac{M_1}{M_3}, \quad \frac{R_3}{R_2} = \frac{M_2}{M_3}$$

$$\dot{V}_3 = \frac{C_{p,1} M_1}{C_{p,m} M_3} \dot{V}_1 + \frac{C_{p,2} M_2}{C_{p,m} M_3} \dot{V}_2 + \frac{R_u \dot{Q}_{in}}{P_3 M_3 C_{p,m}}$$

The mixture molar mass M_3 is found as follows:

$$M_3 = \sum y_i M_i, \quad y_i = \frac{m_{fi} / M_i}{\sum m_{fi} / M_i}, \quad m_{fi} = \sum \dot{m}_i$$

(c) For adiabatic mixing \dot{Q}_{in} is zero, and the mixture volume flow rate becomes

$$\dot{V}_3 = \frac{C_{p,1} M_1}{C_{p,m} M_3} \dot{V}_1 + \frac{C_{p,2} M_2}{C_{p,m} M_3} \dot{V}_2$$

(d) When adiabatically mixing the same two ideal gases, the mixture volume flow rate becomes

$$M_3 = M_1 = M_2$$

$$C_{p,3} = C_{p,1} = C_{p,2}$$

$$\dot{V}_3 = \dot{V}_1 + \dot{V}_2$$

Special Topic: Chemical Potential and the Separation Work of Mixtures

13-73C No, a process that separates a mixture into its components without requiring any work (exergy) input is impossible since such a process would violate the 2nd law of thermodynamics.

13-74C Yes, the volume of the mixture can be more or less than the sum of the initial volumes of the mixing liquids because of the attractive or repulsive forces acting between dissimilar molecules.

13-75C The person who claims that the temperature of the mixture can be higher than the temperatures of the components is right since the total enthalpy of the mixture of two components at the same pressure and temperature, in general, is not equal to the sum of the total enthalpies of the individual components before mixing, the difference being the enthalpy (or heat) of mixing, which is the heat released or absorbed as two or more components are mixed isothermally.

13-76C Mixtures or solutions in which the effects of molecules of different components on each other are negligible are called ideal solutions (or ideal mixtures). The ideal-gas mixture is just one category of ideal solutions. For ideal solutions, the enthalpy change and the volume change due to mixing are zero, but the entropy change is not. The chemical potential of a component of an ideal mixture is independent of the identity of the other constituents of the mixture. The chemical potential of a component in an ideal mixture is equal to the Gibbs function of the pure component.

13-77 Brackish water is used to produce fresh water. The minimum power input and the minimum height the brackish water must be raised by a pump for reverse osmosis are to be determined.

Assumptions 1 The brackish water is an ideal solution since it is dilute. **2** The total dissolved solids in water can be treated as table salt (NaCl). **3** The environment temperature is also 18°C.

Properties The molar masses of water and salt are $M_w = 18.0 \text{ kg/kmol}$ and $M_s = 58.44 \text{ kg/kmol}$. The gas constant of pure water is $R_w = 0.4615 \text{ kJ/kg}\cdot\text{K}$ (Table A-1). The density of fresh water is 1000 kg/m^3 .

Analysis First we determine the mole fraction of pure water in brackish water using Eqs. 13-4 and 13-5. Noting that $mf_s = 0.00078$ and $mf_w = 1 - mf_s = 0.99922$,

$$M_m = \frac{1}{\sum \frac{mf_i}{M_i}} = \frac{1}{\frac{mf_s}{M_s} + \frac{mf_w}{M_w}} = \frac{1}{\frac{0.00078}{58.44} + \frac{0.99922}{18.0}} = 18.01 \text{ kg/kmol}$$

$$y_i = mf_i \frac{M_m}{M_i} \rightarrow y_w = mf_w \frac{M_m}{M_w} = (0.99922) \frac{18.01 \text{ kg/kmol}}{18.0 \text{ kg/kmol}} = 0.99976$$

The minimum work input required to produce 1 kg of freshwater from brackish water is

$$w_{\min, \text{in}} = R_w T_0 \ln(1/y_w) = (0.4615 \text{ kJ/kg}\cdot\text{K})(291.15 \text{ K}) \ln(1/0.99976) = 0.03230 \text{ kJ/kg fresh water}$$

Therefore, 0.03159 kJ of work is needed to produce 1 kg of fresh water is mixed with seawater reversibly. Therefore, the required power input to produce fresh water at the specified rate is

$$\dot{W}_{\min, \text{in}} = \rho \dot{V} w_{\min, \text{in}} = (1000 \text{ kg/m}^3)(0.175 \text{ m}^3/\text{s})(0.03230 \text{ kJ/kg}) \left(\frac{1 \text{ kW}}{1 \text{ kJ/s}} \right) = \mathbf{5.65 \text{ kW}}$$

The minimum height to which the brackish water must be pumped is

$$\Delta z_{\min} = \frac{w_{\min, \text{in}}}{g} = \left(\frac{0.03230 \text{ kJ/kg}}{9.81 \text{ m/s}^2} \right) \left(\frac{1 \text{ kg}\cdot\text{m/s}^2}{1 \text{ N}} \right) \left(\frac{1000 \text{ N}\cdot\text{m}}{1 \text{ kJ}} \right) = \mathbf{3.29 \text{ m}}$$

13-78 A river is discharging into the ocean at a specified rate. The amount of power that can be generated is to be determined.

Assumptions 1 The seawater is an ideal solution since it is dilute. **2** The total dissolved solids in water can be treated as table salt (NaCl). **3** The environment temperature is also 15°C.

Properties The molar masses of water and salt are $M_w = 18.0 \text{ kg/kmol}$ and $M_s = 58.44 \text{ kg/kmol}$. The gas constant of pure water is $R_w = 0.4615 \text{ kJ/kg}\cdot\text{K}$ (Table A-1). The density of river water is 1000 kg/m^3 .

Analysis First we determine the mole fraction of pure water in ocean water using Eqs. 13-4 and 13-5. Noting that $mf_s = 0.025$ and $mf_w = 1 - mf_s = 0.975$,

$$M_m = \frac{1}{\sum \frac{mf_i}{M_i}} = \frac{1}{\frac{mf_s}{M_s} + \frac{mf_w}{M_w}} = \frac{1}{\frac{0.025}{58.44} + \frac{0.975}{18.0}} = 18.32 \text{ kg/kmol}$$

$$y_i = mf_i \frac{M_m}{M_i} \rightarrow y_w = mf_w \frac{M_m}{M_w} = (0.975) \frac{18.32 \text{ kg/kmol}}{18.0 \text{ kg/kmol}} = 0.9922$$

The maximum work output associated with mixing 1 kg of seawater (or the minimum work input required to produce 1 kg of freshwater from seawater) is

$$w_{\max, \text{out}} = R_w T_0 \ln(1/y_w) = (0.4615 \text{ kJ/kg}\cdot\text{K})(288.15 \text{ K})\ln(1/0.9922) = 1.046 \text{ kJ/kg fresh water}$$

Therefore, 1.046 kJ of work can be produced as 1 kg of fresh water is mixed with seawater reversibly. Therefore, the power that can be generated as a river with a flow rate of $400,000 \text{ m}^3/\text{s}$ mixes reversibly with seawater is

$$\dot{W}_{\max \text{ out}} = \rho \dot{V} w_{\max \text{ out}} = (1000 \text{ kg/m}^3)(1.5 \times 10^5 \text{ m}^3/\text{s})(1.046 \text{ kJ/kg}) \left(\frac{1 \text{ kW}}{1 \text{ kJ/s}} \right) = \mathbf{157 \times 10^6 \text{ kW}}$$

Discussion This is more power than produced by all nuclear power plants (112 of them) in the U.S., which shows the tremendous amount of power potential wasted as the rivers discharge into the seas.

13-79  Problem 13-78 is reconsidered. The effect of the salinity of the ocean on the maximum power generated is to be investigated.

Analysis The problem is solved using EES, and the solution is given below.

"Given"

$$V_{\dot{}}=150000 \text{ [m}^3\text{/s]}$$

"salinity=2.5"

$$T=(15+273.15) \text{ [K]}$$

"Properties"

$$M_w=18 \text{ [kg/kmol]} \text{ "molar mass (H}_2\text{O)"}$$

$$M_s=58.44 \text{ [kg/kmol]} \text{ "molar mass of salt"}$$

$$R_w=0.4615 \text{ [kJ/kg-K]} \text{ "gas constant of water"}$$

$$\rho=1000 \text{ [kg/m}^3\text{]}$$

"Analysis"

$$\text{mass}_w=100-\text{salinity}$$

$$\text{mf}_s=\text{salinity}/100$$

$$\text{mf}_w=\text{mass}_w/100$$

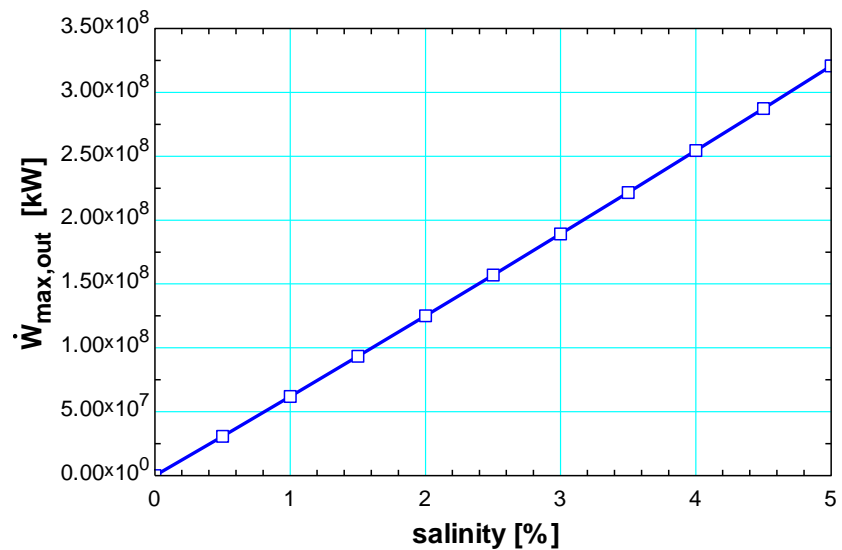

$$M_m=1/(\text{mf}_s/M_s+\text{mf}_w/M_w)$$

$$y_w=\text{mf}_w*M_m/M_w$$

$$w_{\text{max,out}}=R_w*T*\ln(1/y_w)$$

$$W_{\dot{\text{max,out}}}=\rho*V_{\dot{}}*w_{\text{max,out}}$$

Salinity [%]	$W_{\text{max,out}}$ [kW]
0	0

13-80E Brackish water is used to produce fresh water. The mole fractions, the minimum work inputs required to separate 1 lbm of brackish water and to obtain 1 lbm of fresh water are to be determined.

Assumptions 1 The brackish water is an ideal solution since it is dilute. **2** The total dissolved solids in water can be treated as table salt (NaCl). **3** The environment temperature is equal to the water temperature.

Properties The molar masses of water and salt are $M_w = 18.0$ lbm/lbmol and $M_s = 58.44$ lbm/lbmol. The gas constant of pure water is $R_w = 0.1102$ Btu/lbm·R (Table A-1E).

Analysis (a) First we determine the mole fraction of pure water in brackish water using Eqs. 13-4 and 13-5. Noting that $mf_s = 0.0012$ and $mf_w = 1 - mf_s = 0.9988$,

$$M_m = \frac{1}{\sum \frac{mf_i}{M_i}} = \frac{1}{\frac{mf_s}{M_s} + \frac{mf_w}{M_w}} = \frac{1}{\frac{0.0012}{58.44} + \frac{0.9988}{18.0}} = 18.015 \text{ lbm/lbmol}$$

$$y_i = mf_i \frac{M_m}{M_i} \rightarrow y_w = mf_w \frac{M_m}{M_w} = (0.9988) \frac{18.015 \text{ lbm/lbmol}}{18.0 \text{ lbm/lbmol}} = \mathbf{0.99963}$$

$$y_s = 1 - y_w = 1 - 0.99963 = \mathbf{0.00037}$$

(b) The minimum work input required to separate 1 lbmol of brackish water is

$$\begin{aligned} w_{\min, \text{in}} &= -R_w T_0 (y_w \ln y_w + y_s \ln y_s) \\ &= -(0.1102 \text{ Btu/lbmol}\cdot\text{R})(525 \text{ R})[0.99963 \ln(0.99963) + 0.00037 \ln(0.00037)] \\ &= \mathbf{-0.191 \text{ Btu/lbm brackish water}} \end{aligned}$$

(c) The minimum work input required to produce 1 lbm of freshwater from brackish water is

$$w_{\min, \text{in}} = R_w T_0 \ln(1/y_w) = (0.1102 \text{ Btu/lbm}\cdot\text{R})(525 \text{ R}) \ln(1/0.99963) = \mathbf{0.0214 \text{ Btu/lbm fresh water}}$$

Discussion Note that it takes about 9 times work to separate 1 lbm of brackish water into pure water and salt compared to producing 1 lbm of fresh water from a large body of brackish water.

13-81 A desalination plant produces fresh water from seawater. The second law efficiency of the plant is to be determined.

Assumptions 1 The seawater is an ideal solution since it is dilute. **2** The total dissolved solids in water can be treated as table salt (NaCl). **3** The environment temperature is equal to the seawater temperature.

Properties The molar masses of water and salt are $M_w = 18.0 \text{ kg/kmol}$ and $M_s = 58.44 \text{ kg/kmol}$. The gas constant of pure water is $R_w = 0.4615 \text{ kJ/kg}\cdot\text{K}$ (Table A-1). The density of river water is 1000 kg/m^3 .

Analysis First we determine the mole fraction of pure water in seawater using Eqs. 13-4 and 13-5. Noting that $mf_s = 0.032$ and $mf_w = 1 - mf_s = 0.968$,

$$M_m = \frac{1}{\sum \frac{mf_i}{M_i}} = \frac{1}{\frac{mf_s}{M_s} + \frac{mf_w}{M_w}} = \frac{1}{\frac{0.032}{58.44} + \frac{0.968}{18.0}} = 18.41 \text{ kg/kmol}$$

$$y_i = mf_i \frac{M_m}{M_i} \rightarrow y_w = mf_w \frac{M_m}{M_w} = (0.968) \frac{18.41 \text{ kg/kmol}}{18.0 \text{ kg/kmol}} = 0.9900$$

The maximum work output associated with mixing 1 kg of seawater (or the minimum work input required to produce 1 kg of freshwater from seawater) is

$$w_{\max, \text{out}} = R_w T_0 \ln(1/y_w) = (0.4615 \text{ kJ/kg}\cdot\text{K})(283.15 \text{ K})\ln(1/0.990) = 1.313 \text{ kJ/kg fresh water}$$

The power that can be generated as $1.4 \text{ m}^3/\text{s}$ fresh water mixes reversibly with seawater is

$$\dot{W}_{\max \text{ out}} = \rho \dot{V} w_{\max \text{ out}} = (1000 \text{ kg/m}^3)(1.4 \text{ m}^3/\text{s})(1.313 \text{ kJ/kg}) \left(\frac{1 \text{ kW}}{1 \text{ kJ/s}} \right) = 1.84 \text{ kW}$$

Then the second law efficiency of the plant becomes

$$\eta_{\text{II}} = \frac{\dot{W}_{\min, \text{in}}}{\dot{W}_{\text{in}}} = \frac{1.83 \text{ MW}}{8.5 \text{ MW}} = 0.216 = \mathbf{21.6\%}$$

13-82 The power consumption and the second law efficiency of a desalination plant are given. The power that can be produced if the fresh water produced is mixed with the seawater reversibly is to be determined.

Assumptions 1 This is a steady-flow process. **2** The kinetic and potential energy changes are negligible.

Analysis From the definition of the second law efficiency

$$\eta_{\text{II}} = \frac{\dot{W}_{\text{rev}}}{\dot{W}_{\text{actual}}} \rightarrow 0.20 = \frac{\dot{W}_{\text{rev}}}{11,500 \text{ kW}} \rightarrow \dot{W}_{\text{rev}} = \mathbf{2300 \text{ kW}}$$

which is the maximum power that can be generated.

13-83E It is to be determined if it is possible for an adiabatic liquid-vapor separator to separate wet steam at 100 psia and 90 percent quality, so that the pressure of the outlet streams is greater than 100 psia.

Analysis Because the separator divides the inlet stream into the liquid and vapor portions,

$$\dot{m}_2 = x\dot{m}_1 = 0.9\dot{m}_1$$

$$\dot{m}_3 = (1-x)\dot{m}_1 = 0.1\dot{m}_1$$

According to the water property tables at 100 psia (Table A-5E),

$$s_1 = s_f + xs_{fg} = 0.47427 + 0.9 \times 1.12888 = 1.4903 \text{ Btu/lbm} \cdot \text{R}$$

When the increase in entropy principle is adapted to this system, it becomes

$$\begin{aligned} \dot{m}_2 s_2 + \dot{m}_3 s_3 &\geq \dot{m}_1 s_1 \\ x\dot{m}_1 s_2 + (1-x)\dot{m}_1 s_3 &\geq \dot{m}_1 s_1 \\ 0.9s_2 + 0.1s_3 &\geq s_1 \\ &\geq 1.4903 \text{ Btu/lbm} \cdot \text{R} \end{aligned}$$

To test this hypothesis, let's assume the outlet pressures are 110 psia. Then,

$$s_2 = s_g = 1.5954 \text{ Btu/lbm} \cdot \text{R}$$

$$s_3 = s_f = 0.48341 \text{ Btu/lbm} \cdot \text{R}$$

The left-hand side of the above equation is

$$0.9s_2 + 0.1s_3 = 0.9 \times 1.5954 + 0.1 \times 0.48341 = 1.4842 \text{ Btu/lbm} \cdot \text{R}$$

which is less than the minimum possible specific entropy. Hence, the outlet pressure cannot be 110 psia. Inspection of the water table in light of above equation proves that the pressure at the separator outlet cannot be greater than that at the inlet.

Review Problems

13-84 The volume fractions of components of a gas mixture are given. The mole fractions, the mass fractions, the partial pressures, the mixture molar mass, apparent gas constant, and constant-pressure specific heat are to be determined and compared to the values in Table A-2a.

Properties The molar masses of N_2 , O_2 and Ar are 28.0, 32.0, and 40.0 kg/kmol, respectively (Table A-1). The constant-pressure specific heats of these gases at 300 K are 1.039, 0.918, and 0.5203 kJ/kg·K, respectively (Table A-2a).

Analysis The volume fractions are equal to the mole fractions:

$$y_{N_2} = \mathbf{0.78}, \quad y_{O_2} = \mathbf{0.21}, \quad y_{Ar} = \mathbf{0.01}$$

The volume fractions are equal to the pressure fractions. The partial pressures are then

$$P_{N_2} = y_{N_2} P_{\text{total}} = (0.78)(100 \text{ kPa}) = \mathbf{78 \text{ kPa}}$$

$$P_{O_2} = y_{O_2} P_{\text{total}} = (0.21)(100 \text{ kPa}) = \mathbf{21 \text{ kPa}}$$

$$P_{Ar} = y_{Ar} P_{\text{total}} = (0.01)(100 \text{ kPa}) = \mathbf{1 \text{ kPa}}$$

<p>78% N_2 21% O_2 1% Ar (by volume)</p>
--

We consider 100 kmol of this mixture. Noting that volume fractions are equal to the mole fractions, mass of each component are

$$m_{N_2} = N_{N_2} M_{N_2} = (78 \text{ kmol})(28 \text{ kg/kmol}) = 2184 \text{ kg}$$

$$m_{O_2} = N_{O_2} M_{O_2} = (21 \text{ kmol})(32 \text{ kg/kmol}) = 672 \text{ kg}$$

$$m_{Ar} = N_{Ar} M_{Ar} = (1 \text{ kmol})(40 \text{ kg/kmol}) = 40 \text{ kg}$$

The total mass is

$$m_m = m_{N_2} + m_{O_2} + m_{Ar} = 2184 + 672 + 40 = 2896 \text{ kg}$$

Then the mass fractions are

$$\text{mf}_{N_2} = \frac{m_{N_2}}{m_m} = \frac{2184 \text{ kg}}{2896 \text{ kg}} = \mathbf{0.7541}$$

$$\text{mf}_{O_2} = \frac{m_{O_2}}{m_m} = \frac{672 \text{ kg}}{2896 \text{ kg}} = \mathbf{0.2320}$$

$$\text{mf}_{Ar} = \frac{m_{Ar}}{m_m} = \frac{40 \text{ kg}}{2896 \text{ kg}} = \mathbf{0.0138}$$

The apparent molecular weight of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{2896 \text{ kg}}{100 \text{ kmol}} = \mathbf{28.96 \text{ kg/kmol}}$$

The constant-pressure specific heat of the mixture is determined from

$$\begin{aligned} c_p &= \text{mf}_{N_2} c_{p,N_2} + \text{mf}_{O_2} c_{p,O_2} + \text{mf}_{Ar} c_{p,Ar} \\ &= 0.7541 \times 1.039 + 0.2320 \times 0.918 + 0.0138 \times 0.5203 \\ &= \mathbf{1.004 \text{ kJ/kg} \cdot \text{K}} \end{aligned}$$

The apparent gas constant of the mixture is

$$R = \frac{R_u}{M_m} = \frac{8.314 \text{ kJ/kmol} \cdot \text{K}}{28.96 \text{ kg/kmol}} = \mathbf{0.2871 \text{ kJ/kg} \cdot \text{K}}$$

This mixture closely correspond to the air, and the mixture properties determined (mixture molar mass, mixture gas constant and mixture specific heat) are practically the same as those listed for air in Tables A-1 and A-2a.

13-85 The mole numbers of combustion gases are given. The partial pressure of water vapor and the condensation temperature of water vapor are to be determined.

Properties The molar masses of CO_2 , H_2O , O_2 and N_2 are 44.0, 18.0, 32.0, and 28.0 kg/kmol, respectively (Table A-1).

Analysis The total mole of the mixture and the mole fraction of water vapor are

$$N_{\text{total}} = 8 + 9 + 4 + 94 = 115 \text{ kmol}$$

$$y_{\text{H}_2\text{O}} = \frac{N_{\text{H}_2\text{O}}}{N_{\text{total}}} = \frac{9}{115} = 0.07826$$

Noting that molar fraction is equal to pressure fraction, the partial pressure of water vapor is

$$P_{\text{H}_2\text{O}} = y_{\text{H}_2\text{O}} P_{\text{total}} = (0.07826)(101 \text{ kPa}) = \mathbf{7.90 \text{ kPa}}$$

The temperature at which the condensation starts is the saturation temperature of water at this pressure. This is called the dew-point temperature. Then,

$$T_{\text{cond}} = T_{\text{sat}@7.90 \text{ kPa}} = \mathbf{41.3^\circ\text{C}} \quad (\text{Table A-5})$$

Water vapor in the combustion gases will start to condense when the temperature of the combustion gases drop to 41.3°C .

13-86 Carbon dioxide and oxygen contained in one tank and nitrogen contained in another tank are allowed to mix during which heat is supplied to the gases. The final pressure and temperature of the mixture and the total volume of the mixture are to be determined.

Assumptions Under specified conditions CO_2 , N_2 , and O_2 can be treated as ideal gases, and the mixture as an ideal gas mixture.

Properties The molar masses of CO_2 , N_2 , and O_2 are 44.0, 28.0, and 32.0 kg/kmol, respectively (Table A-1). The gas constants of CO_2 , N_2 , and O_2 are 0.1889, 0.2968, 2598 kJ/kg.K, respectively (Table A-2).

Analysis The molar mass of the mixture in tank 1 are

$$M_m = y_{\text{CO}_2} M_{\text{CO}_2} + y_{\text{O}_2} M_{\text{O}_2} = (0.625)(44) + (0.375)(32) = 39.5 \text{ kg/kmol}$$

The gas constant in tank 1 is

$$R_1 = \frac{R_u}{M_m} = \frac{8.314 \text{ kJ/kmol.K}}{39.5 \text{ kg/kmol}} = 0.2104 \text{ kJ/kg.K}$$

The volumes of the tanks and the total volume are

$$V_1 = \frac{m_1 R_1 T_1}{P_1} = \frac{(5 \text{ kg})(0.2104 \text{ kJ/kg.K})(30 + 273 \text{ K})}{125 \text{ kPa}} = 2.551 \text{ m}^3$$

$$V_2 = \frac{m_2 R_2 T_2}{P_2} = \frac{(10 \text{ kg})(0.2968 \text{ kJ/kg.K})(15 + 273 \text{ K})}{200 \text{ kPa}} = 4.276 \text{ m}^3$$

$$V_{\text{total}} = V_1 + V_2 = 2.551 + 4.276 = \mathbf{6.828 \text{ m}^3}$$

The mass fractions in tank 1 are

$$\text{mf}_{\text{CO}_2,1} = y_{\text{CO}_2} \frac{M_{\text{CO}_2}}{M_m} = (0.625) \frac{44 \text{ kg/kmol}}{39.5 \text{ kg/kmol}} = 0.6963 \quad \text{mf}_{\text{O}_2,1} = y_{\text{O}_2} \frac{M_{\text{O}_2}}{M_m} = (0.375) \frac{32 \text{ kg/kmol}}{39.5 \text{ kg/kmol}} = 0.3037$$

The masses in tank 1 and the total mass after mixing are

$$m_{\text{CO}_2,1} = \text{mf}_{\text{CO}_2,1} m_1 = (0.6963)(5 \text{ kg}) = 3.481 \text{ kg}$$

$$m_{\text{O}_2,1} = \text{mf}_{\text{O}_2,1} m_1 = (0.3037)(5 \text{ kg}) = 1.519 \text{ kg}$$

$$m_{\text{total}} = m_1 + m_2 = 5 + 10 = 15 \text{ kg}$$

The mass fractions of the combined mixture are

$$\text{mf}_{\text{CO}_2,2} = \frac{m_{\text{CO}_2,1}}{m_{\text{total}}} = \frac{3.481}{15} = 0.2321 \quad \text{mf}_{\text{O}_2,2} = \frac{m_{\text{O}_2,1}}{m_{\text{total}}} = \frac{1.519}{15} = 0.1012 \quad \text{mf}_{\text{N}_2,2} = \frac{m_2}{m_{\text{total}}} = \frac{10}{15} = 0.6667$$

The initial internal energies are

$$T_1 = 30^\circ\text{C} \longrightarrow \begin{aligned} u_{\text{CO}_2,1} &= 2 - 8995 \text{ kJ/kg} \\ u_{\text{O}_2,1} &= -74.16 \text{ kJ/kg} \end{aligned} \quad T_2 = 15^\circ\text{C} \longrightarrow u_{\text{N}_2,1} = -84.77 \text{ kJ/kg}$$

Noting that there is no work interaction, an energy balance gives

$$Q_{\text{in}} = m_{\text{total}} \Delta u_m$$

$$Q_{\text{in}} / m_{\text{total}} = \text{mf}_{\text{CO}_2,2} (u_{\text{CO}_2,2} - u_{\text{CO}_2,1}) + \text{mf}_{\text{O}_2,2} (u_{\text{O}_2,2} - u_{\text{O}_2,1}) + \text{mf}_{\text{N}_2,2} (u_{\text{N}_2,2} - u_{\text{N}_2,1})$$

$$(100 \text{ kJ}) / (15 \text{ kg}) = (0.2321) [u_{\text{CO}_2,2} - (-8995)] + (0.1012) [u_{\text{O}_2,2} - (-74.16)] + (0.6667) [u_{\text{N}_2,2} - (-84.77)]$$

The internal energies after the mixing are a function of mixture temperature only. Using EES, the final temperature of the mixture is determined to be

$$T_{\text{mix}} = \mathbf{312.4 \text{ K}}$$

The gas constant of the final mixture is

$$R_{\text{mix}} = \text{mf}_{\text{CO}_2,2} R_{\text{CO}_2} + \text{mf}_{\text{O}_2,2} R_{\text{O}_2} + \text{mf}_{\text{N}_2,2} R_{\text{N}_2}$$

$$= (0.2321)(0.1889) + (0.1012)(0.2598) + (0.6667)(0.2968) = 0.2680 \text{ kJ/kg.K}$$

The final pressure is determined from ideal gas relation to be

$$P_{\text{mix}} = \frac{m_{\text{total}} R_{\text{mix}} T_{\text{mix}}}{V_{\text{total}}} = \frac{(15 \text{ kg})(0.2680 \text{ kJ/kg.K})(312.4 \text{ K})}{6.828 \text{ m}^3} = \mathbf{184 \text{ kPa}}$$

13-87 The volumetric fractions of the constituents of combustion gases are given. The mixture undergoes a reversible adiabatic expansion process in a piston-cylinder device. The work done is to be determined.

Assumptions Under specified conditions all CO_2 , H_2O , O_2 , and N_2 can be treated as ideal gases, and the mixture as an ideal gas mixture.

Properties The molar masses of CO_2 , H_2O , O_2 , and N_2 are 44.0, 18.0, 32.0, and 28.0 kg/kmol, respectively (Table A-1).

Analysis Noting that volume fractions are equal to mole fractions in ideal gas mixtures, the molar mass of the mixture is determined to be

$$\begin{aligned} M_m &= y_{\text{CO}_2} M_{\text{CO}_2} + y_{\text{H}_2\text{O}} M_{\text{H}_2\text{O}} + y_{\text{O}_2} M_{\text{O}_2} + y_{\text{N}_2} M_{\text{N}_2} \\ &= (0.0489)(44) + (0.0650)(18) + (0.1220)(32) + (0.7641)(28) = 28.63 \text{ kg/kmol} \end{aligned}$$

The mass fractions are

$$\text{mf}_{\text{CO}_2} = y_{\text{CO}_2} \frac{M_{\text{CO}_2}}{M_m} = (0.0489) \frac{44 \text{ kg/kmol}}{28.63 \text{ kg/kmol}} = 0.07516$$

$$\text{mf}_{\text{H}_2\text{O}} = y_{\text{H}_2\text{O}} \frac{M_{\text{H}_2\text{O}}}{M_m} = (0.0650) \frac{18 \text{ kg/kmol}}{28.63 \text{ kg/kmol}} = 0.0409$$

$$\text{mf}_{\text{O}_2} = y_{\text{O}_2} \frac{M_{\text{O}_2}}{M_m} = (0.1220) \frac{32 \text{ kg/kmol}}{28.63 \text{ kg/kmol}} = 0.1363$$

$$\text{mf}_{\text{N}_2} = y_{\text{N}_2} \frac{M_{\text{N}_2}}{M_m} = (0.7641) \frac{28 \text{ kg/kmol}}{28.63 \text{ kg/kmol}} = 0.7476$$

Using Dalton's law to find partial pressures, the entropies at the initial state are determined from EES to be:

$$T = 1800 \text{ K}, P = (0.0489 \times 1000) = 48.9 \text{ kPa} \longrightarrow s_{\text{CO}_2,1} = 7.0148 \text{ kJ/kg}\cdot\text{K}$$

$$T = 1800 \text{ K}, P = (0.0650 \times 1000) = 65 \text{ kPa} \longrightarrow s_{\text{H}_2\text{O},1} = 14.590 \text{ kJ/kg}\cdot\text{K}$$

$$T = 1800 \text{ K}, P = (0.1220 \times 1000) = 122 \text{ kPa} \longrightarrow s_{\text{N}_2,1} = 8.2570 \text{ kJ/kg}\cdot\text{K}$$

$$T = 1800 \text{ K}, P = (0.7641 \times 1000) = 764.1 \text{ kPa} \longrightarrow s_{\text{O}_2,1} = 8.2199 \text{ kJ/kg}\cdot\text{K}$$

The final state entropies cannot be determined at this point since the final temperature is not known. However, for an isentropic process, the entropy change is zero and the final temperature may be determined from

$$\Delta s_{\text{total}} = \text{mf}_{\text{CO}_2} \Delta s_{\text{CO}_2} + \text{mf}_{\text{H}_2\text{O}} \Delta s_{\text{H}_2\text{O}} + \text{mf}_{\text{O}_2} \Delta s_{\text{O}_2} + \text{mf}_{\text{N}_2} \Delta s_{\text{N}_2} = 0$$

The solution may be obtained using EES to be

$$T_2 = 1253 \text{ K}$$

The initial and final internal energies are (from EES)

$$\begin{array}{ll} T_1 = 1800 \text{ K} \longrightarrow & \begin{array}{l} u_{\text{CO}_2,1} = -7478 \text{ kJ/kg} \\ u_{\text{H}_2\text{O},1} = -10,779 \text{ kJ/kg} \\ u_{\text{O}_2,1} = 1147 \text{ kJ/kg} \\ u_{\text{N}_2,1} = 1214 \text{ kJ/kg} \end{array} & T_2 = 1253 \text{ K} \longrightarrow & \begin{array}{l} u_{\text{CO}_2,2} = -8102 \text{ kJ/kg} \\ u_{\text{H}_2\text{O},2} = -11,955 \text{ kJ/kg} \\ u_{\text{O}_2,2} = 662.8 \text{ kJ/kg} \\ u_{\text{N}_2,2} = 696.5 \text{ kJ/kg} \end{array} \end{array}$$

Noting that the heat transfer is zero, an energy balance on the system gives

$$q_{\text{in}} - w_{\text{out}} = \Delta u_m \longrightarrow w_{\text{out}} = -\Delta u_m$$

$$\text{where } \Delta u_m = \text{mf}_{\text{CO}_2} (u_{\text{CO}_2,2} - u_{\text{CO}_2,1}) + \text{mf}_{\text{H}_2\text{O}} (u_{\text{H}_2\text{O},2} - u_{\text{H}_2\text{O},1}) + \text{mf}_{\text{O}_2} (u_{\text{O}_2,2} - u_{\text{O}_2,1}) + \text{mf}_{\text{N}_2} (u_{\text{N}_2,2} - u_{\text{N}_2,1})$$

Substituting,

$$\begin{aligned} w_{\text{out}} = -\Delta u_m &= -0.07516[(-8102) - (-7478)] - 0.0409[(-11,955) - (-10,779)] \\ &\quad - 0.1363[662.8 - 1147] - 0.7476[696.5 - 1214] \\ &= \mathbf{547.8 \text{ kJ/kg}} \end{aligned}$$

13-88 The masses of gases forming a mixture at a specified pressure and temperature are given. The mass of the gas mixture is to be determined using four methods.

Properties The molar masses of O₂, CO₂, and He are 32.0, 44.0, and 4.0 kg/kmol, respectively (Table A-1).

Analysis (a) The given total mass of the mixture is

$$m_m = m_{\text{O}_2} + m_{\text{CO}_2} + m_{\text{He}} = 0.1 + 1 + 0.5 = 1.6 \text{ kg}$$

The mole numbers of each component are

$$N_{\text{O}_2} = \frac{m_{\text{O}_2}}{M_{\text{O}_2}} = \frac{0.1 \text{ kg}}{32 \text{ kg/kmol}} = 0.003125 \text{ kmol}$$

$$N_{\text{CO}_2} = \frac{m_{\text{CO}_2}}{M_{\text{CO}_2}} = \frac{1 \text{ kg}}{44 \text{ kg/kmol}} = 0.02273 \text{ kmol}$$

$$N_{\text{He}} = \frac{m_{\text{He}}}{M_{\text{He}}} = \frac{0.5 \text{ kg}}{4 \text{ kg/kmol}} = 0.125 \text{ kmol}$$

0.1 kg O ₂
1 kg CO ₂
0.5 kg He

The mole number of the mixture is

$$N_m = N_{\text{O}_2} + N_{\text{CO}_2} + N_{\text{He}} = 0.003125 + 0.02273 + 0.125 = 0.1509 \text{ kmol}$$

Then the apparent molecular weight of the mixture becomes

$$M_m = \frac{m_m}{N_m} = \frac{1.6 \text{ kg}}{0.1509 \text{ kmol}} = 10.61 \text{ kg/kmol}$$

The mass of this mixture in a 0.3 m³ tank is

$$m = \frac{M_m P V}{R_u T} = \frac{(10.61 \text{ kg/kmol})(17,500 \text{ kPa})(0.3 \text{ m}^3)}{(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(293 \text{ K})} = \mathbf{22.87 \text{ kg}}$$

(b) To use the Amagat's law for this real gas mixture, we first need the mole fractions and the *Z* of each component at the mixture temperature and pressure.

$$y_{\text{O}_2} = \frac{N_{\text{O}_2}}{N_m} = \frac{0.003125 \text{ kmol}}{0.1509 \text{ kmol}} = 0.02071$$

$$y_{\text{CO}_2} = \frac{N_{\text{CO}_2}}{N_m} = \frac{0.02273 \text{ kmol}}{0.1509 \text{ kmol}} = 0.1506$$

$$y_{\text{He}} = \frac{N_{\text{He}}}{N_m} = \frac{0.125 \text{ kmol}}{0.1509 \text{ kmol}} = 0.8284$$

$$\left. \begin{aligned} T_{R,\text{O}_2} &= \frac{T_m}{T_{\text{cr},\text{O}_2}} = \frac{293 \text{ K}}{154.8 \text{ K}} = 1.893 \\ P_{R,\text{O}_2} &= \frac{P_m}{P_{\text{cr},\text{O}_2}} = \frac{17.5 \text{ MPa}}{5.08 \text{ MPa}} = 3.445 \end{aligned} \right\} Z_{\text{O}_2} = 0.93 \quad (\text{Fig. A-15})$$

$$\left. \begin{aligned} T_{R,\text{CO}_2} &= \frac{T_m}{T_{\text{cr},\text{CO}_2}} = \frac{293 \text{ K}}{304.2 \text{ K}} = 0.963 \\ P_{R,\text{CO}_2} &= \frac{P_m}{P_{\text{cr},\text{CO}_2}} = \frac{17.5 \text{ MPa}}{7.39 \text{ MPa}} = 2.368 \end{aligned} \right\} Z_{\text{CO}_2} = 0.33 \quad (\text{Fig. A-15})$$

$$\left. \begin{aligned} T_{R,\text{He}} &= \frac{T_m}{T_{\text{cr},\text{He}}} = \frac{293 \text{ K}}{5.3 \text{ K}} = 55.3 \\ P_{R,\text{He}} &= \frac{P_m}{P_{\text{cr},\text{He}}} = \frac{17.5 \text{ MPa}}{0.23 \text{ MPa}} = 76.1 \end{aligned} \right\} Z_{\text{He}} = 1.04 \quad (\text{from EES})$$

Then,

$$Z_m = \sum y_i Z_i = y_{O_2} Z_{O_2} + y_{CO_2} Z_{CO_2} + y_{He} Z_{He}$$

$$= (0.02071)(0.93) + (0.1506)(0.33) + (0.8284)(1.04) = 0.9305$$

$$m = \frac{M_m P V}{Z_m R_u T} = \frac{(10.61 \text{ kg/kmol})(17,500 \text{ kPa})(0.3 \text{ m}^3)}{(0.9305)(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(293 \text{ K})} = \mathbf{24.57 \text{ kg}}$$

(c) To use Dalton's law with compressibility factors:

$$\left. \begin{aligned} T_{R,O_2} &= 1.893 \\ \nu_{R,O_2} &= \frac{\nu_m/m_{O_2}}{R_{O_2} T_{cr,O_2} / P_{cr,O_2}} = \frac{(0.3 \text{ m}^3)/(22.87 \times 0.1/1.6 \text{ kg})}{(0.2598 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(154.8 \text{ K})/(5080 \text{ kPa})} = 26.5 \end{aligned} \right\} Z_{O_2} = 1.0$$

$$\left. \begin{aligned} T_{R,CO_2} &= 0.963 \\ \nu_{R,CO_2} &= \frac{\nu_m/m_{CO_2}}{R_{CO_2} T_{cr,CO_2} / P_{cr,CO_2}} = \frac{(0.3 \text{ m}^3)/(22.87 \times 1.0/1.6 \text{ kg})}{(0.1889 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(304.2 \text{ K})/(7390 \text{ kPa})} = 2.70 \end{aligned} \right\} Z_{CO_2} = 0.86$$

$$\left. \begin{aligned} T_{R,He} &= 55.3 \\ \nu_{R,He} &= \frac{\nu_m/m_{He}}{R_{He} T_{cr,He} / P_{cr,He}} = \frac{(0.3 \text{ m}^3)/(22.87 \times 0.5/1.6 \text{ kg})}{(2.0769 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(5.3 \text{ K})/(230 \text{ kPa})} = 0.88 \end{aligned} \right\} Z_{He} = 1.0$$

Note that we used $m = 22.87 \text{ kg}$ in above calculations, the value obtained by ideal gas behavior. The solution normally requires iteration until the assumed and calculated mass values match. The mass of the component gas is obtained by multiplying the mass of the mixture by its mass fraction. Then,

$$Z_m = \sum y_i Z_i = y_{O_2} Z_{O_2} + y_{CO_2} Z_{CO_2} + y_{He} Z_{He}$$

$$= (0.02071)(1.0) + (0.1506)(0.86) + (0.8284)(1.0) = 0.9786$$

$$m = \frac{M_m P V}{Z_m R_u T} = \frac{(10.61 \text{ kg/kmol})(17,500 \text{ kPa})(0.3 \text{ m}^3)}{(0.9786)(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(293 \text{ K})} = \mathbf{23.37 \text{ kg}}$$

This mass is sufficiently close to the mass value 22.87 kg. Therefore, there is no need to repeat the calculations at this calculated mass.

(d) To use Kay's rule, we need to determine the pseudo-critical temperature and pseudo-critical pressure of the mixture using the critical point properties of O_2 , CO_2 and He.

$$T'_{cr,m} = \sum y_i T_{cr,i} = y_{O_2} T_{cr,O_2} + y_{CO_2} T_{cr,CO_2} + y_{He} T_{cr,He}$$

$$= (0.02071)(154.8 \text{ K}) + (0.1506)(304.2 \text{ K}) + (0.8284)(5.3 \text{ K}) = 53.41 \text{ K}$$

$$P'_{cr,m} = \sum y_i P_{cr,i} = y_{O_2} P_{cr,O_2} + y_{CO_2} P_{cr,CO_2} + y_{He} P_{cr,He}$$

$$= (0.02071)(5.08 \text{ MPa}) + (0.1506)(7.39 \text{ MPa}) + (0.8284)(0.23 \text{ MPa}) = 1.409 \text{ MPa}$$

Then,

$$\left. \begin{aligned} T_R &= \frac{T_m}{T'_{cr,m}} = \frac{293 \text{ K}}{53.41 \text{ K}} = 5.486 \\ P_R &= \frac{P_m}{P'_{cr,m}} = \frac{17.5 \text{ MPa}}{1.409 \text{ MPa}} = 12.42 \end{aligned} \right\} Z_m = 1.194 \quad (\text{from EES})$$

$$m = \frac{M_m P V}{Z_m R_u T} = \frac{(10.61 \text{ kg/kmol})(17,500 \text{ kPa})(0.3 \text{ m}^3)}{(1.194)(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(293 \text{ K})} = \mathbf{19.15 \text{ kg}}$$

13-89 A gas mixture is heated during a steady-flow process. The heat transfer is to be determined using two approaches.

Assumptions 1 Steady flow conditions exist. **2** Kinetic and potential energy changes are negligible.

Analysis Noting that there is no work involved, the energy balance for this gas mixture can be written, on a unit mole basis, as

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\text{no (steady)}}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\bar{q}_{\text{in}} + \bar{h}_1 = \bar{h}_2$$

$$\bar{q}_{\text{in}} = \Delta \bar{h}$$

Also,

$$y_{\text{O}_2} = 0.25 \quad \text{and} \quad y_{\text{N}_2} = 0.75.$$

(a) Assuming ideal gas behavior, the inlet and exit enthalpies of O_2 and N_2 are determined from the ideal gas tables to be

$$\text{O}_2 : h_1 = h_{@180\text{K}} = 5239.6 \text{ kJ/kmol}, \quad h_2 = h_{@210\text{K}} = 6112.9 \text{ kJ/kmol}$$

$$\text{N}_2 : h_1 = h_{@180\text{K}} = 5229 \text{ kJ/kmol}, \quad h_2 = h_{@210\text{K}} = 6,100.5 \text{ kJ/kmol}$$

Thus,

$$\begin{aligned} \bar{q}_{\text{in,ideal}} &= \sum y_i \Delta \bar{h}_i = y_{\text{O}_2} (\bar{h}_2 - \bar{h}_1)_{\text{O}_2} + y_{\text{N}_2} (\bar{h}_2 - \bar{h}_1)_{\text{N}_2} \\ &= (0.25)(6,112.9 - 5,239.6) + (0.75)(6,100.5 - 5,229) \\ &= \mathbf{872.0 \text{ kJ/kmol}} \end{aligned}$$

(b) Using the Kay's rule, the gas mixture can be treated as a pseudo-pure substance whose critical temperature and pressure are

$$\begin{aligned} T'_{\text{cr,m}} &= \sum y_i T_{\text{cr},i} = y_{\text{O}_2} T_{\text{cr,O}_2} + y_{\text{N}_2} T_{\text{cr,N}_2} \\ &= (0.25)(154.8 \text{ K}) + (0.75)(126.2 \text{ K}) \\ &= 133.4 \text{ K} \end{aligned}$$

$$\begin{aligned} P'_{\text{cr,m}} &= \sum y_i P_{\text{cr},i} = y_{\text{O}_2} P_{\text{cr,O}_2} + y_{\text{N}_2} P_{\text{cr,N}_2} \\ &= (0.25)(5.08 \text{ MPa}) + (0.75)(3.39 \text{ MPa}) \\ &= 3.81 \text{ MPa} \end{aligned}$$

Then,

$$\left. \begin{aligned} T_{R,1} &= \frac{T_{m,1}}{T_{\text{cr,m}}} = \frac{180}{133.4} = 1.349 \\ P_{R,1} &= P_{R,2} = \frac{P_m}{P_{\text{cr,m}}} = \frac{8}{3.81} = 2.100 \\ T_{R,2} &= \frac{T_{m,2}}{T_{\text{cr,m}}} = \frac{210}{133.4} = 1.574 \end{aligned} \right\} \begin{aligned} Z_{h_1} &= 1.4 \\ Z_{h_2} &= 1.1 \end{aligned} \quad (\text{Fig. A-29})$$

The heat transfer in this case is determined from

$$\begin{aligned} \bar{q}_{\text{in}} &= \bar{h}_2 - \bar{h}_1 = R_u T_{\text{cr}} (Z_{h_1} - Z_{h_2}) + (\bar{h}_2 - \bar{h}_1)_{\text{ideal}} \\ &= R_u T_{\text{cr}} (Z_{h_1} - Z_{h_2}) + \bar{q}_{\text{ideal}} \\ &= (8.314 \text{ kJ/kmol} \cdot \text{K})(133.4 \text{ K})(1.4 - 1.1) + (872 \text{ kJ/kmol}) \\ &= \mathbf{1205 \text{ kJ/kmol}} \end{aligned}$$

13-90 Problem 13-89 is reconsidered. The effect of the mole fraction of oxygen in the mixture on heat transfer using real gas behavior with EES data is to be investigated.

Analysis The problem is solved using EES, and the solution is given below.

"Input Data:"

$y_{N_2}/y_{O_2} = 3$

$T[1] = 180$ [K] "Inlet temperature"

$T[2] = 210$ [K] "Exit temperature"

$P = 8000$ [kPa]

$R_u = 8.34$ [kJ/kmol-K]

"Solution is done on a unit mole of mixture basis:"

$y_{N_2} + y_{O_2} = 1$

$\Delta e_{bar_sys} = 0$ "Steady-flow analysis for all cases"

"Ideal gas:"

$e_{bar_in_IG} - e_{bar_out_IG} = \Delta e_{bar_sys}$

$e_{bar_in_IG} = q_{bar_in_IG} + h_{bar_1_IG}$

$e_{bar_out_IG} = h_{bar_2_IG}$

$h_{bar_1_IG} = y_{N_2} \cdot \text{enthalpy}(N_2, T=T[1]) + y_{O_2} \cdot \text{enthalpy}(O_2, T=T[1])$

$h_{bar_2_IG} = y_{N_2} \cdot \text{enthalpy}(N_2, T=T[2]) + y_{O_2} \cdot \text{enthalpy}(O_2, T=T[2])$

"EES:"

$P_{N_2} = y_{N_2} \cdot P$

$P_{O_2} = y_{O_2} \cdot P$

$e_{bar_in_EES} - e_{bar_out_EES} = \Delta e_{bar_sys}$

$e_{bar_in_EES} = q_{bar_in_EES} + h_{bar_1_EES}$

$e_{bar_out_EES} = h_{bar_2_EES}$

$h_{bar_1_EES} = y_{N_2} \cdot \text{enthalpy}(\text{Nitrogen}, T=T[1], P=P_{N_2}) + y_{O_2} \cdot \text{enthalpy}(\text{Oxygen}, T=T[1], P=P_{O_2})$

$h_{bar_2_EES} = y_{N_2} \cdot \text{enthalpy}(\text{Nitrogen}, T=T[2], P=P_{N_2}) + y_{O_2} \cdot \text{enthalpy}(\text{Oxygen}, T=T[2], P=P_{O_2})$

"Kay's Rule:"

$T_{cr_N_2} = 126.2$ [K] "Table A.1"

$T_{cr_O_2} = 154.8$ [K]

$P_{cr_N_2} = 3390$ [kPa] "Table A.1"

$P_{cr_O_2} = 5080$ [kPa]

$T_{cr_mix} = y_{N_2} \cdot T_{cr_N_2} + y_{O_2} \cdot T_{cr_O_2}$

$P_{cr_mix} = y_{N_2} \cdot P_{cr_N_2} + y_{O_2} \cdot P_{cr_O_2}$

$e_{bar_in_Zchart} - e_{bar_out_Zchart} = \Delta e_{bar_sys}$

1722	1026	1892	0.99

13-91 A gas mixture is heated during a steady-flow process, as discussed in the previous problem. The total entropy change and the exergy destruction are to be determined using two methods.

Analysis The entropy generated during this process is determined by applying the entropy balance on an *extended system* that includes the piston-cylinder device and its immediate surroundings so that the boundary temperature of the extended system is the environment temperature at all times. It gives

$$S_{\text{in}} - S_{\text{out}} + S_{\text{gen}} = \Delta S_{\text{system}}$$

$$\frac{Q_{\text{in}}}{T_{\text{boundary}}} + S_{\text{gen}} = \Delta S_{\text{system}} \rightarrow S_{\text{gen}} = m(s_2 - s_1) - \frac{Q_{\text{in}}}{T_{\text{surr}}}$$

Then the exergy destroyed during a process can be determined from its definition $X_{\text{destroyed}} = T_0 S_{\text{gen}}$.

(a) Noting that the total mixture pressure, and thus the partial pressure of each gas, remains constant, the entropy change of a component in the mixture during this process is

$$\Delta \bar{s}_i = \left(\bar{c}_p \ln \frac{T_2}{T_1} - R_u \ln \frac{P_2}{P_1} \right)_i = M c_p \ln \frac{T_2}{T_1}$$

Assuming ideal gas behavior and c_p values at room temperature (Table A-2), the $\Delta \bar{s}$ of O_2 and N_2 are determined from

$$\Delta \bar{s}_{O_2, \text{ideal}} = (32 \text{ kg/kmol})(0.918 \text{ kJ/kg} \cdot \text{K}) \ln \frac{210 \text{ K}}{180 \text{ K}} = 4.52 \text{ kJ/kmol} \cdot \text{K}$$

$$\Delta \bar{s}_{N_2, \text{ideal}} = (28 \text{ kg/kmol})(1.039 \text{ kJ/kg} \cdot \text{K}) \ln \frac{210 \text{ K}}{180 \text{ K}} = 4.48 \text{ kJ/kmol} \cdot \text{K}$$

$$\begin{aligned} \Delta \bar{s}_{\text{sys ideal}} &= \sum y_i \Delta \bar{s}_i = y_{O_2} \Delta \bar{s}_{O_2} + y_{N_2} \Delta \bar{s}_{N_2} \\ &= (0.25)(4.52 \text{ kJ/kmol} \cdot \text{K}) + (0.75)(4.48 \text{ kJ/kmol} \cdot \text{K}) \\ &= 4.49 \text{ kJ/kmol} \cdot \text{K} \end{aligned}$$

and

$$\bar{s}_{\text{gen}} = 4.49 \text{ kJ/kmol} \cdot \text{K} - \frac{872 \text{ kJ/kmol}}{303 \text{ K}} = \mathbf{1.61 \text{ kJ/kmol} \cdot \text{K}}$$

$$\bar{x}_{\text{destroyed}} = T_0 \bar{s}_{\text{gen}} = (303 \text{ K})(1.61 \text{ kJ/kmol} \cdot \text{K}) = \mathbf{488 \text{ kJ/kmol}}$$

(b) Using the Kay's rule, the gas mixture can be treated as a pseudo-pure substance whose critical temperature and pressure are

$$\begin{aligned} T'_{\text{cr}, m} &= \sum y_i T_{\text{cr}, i} = y_{O_2} T_{\text{cr}, O_2} + y_{N_2} T_{\text{cr}, N_2} \\ &= (0.25)(154.8 \text{ K}) + (0.75)(126.2 \text{ K}) \\ &= 133.4 \text{ K} \end{aligned}$$

$$\begin{aligned} P'_{\text{cr}, m} &= \sum y_i P_{\text{cr}, i} = y_{O_2} P_{\text{cr}, O_2} + y_{N_2} P_{\text{cr}, N_2} \\ &= (0.25)(5.08 \text{ MPa}) + (0.75)(3.39 \text{ MPa}) \\ &= 3.81 \text{ MPa} \end{aligned}$$

Then,

$$\left. \begin{aligned} T_{R,1} &= \frac{T_{m,1}}{T_{cr,m}} = \frac{180}{133.4} = 1.349 \\ P_{R,1} &= P_{R,2} = \frac{P_m}{P_{cr,m}} = \frac{8}{3.81} = 2.100 \\ T_{R,2} &= \frac{T_{m,2}}{T_{cr,m}} = \frac{210}{133.4} = 1.574 \end{aligned} \right\} \begin{aligned} Z_{s_1} &= 0.8 \\ Z_{s_2} &= 0.45 \end{aligned} \quad (\text{Fig. A-30})$$

Thus,

$$\begin{aligned} \Delta \bar{s}_{\text{sys}} &= R_u (Z_{s_1} - Z_{s_2}) + \Delta \bar{s}_{\text{sys ideal}} \\ &= (8.314 \text{ kJ/kmol} \cdot \text{K})(0.8 - 0.45) + (4.49 \text{ kJ/kmol} \cdot \text{K}) \\ &= 7.40 \text{ kJ/kmol} \cdot \text{K} \end{aligned}$$

and

$$\begin{aligned} \bar{s}_{gen} &= 7.40 \text{ kJ/kmol} \cdot \text{K} - \frac{1204.7 \text{ kJ/kmol}}{303 \text{ K}} = \mathbf{3.41 \text{ kJ/kmol} \cdot \text{K}} \\ \bar{x}_{\text{destroyed}} &= T_0 \bar{s}_{gen} = (303 \text{ K})(3.41 \text{ kJ/kmol} \cdot \text{K}) = \mathbf{1034 \text{ kJ/kmol}} \end{aligned}$$

13-92 The specific heat ratio and an apparent molecular weight of a mixture of ideal gases are given. The work required to compress this mixture isentropically in a closed system is to be determined.

Analysis For an isentropic process of an ideal gas with constant specific heats, the work is expressed as

$$w_{\text{out}} = \int_1^2 P d\nu = P_1 \nu_1^k \int_1^2 \nu^{-k} d\nu$$

$$= \frac{P_1 \nu_1^k}{1-k} (\nu_2^{1-k} - \nu_1^{1-k}) = \frac{P_1 \nu_1^k}{1-k} \left[\left(\frac{\nu_2}{\nu_1} \right)^{1-k} - 1 \right]$$

since $P_1 \nu_1^k = P \nu^k$ for an isentropic process. Also,

$$P_1 \nu_1 = RT_1$$

$$(\nu_2 / \nu_1)^k = P_1 / P_2$$

Substituting, we obtain

$$w_{\text{out}} = \frac{R_u T_1}{M(1-k)} \left[\left(\frac{P_2}{P_1} \right)^{(k-1)/k} - 1 \right]$$

$$= \frac{(8.314 \text{ kJ/kmol} \cdot \text{K})(288 \text{ K})}{(32 \text{ kg/kmol})(1-1.35)} \left[\left(\frac{700 \text{ kPa}}{100 \text{ kPa}} \right)^{(1.35-1)/1.35} - 1 \right]$$

$$= \mathbf{-140 \text{ kJ/kg}}$$

The negative sign shows that the work is done on the system.

13-93 A mixture of gases is placed in a spring-loaded piston-cylinder device. The device is now heated until the pressure rises to a specified value. The total work and heat transfer for this process are to be determined.

Properties The molar masses of Ne, O₂, and N₂ are 20.18, 32.0, 28.0 kg/kmol, respectively and the gas constants are 0.4119, 0.2598, and 0.2968 kJ/kg·K, respectively (Table A-1). The constant-volume specific heats are 0.6179, 0.658, and 0.743 kJ/kg·K, respectively (Table A-2a).

Analysis The total pressure is 200 kPa and the partial pressures are

$$P_{\text{Ne}} = y_{\text{Ne}} P_m = (0.25)(200 \text{ kPa}) = 50 \text{ kPa}$$

$$P_{\text{O}_2} = y_{\text{O}_2} P_m = (0.50)(200 \text{ kPa}) = 100 \text{ kPa}$$

$$P_{\text{N}_2} = y_{\text{N}_2} P_m = (0.25)(200 \text{ kPa}) = 50 \text{ kPa}$$

The mass of each constituent for a volume of 0.1 m³ and a temperature of 10°C are

$$m_{\text{Ne}} = \frac{P_{\text{Ne}} V_m}{R_{\text{Ne}} T} = \frac{(50 \text{ kPa})(0.1 \text{ m}^3)}{(0.4119 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(283 \text{ K})} = 0.04289 \text{ kg}$$

$$m_{\text{O}_2} = \frac{P_{\text{O}_2} V_m}{R_{\text{O}_2} T} = \frac{(100 \text{ kPa})(0.1 \text{ m}^3)}{(0.2598 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(283 \text{ K})} = 0.1360 \text{ kg}$$

$$m_{\text{N}_2} = \frac{P_{\text{N}_2} V_m}{R_{\text{N}_2} T} = \frac{(50 \text{ kPa})(0.1 \text{ m}^3)}{(0.2968 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(283 \text{ K})} = 0.05953 \text{ kg}$$

$$m_{\text{total}} = 0.04289 + 0.1360 + 0.05953 = 0.2384 \text{ kg}$$

The mass fractions are

$$\text{mf}_{\text{Ne}} = \frac{m_{\text{Ne}}}{m_m} = \frac{0.04289 \text{ kg}}{0.2384 \text{ kg}} = 0.1799$$

$$\text{mf}_{\text{O}_2} = \frac{m_{\text{O}_2}}{m_m} = \frac{0.1360 \text{ kg}}{0.2384 \text{ kg}} = 0.5705$$

$$\text{mf}_{\text{N}_2} = \frac{m_{\text{N}_2}}{m_m} = \frac{0.05953 \text{ kg}}{0.2384 \text{ kg}} = 0.2497$$

The constant-volume specific heat of the mixture is determined from

$$\begin{aligned} c_v &= \text{mf}_{\text{Ne}} c_{v,\text{Ne}} + \text{mf}_{\text{O}_2} c_{v,\text{O}_2} + \text{mf}_{\text{N}_2} c_{v,\text{N}_2} \\ &= 0.1799 \times 0.6179 + 0.5705 \times 0.658 + 0.2497 \times 0.743 \\ &= 0.672 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

The moles are

$$N_{\text{Ne}} = \frac{m_{\text{Ne}}}{M_{\text{Ne}}} = \frac{0.04289 \text{ kg}}{20.18 \text{ kg/kmol}} = 0.002126 \text{ kmol}$$

$$N_{\text{O}_2} = \frac{m_{\text{O}_2}}{M_{\text{O}_2}} = \frac{0.1360 \text{ kg}}{32 \text{ kg/kmol}} = 0.00425 \text{ kmol}$$

$$N_{\text{N}_2} = \frac{m_{\text{N}_2}}{M_{\text{N}_2}} = \frac{0.05953 \text{ kg}}{28 \text{ kg/kmol}} = 0.002126 \text{ kmol}$$

$$N_m = N_{\text{Ne}} + N_{\text{O}_2} + N_{\text{N}_2} = 0.008502 \text{ kmol}$$

Then the apparent molecular weight of the mixture becomes

$$M_m = \frac{m_m}{N_m} = \frac{0.2384 \text{ kg}}{0.008502 \text{ kmol}} = 28.04 \text{ kg/kmol}$$

The apparent gas constant of the mixture is

$$R = \frac{R_u}{M_m} = \frac{8.314 \text{ kJ/kmol} \cdot \text{K}}{28.05 \text{ kg/kmol}} = 0.2964 \text{ kJ/kg} \cdot \text{K}$$

The mass contained in the system is

$$m = \frac{P_1 \mathcal{V}_1}{RT_1} = \frac{(200 \text{ kPa})(0.1 \text{ m}^3)}{(0.2964 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(283 \text{ K})} = 0.2384 \text{ kg}$$

Noting that the pressure changes linearly with volume, the final volume is determined by linear interpolation to be

$$\frac{500 - 200}{1000 - 200} = \frac{\mathcal{V}_2 - 0.1}{1.0 - 0.1} \longrightarrow \mathcal{V}_2 = 0.4375 \text{ m}^3$$

The final temperature is

$$T_2 = \frac{P_2 \mathcal{V}_2}{mR} = \frac{(500 \text{ kPa})(0.4375 \text{ m}^3)}{(0.2384 \text{ kg})(0.2964 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})} = 3096 \text{ K}$$

The work done during this process is

$$W_{\text{out}} = \frac{P_1 + P_2}{2} (\mathcal{V}_2 - \mathcal{V}_1) = \frac{(500 + 200) \text{ kPa}}{2} (0.4375 - 0.1) \text{ m}^3 = \mathbf{118 \text{ kJ}}$$

An energy balance on the system gives

$$Q_{\text{in}} = W_{\text{out}} + mc_v(T_2 - T_1) = 118 + (0.2384 \text{ kg})(0.672 \text{ kJ/kg} \cdot \text{K})(3096 - 283) \text{ K} = \mathbf{569 \text{ kJ}}$$

13-94 A spring-loaded piston-cylinder device is filled with a mixture of nitrogen and carbon dioxide whose mass fractions are given. The gas is heated until the volume has doubled. The total work and heat transfer for this process are to be determined.

Properties The molar masses of N_2 and CO_2 are 28.0 and 44.0 kg/kmol, respectively (Table A-1). The constant-volume specific heats of these gases at room temperature are 0.743 and 0.657 kJ/kg·K, respectively (Table A-2a).

Analysis We consider 100 kg of this mixture. The mole numbers of each component are

$$N_{N_2} = \frac{m_{N_2}}{M_{N_2}} = \frac{55 \text{ kg}}{28 \text{ kg/kmol}} = 1.964 \text{ kmol}$$

$$N_{CO_2} = \frac{m_{CO_2}}{M_{CO_2}} = \frac{45 \text{ kg}}{44 \text{ kg/kmol}} = 1.023 \text{ kmol}$$

The mole number of the mixture is

$$N_m = N_{N_2} + N_{CO_2} = 1.964 + 1.023 = 2.987 \text{ kmol}$$

The apparent molecular weight of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{100 \text{ kg}}{2.987 \text{ kmol}} = 33.48 \text{ kg/kmol}$$

The constant-volume specific heat of the mixture is determined from

$$c_v = mf_{N_2}c_{v,N_2} + mf_{CO_2}c_{v,CO_2} = 0.55 \times 0.743 + 0.45 \times 0.657 = 0.7043 \text{ kJ/kg} \cdot \text{K}$$

The apparent gas constant of the mixture is

$$R = \frac{R_u}{M_m} = \frac{8.134 \text{ kJ/kmol} \cdot \text{K}}{33.48 \text{ kg/kmol}} = 0.2483 \text{ kJ/kg} \cdot \text{K}$$

Noting that the pressure changes linearly with volume, the initial volume is determined by linear interpolation using the data of the previous problem to be

$$\frac{200 - 200}{1000 - 200} = \frac{V_1 - 0.1}{1.0 - 0.1} \longrightarrow V_1 = 0.1 \text{ m}^3$$

The final volume is

$$V_2 = 2V_1 = 2(0.1 \text{ m}^3) = 0.2 \text{ m}^3$$

The final pressure is similarly determined by linear interpolation using the data of the previous problem to be

$$\frac{P_2 - 200}{1000 - 200} = \frac{0.2 - 0.1}{1.0 - 0.1} \longrightarrow P_2 = 288.9 \text{ kPa}$$

The mass contained in the system is

$$m = \frac{P_1 V_1}{RT_1} = \frac{(200 \text{ kPa})(0.1 \text{ m}^3)}{(0.2483 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(318 \text{ K})} = 0.2533 \text{ kg}$$

The final temperature is

$$T_2 = \frac{P_2 V_2}{mR} = \frac{(288.9 \text{ kPa})(0.2 \text{ m}^3)}{(0.2533 \text{ kg})(0.2483 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})} = 918.7 \text{ K}$$

The work done during this process is

$$W_{\text{out}} = \frac{P_1 + P_2}{2} (V_2 - V_1) = \frac{(200 + 288.9) \text{ kPa}}{2} (0.2 - 0.1) \text{ m}^3 = \mathbf{24.4 \text{ kJ}}$$

An energy balance on the system gives

$$Q_{\text{in}} = W_{\text{out}} + mc_v(T_2 - T_1) = 24.4 + (0.2533 \text{ kg})(0.7043 \text{ kJ/kg} \cdot \text{K})(918.7 - 318) \text{ K} = \mathbf{132 \text{ kJ}}$$

13-95 A spring-loaded piston-cylinder device is filled with a mixture of nitrogen and carbon dioxide whose mass fractions are given. The gas is heated until the pressure has tripled. The total work and heat transfer for this process are to be determined.

Properties The molar masses of N_2 and CO_2 are 28.0 and 44.0 kg/kmol, respectively (Table A-1). The constant-volume specific heats of these gases at room temperature are 0.743 and 0.657 kJ/kg·K, respectively (Table A-2a).

Analysis We consider 100 kg of this mixture. The mole numbers of each component are

$$N_{N_2} = \frac{m_{N_2}}{M_{N_2}} = \frac{55 \text{ kg}}{28 \text{ kg/kmol}} = 1.964 \text{ kmol}$$

$$N_{CO_2} = \frac{m_{CO_2}}{M_{CO_2}} = \frac{45 \text{ kg}}{44 \text{ kg/kmol}} = 1.023 \text{ kmol}$$

The mole number of the mixture is

$$N_m = N_{N_2} + N_{CO_2} = 1.964 + 1.023 = 2.987 \text{ kmol}$$

The apparent molecular weight of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{100 \text{ kg}}{2.987 \text{ kmol}} = 33.48 \text{ kg/kmol}$$

The constant-volume specific heat of the mixture is determined from

$$c_v = mf_{N_2}c_{v,N_2} + mf_{CO_2}c_{v,CO_2} = 0.55 \times 0.743 + 0.45 \times 0.657 = 0.7043 \text{ kJ/kg} \cdot \text{K}$$

The apparent gas constant of the mixture is

$$R = \frac{R_u}{M_m} = \frac{8.134 \text{ kJ/kmol} \cdot \text{K}}{33.48 \text{ kg/kmol}} = 0.2483 \text{ kJ/kg} \cdot \text{K}$$

Noting that the pressure changes linearly with volume, the initial volume is determined by linear interpolation using the data of the previous problem to be

$$\frac{200 - 200}{1000 - 200} = \frac{V_1 - 0.1}{1.0 - 0.1} \rightarrow V_1 = 0.1 \text{ m}^3$$

The final pressure is

$$P_2 = 3P_1 = 3(200 \text{ kPa}) = 600 \text{ kPa}$$

The final volume is similarly determined by linear interpolation using the data of the previous problem to be

$$\frac{600 - 200}{1000 - 200} = \frac{V_2 - 0.1}{1.0 - 0.1} \rightarrow V_2 = 0.55 \text{ m}^3$$

The mass contained in the system is

$$m = \frac{P_1 V_1}{RT_1} = \frac{(200 \text{ kPa})(0.1 \text{ m}^3)}{(0.2483 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(318 \text{ K})} = 0.2533 \text{ kg}$$

The final temperature is

$$T_2 = \frac{P_2 V_2}{mR} = \frac{(600 \text{ kPa})(0.55 \text{ m}^3)}{(0.2533 \text{ kg})(0.2483 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})} = 5247 \text{ K}$$

The work done during this process is

$$W_{\text{out}} = \frac{P_1 + P_2}{2} (V_2 - V_1) = \frac{(200 + 600) \text{ kPa}}{2} (0.55 - 0.1) \text{ m}^3 = \mathbf{180 \text{ kJ}}$$

An energy balance on the system gives

$$Q_{\text{in}} = W_{\text{out}} + mc_v(T_2 - T_1) = 180 + (0.2533 \text{ kg})(0.7043 \text{ kJ/kg} \cdot \text{K})(5247 - 318) \text{ K} = \mathbf{1059 \text{ kJ}}$$

13-96 The masses, pressures, and temperatures of the constituents of a gas mixture in a tank are given. Heat is transferred to the tank. The final pressure of the mixture and the heat transfer are to be determined.

Assumptions He is an ideal gas and O₂ is a nonideal gas.

Properties The molar masses of He and O₂ are 4.0 and 32.0 kg/kmol. (Table A-1)

Analysis (a) The number of moles of each gas is

$$N_{\text{He}} = \frac{m_{\text{He}}}{M_{\text{He}}} = \frac{4 \text{ kg}}{4.0 \text{ kg/kmol}} = 1 \text{ kmol}$$

$$N_{\text{O}_2} = \frac{m_{\text{O}_2}}{M_{\text{O}_2}} = \frac{8 \text{ kg}}{32 \text{ kg/kmol}} = 0.25 \text{ kmol}$$

$$N_m = N_{\text{He}} + N_{\text{O}_2} = 1 \text{ kmol} + 0.25 \text{ kmol} = 1.25 \text{ kmol}$$

Then the partial volume of each gas and the volume of the tank are

He:

$$V_{\text{He}} = \frac{N_{\text{He}} R_u T_1}{P_{m,1}} = \frac{(1 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(170 \text{ K})}{7000 \text{ kPa}} = 0.202 \text{ m}^3$$

O₂:

$$\left. \begin{aligned} P_{R_1} &= \frac{P_{m,1}}{P_{\text{cr},\text{O}_2}} = \frac{7}{5.08} = 1.38 \\ T_{R_1} &= \frac{T_1}{T_{\text{cr},\text{O}_2}} = \frac{170}{154.8} = 1.10 \end{aligned} \right\} Z_1 = 0.53 \quad (\text{Fig. A-15})$$

$$V_{\text{O}_2} = \frac{Z N_{\text{O}_2} R_u T_1}{P_{m,1}} = \frac{(0.53)(0.25 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(170 \text{ K})}{7000 \text{ kPa}} = 0.027 \text{ m}^3$$

$$V_{\text{tank}} = V_{\text{He}} + V_{\text{O}_2} = 0.202 \text{ m}^3 + 0.027 \text{ m}^3 = 0.229 \text{ m}^3$$

The partial pressure of each gas and the total final pressure is

He:

$$P_{\text{He},2} = \frac{N_{\text{He}} R_u T_2}{V_{\text{tank}}} = \frac{(1 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(220 \text{ K})}{0.229 \text{ m}^3} = 7987 \text{ kPa}$$

O₂:

$$\left. \begin{aligned} T_{R_2} &= \frac{T_2}{T_{\text{cr},\text{O}_2}} = \frac{220}{154.8} = 1.42 \\ v_{R,\text{O}_2} &= \frac{\bar{v}_{\text{O}_2}}{R_u T_{\text{cr},\text{O}_2} / P_{\text{cr},\text{O}_2}} = \frac{V_m / N_{\text{O}_2}}{R_u T_{\text{cr},\text{O}_2} / P_{\text{cr},\text{O}_2}} \\ &= \frac{(0.229 \text{ m}^3)/(0.25 \text{ kmol})}{(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(154.8 \text{ K})/(5080 \text{ kPa})} = 3.616 \end{aligned} \right\} P_R = 0.39 \quad (\text{Fig. A-15})$$

$$P_{\text{O}_2} = (P_R P_{\text{cr}})_{\text{O}_2} = (0.39)(5080 \text{ kPa}) = 1981 \text{ kPa} = 1.981 \text{ MPa}$$

$$P_{m,2} = P_{\text{He}} + P_{\text{O}_2} = 7.987 \text{ MPa} + 1.981 \text{ MPa} = \mathbf{9.97 \text{ MPa}}$$

(b) We take both gases as the system. No work or mass crosses the system boundary, therefore this is a closed system with no work interactions. Then the energy balance for this closed system reduces to

$$E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$$

$$Q_{\text{in}} = \Delta U = \Delta U_{\text{He}} + \Delta U_{\text{O}_2}$$

He:

$$\Delta U_{\text{He}} = mc_v(T_m - T_1) = (4 \text{ kg})(3.1156 \text{ kJ/kg} \cdot \text{K})(220 - 170)\text{K} = 623.1 \text{ kJ}$$

O₂:

$$\left. \begin{array}{l} T_{R_1} = 1.10 \\ P_{R_1} = 1.38 \end{array} \right\} Z_{h_1} = 2.2$$

$$\left. \begin{array}{l} T_{R_2} = 1.42 \\ P_{R_2} = \frac{9.97}{5.08} = 1.963 \end{array} \right\} Z_{h_2} = 1.2 \quad (\text{Fig. A-29})$$

$$\begin{aligned} \bar{h}_2 - \bar{h}_1 &= R_u T_{\text{cr}} (Z_{h_1} - Z_{h_2}) + (\bar{h}_2 - \bar{h}_1)_{\text{ideal}} \\ &= (8.314 \text{ kJ/kmol} \cdot \text{K})(154.8 \text{ K})(2.2 - 1.2) + (6404 - 4949) \text{ kJ/kmol} \\ &= 2742 \text{ kJ/kmol} \end{aligned}$$

Also,

$$P_{\text{He},1} = \frac{N_{\text{He}} R_u T_1}{V_{\text{tank}}} = \frac{(1 \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(170 \text{ K})}{0.229 \text{ m}^3} = 6,172 \text{ kPa}$$

$$P_{\text{O}_2,1} = P_{m,1} - P_{\text{He},1} = 7000 \text{ kPa} - 6172 \text{ kPa} = 828 \text{ kPa}$$

Thus,

$$\begin{aligned} \Delta U_{\text{O}_2} &= N_{\text{O}_2} (\bar{h}_2 - \bar{h}_1) - (P_2 V_2 - P_1 V_1) = N_{\text{O}_2} (\bar{h}_2 - \bar{h}_1) - (P_{\text{O}_2,2} - P_{\text{O}_2,1}) V_{\text{tank}} \\ &= (0.25 \text{ kmol})(2742 \text{ kJ/kmol}) - (1981 - 828)(0.229) \text{ kPa} \cdot \text{m}^3 \\ &= 421.5 \text{ kJ} \end{aligned}$$

Substituting,

$$Q_{\text{in}} = 623.1 \text{ kJ} + 421.5 \text{ kJ} = \mathbf{1045 \text{ kJ}}$$

13-97E The mass percentages of a gas mixture are given. This mixture is expanded in an adiabatic, steady-flow turbine of specified isentropic efficiency. The second law efficiency and the exergy destruction during this expansion process are to be determined.

Assumptions All gases will be modeled as ideal gases with constant specific heats.

Properties The molar masses of N_2 , He, CH_4 , and C_2H_6 are 28.0, 4.0, 16.0, and 30.0 lbm/lbmol, respectively (Table A-1E). The constant-pressure specific heats of these gases at room temperature are 0.248, 1.25, 0.532, and 0.427 Btu/lbm·R, respectively (Table A-2Ea).

Analysis For 1 lbm of mixture, the mole numbers of each component are

$$N_{N_2} = \frac{m_{N_2}}{M_{N_2}} = \frac{0.15 \text{ lbm}}{28 \text{ lbm/lbmol}} = 0.005357 \text{ lbmol}$$

$$N_{He} = \frac{m_{He}}{M_{He}} = \frac{0.05 \text{ lbm}}{4 \text{ lbm/lbmol}} = 0.0125 \text{ lbmol}$$

$$N_{CH_4} = \frac{m_{CH_4}}{M_{CH_4}} = \frac{0.6 \text{ lbm}}{16 \text{ lbm/lbmol}} = 0.0375 \text{ lbmol}$$

$$N_{C_2H_6} = \frac{m_{C_2H_6}}{M_{C_2H_6}} = \frac{0.20 \text{ lbm}}{30 \text{ lbm/lbmol}} = 0.006667 \text{ lbmol}$$

The mole number of the mixture is

$$N_m = N_{O_2} + N_{CO_2} + N_{He} = 0.005357 + 0.0125 + 0.0375 + 0.006667 = 0.06202 \text{ lbmol}$$

The apparent molecular weight of the mixture is

$$M_m = \frac{m_m}{N_m} = \frac{1 \text{ lbm}}{0.06202 \text{ lbmol}} = 16.12 \text{ lbm/lbmol}$$

The apparent gas constant of the mixture is

$$R = \frac{R_u}{M_m} = \frac{1.9858 \text{ lbm/lbmol} \cdot \text{R}}{16.12 \text{ lbm/lbmol}} = 0.1232 \text{ Btu/lbm} \cdot \text{R}$$

The constant-pressure specific heat of the mixture is determined from

$$c_p = mf_{N_2} c_{p,N_2} + mf_{He} c_{p,He} + mf_{CH_4} c_{p,CH_4} + mf_{C_2H_6} c_{p,C_2H_6}$$

$$= 0.15 \times 0.248 + 0.05 \times 1.25 + 0.60 \times 0.532 + 0.20 \times 0.427$$

$$= 0.5043 \text{ Btu/lbm} \cdot \text{R}$$

Then the constant-volume specific heat is

$$c_v = c_p - R = 0.5043 - 0.1232 = 0.3811 \text{ Btu/lbm} \cdot \text{R}$$

The specific heat ratio is

$$k = \frac{c_p}{c_v} = \frac{0.5043}{0.3811} = 1.323$$

The temperature at the end of the expansion for the isentropic process is

$$T_{2s} = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (860 \text{ R}) \left(\frac{15 \text{ psia}}{200 \text{ psia}} \right)^{0.323/1.33} = 456.8 \text{ R}$$

Using the definition of turbine isentropic efficiency, the actual outlet temperature is

$$T_2 = T_1 - \eta_{\text{turb}} (T_1 - T_{2s}) = (860 \text{ R}) - (0.85)(860 - 456.8) = 517.3 \text{ R}$$

The entropy change of the gas mixture is

$$s_2 - s_1 = c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} = (0.5043) \ln \frac{517.3}{860} - (0.1232) \ln \frac{15}{200} = 0.06270 \text{ Btu/lbm} \cdot \text{R}$$

The actual work produced is

$$w_{\text{out}} = h_1 - h_2 = c_p (T_1 - T_2) = (0.5043 \text{ Btu/lbm} \cdot \text{R})(860 - 517.3) \text{ R} = 172.8 \text{ Btu/lbm}$$

The reversible work output is

$$w_{\text{rev,out}} = h_1 - h_2 - T_0 (s_1 - s_2) = 172.8 \text{ Btu/lbm} - (537 \text{ R})(-0.06270 \text{ Btu/lbm} \cdot \text{R}) = 206.5 \text{ Btu/lbm}$$

The second-law efficiency and the exergy destruction are then

$$\eta_{\text{II}} = \frac{w_{\text{out}}}{w_{\text{rev,out}}} = \frac{172.8}{206.5} = 0.837 = \mathbf{83.7\%}$$

$$x_{\text{dest}} = w_{\text{rev,out}} - w_{\text{out}} = 206.5 - 172.8 = \mathbf{33.7 \text{ Btu/lbm}}$$

13-98 A program is to be written to determine the mole fractions of the components of a mixture of three gases with known molar masses when the mass fractions are given, and to determine the mass fractions of the components when the mole fractions are given. Also, the program is to be run for a sample case.

Analysis The problem is solved using EES, and the solution is given below.

```

Procedure Fractions(Type$,A$,B$,C$,A,B,C:mf_A,mf_B,mf_C,y_A,y_B,y_C)
{If Type$ <> ('mass fraction' OR 'mole fraction') then
Call ERROR('Type$ must be set equal to "mass fraction" or "mole fraction".')

```

13-100 Using Amagat's law, it is to be shown that $Z_m = \sum_{i=1}^k y_i Z_i$ for a real-gas mixture.

Analysis Using the compressibility factor, the volume of a component of a real-gas mixture and of the volume of the gas mixture can be expressed as

$$v_i = \frac{Z_i N_i R_u T_m}{P_m} \quad \text{and} \quad v_m = \frac{Z_m N_m R_u T_m}{P_m}$$

Amagat's law can be expressed as

$$v_m = \sum v_i(T_m, P_m).$$

Substituting,

$$\frac{Z_m N_m R_u T_m}{P_m} = \sum \frac{Z_i N_i R_u T_m}{P_m}$$

Simplifying,

$$Z_m N_m = \sum Z_i N_i$$

Dividing by N_m ,

$$Z_m = \sum y_i Z_i$$

where Z_i is determined at the mixture temperature and pressure.

Fundamentals of Engineering (FE) Exam Problems

13-101 An ideal gas mixture whose apparent molar mass is 20 kg/kmol consists of nitrogen N₂ and three other gases. If the mole fraction of nitrogen is 0.55, its mass fraction is

- (a) 0.15 (b) 0.23 (c) 0.39 (d) 0.55 (e) 0.77

Answer (e) 0.77

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
M_mix=20 "kg/kmol"
M_N2=28 "kg/kmol"
y_N2=0.55
mf_N2=(M_N2/M_mix)*y_N2
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_mf = y_N2 "Taking mass fraction to be equal to mole fraction"
W2_mf= y_N2*(M_mix/M_N2) "Using the molar mass ratio backwards"
W3_mf= 1-mf_N2 "Taking the complement of the mass fraction"
```

13-102 An ideal gas mixture consists of 2 kmol of N₂ and 6 kmol of CO₂. The mass fraction of CO₂ in the mixture is

- (a) 0.175 (b) 0.250 (c) 0.500 (d) 0.750 (e) 0.825

Answer (e) 0.825

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
N1=2 "kmol"
N2=6 "kmol"
N_mix=N1+N2
MM1=28 "kg/kmol"
MM2=44 "kg/kmol"
m_mix=N1*MM1+N2*MM2
mf2=N2*MM2/m_mix
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_mf = N2/N_mix "Using mole fraction"
W2_mf = 1-mf2 "The wrong mass fraction"
```

13-103 An ideal gas mixture consists of 2 kmol of N_2 and 4 kmol of CO_2 . The apparent gas constant of the mixture is

- (a) 0.215 kJ/kg·K (b) 0.225 kJ/kg·K (c) 0.243 kJ/kg·K (d) 0.875 kJ/kg·K (e) 1.24 kJ/kg·K

Answer (a) 0.215 kJ/kg·K

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
Ru=8.314 "kJ/kmol.K"
N1=2 "kmol"
N2=4 "kmol"

```
W1_Rmix=(R1+R2)/2 "Taking the arithmetic average of gas constants"
W2_Rmix=y1*R1+y2*R2 "Using wrong relation for Rmixture"
```

13-104 A rigid tank is divided into two compartments by a partition. One compartment contains 3 kmol of N_2 at 400 kPa pressure and the other compartment contains 7 kmol of CO_2 at 200 kPa. Now the partition is removed, and the two gases form a homogeneous mixture at 250 kPa. The partial pressure of N_2 in the mixture is

- (a) 75 kPa (b) 90 kPa (c) 125 kPa (d) 175 kPa (e) 250 kPa

Answer (a) 75 kPa

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
P1 = 400 "kPa"
P2 = 200 "kPa"
P_mix=250 "kPa"
N1=3 "kmol"
N2=7 "kmol"
MM1=28 "kg/kmol"
MM2=44 "kg/kmol"
N_mix=N1+N2
y1=N1/N_mix
y2=N2/N_mix
P_N2=y1*P_mix
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_P1= P_mix/2 "Assuming equal partial pressures"
W2_P1= mf1*P_mix; mf1=N1*MM1/(N1*MM1+N2*MM2) "Using mass fractions"
W3_P1 = P_mix*N1*P1/(N1*P1+N2*P2) "Using some kind of weighed averaging"
```

13-105 An 80-L rigid tank contains an ideal gas mixture of 5 g of N_2 and 5 g of CO_2 at a specified pressure and temperature. If N_2 were separated from the mixture and stored at mixture temperature and pressure, its volume would be

- (a) 32 L (b) 36 L (c) 40 L (d) 49 L (e) 80 L

Answer (d) 49 L

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
V_mix=80 "L"
m1=5 "g"
m2=5 "g"

Dry and Atmospheric Air: Specific and Relative Humidity

14-1C Dry air does not contain any water vapor, but atmospheric air does.

14-2C Specific humidity is the amount of water vapor present in a unit mass of dry air. Relative humidity is the ratio of the actual amount of vapor in the air at a given temperature to the maximum amount of vapor air can hold at that temperature.

14-3C Yes, the water vapor in the air can be treated as an ideal gas because of its very low partial pressure.

14-4C Yes.

14-5C Yes; by cooling the air at constant pressure.

14-6C Specific humidity will decrease but relative humidity will increase.

14-7C The specific humidity will remain constant, but the relative humidity will decrease as the temperature rises in a well-sealed room.

14-8C The specific humidity will remain constant, but the relative humidity will decrease as the temperature drops in a well-sealed room.

14-9C A tank that contains moist air at 3 atm is located in moist air that is at 1 atm. The driving force for moisture transfer is the vapor pressure difference, and thus it is possible for the water vapor to flow into the tank from surroundings if the vapor pressure in the surroundings is greater than the vapor pressure in the tank.

14-10C Insulations on *chilled water lines* are always wrapped with *vapor barrier jackets* to eliminate the possibility of vapor entering the insulation. This is because moisture that migrates through the insulation to the cold surface will condense and remain there indefinitely with no possibility of vaporizing and moving back to the outside.

14-11 A tank contains dry air and water vapor at specified conditions. The specific humidity, the relative humidity, and the volume of the tank are to be determined.

Assumptions The air and the water vapor are ideal gases.

Analysis (a) The specific humidity can be determined from its definition,

$$\omega = \frac{m_v}{m_a} = \frac{0.17 \text{ kg}}{15 \text{ kg}} = \mathbf{0.01133 \text{ kg H}_2\text{O/kg dry air}}$$

(b) The saturation pressure of water at 30°C is

$$P_g = P_{\text{sat @ } 30^\circ\text{C}} = 4.2469 \text{ kPa}$$

Then the relative humidity can be determined from

$$\phi = \frac{\omega P}{(0.622 + \omega)P_g} = \frac{(0.01133)(100 \text{ kPa})}{(0.622 + 0.01133)(4.2469 \text{ kPa})} = 0.4214 = \mathbf{42.1\%}$$

(c) The volume of the tank can be determined from the ideal gas relation for the dry air,

$$P_v = \phi P_g = (0.4214)(4.2469 \text{ kPa}) = 1.789 \text{ kPa}$$

$$P_a = P - P_v = 100 - 1.789 = 98.211 \text{ kPa}$$

$$V = \frac{m_a R_a T}{P_a} = \frac{(15 \text{ kg})(0.287 \text{ kJ/kg} \cdot \text{K})(303 \text{ K})}{98.211 \text{ kPa}} = \mathbf{13.3 \text{ m}^3}$$

15 kg dry air
0.17 kg H₂O vapor
30°C
100 kPa

14-12 A tank contains dry air and water vapor at specified conditions. The specific humidity, the relative humidity, and the volume of the tank are to be determined.

Assumptions The air and the water vapor are ideal gases.

Analysis (a) The specific humidity can be determined from its definition,

$$\omega = \frac{m_v}{m_a} = \frac{0.17 \text{ kg}}{15 \text{ kg}} = \mathbf{0.01133 \text{ kg H}_2\text{O/kg dry air}}$$

(b) The saturation pressure of water at 20°C is

$$P_g = P_{\text{sat @ } 20^\circ\text{C}} = 2.339 \text{ kPa}$$

Then the relative humidity can be determined from

$$\phi = \frac{\omega P}{(0.622 + \omega)P_g} = \frac{(0.01133)(100 \text{ kPa})}{(0.622 + 0.01133)(2.339 \text{ kPa})} = 0.7650 = \mathbf{76.5\%}$$

(c) The volume of the tank can be determined from the ideal gas relation for the dry air,

$$P_v = \phi P_g = (0.7650)(2.339 \text{ kPa}) = 1.789 \text{ kPa}$$

$$P_a = P - P_v = 100 - 1.789 = 98.211 \text{ kPa}$$

$$V = \frac{m_a R_a T}{P_a} = \frac{(15 \text{ kg})(0.287 \text{ kJ/kg} \cdot \text{K})(293 \text{ K})}{98.211 \text{ kPa}} = \mathbf{12.8 \text{ m}^3}$$

15 kg dry air
0.17 kg H₂O vapor
20°C
100 kPa

14-13 A room contains air at specified conditions and relative humidity. The partial pressure of air, the specific humidity, and the enthalpy per unit mass of dry air are to be determined.

Assumptions The air and the water vapor are ideal gases.

Analysis (a) The partial pressure of dry air can be determined from

$$P_v = \phi P_g = \phi P_{\text{sat @ } 20^\circ\text{C}} = (0.85)(2.3392 \text{ kPa}) = 1.988 \text{ kPa}$$

$$P_a = P - P_v = 98 - 1.988 = \mathbf{96.01 \text{ kPa}}$$

(b) The specific humidity of air is determined from

$$\omega = \frac{0.622 P_v}{P - P_v} = \frac{(0.622)(1.988 \text{ kPa})}{(98 - 1.988) \text{ kPa}} = \mathbf{0.0129 \text{ kg H}_2\text{O/kg dry air}}$$

(c) The enthalpy of air per unit mass of dry air is determined from

$$\begin{aligned} h &= h_a + \omega h_v \cong c_p T + \omega h_g \\ &= (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(20^\circ\text{C}) + (0.0129)(2537.4 \text{ kJ/kg}) \\ &= \mathbf{52.78 \text{ kJ/kg dry air}} \end{aligned}$$

AIR
20°C
98 kPa
85% RH

14-14 A room contains air at specified conditions and relative humidity. The partial pressure of air, the specific humidity, and the enthalpy per unit mass of dry air are to be determined.

Assumptions The air and the water vapor are ideal gases.

Analysis (a) The partial pressure of dry air can be determined from

$$P_v = \phi P_g = \phi P_{\text{sat @ } 20^\circ\text{C}} = (0.85)(2.3392 \text{ kPa}) = 1.988 \text{ kPa}$$

$$P_a = P - P_v = 85 - 1.988 = \mathbf{83.01 \text{ kPa}}$$

(b) The specific humidity of air is determined from

$$\omega = \frac{0.622 P_v}{P - P_v} = \frac{(0.622)(1.988 \text{ kPa})}{(85 - 1.988) \text{ kPa}} = \mathbf{0.0149 \text{ kg H}_2\text{O/kg dry air}}$$

(c) The enthalpy of air per unit mass of dry air is determined from

$$\begin{aligned} h &= h_a + \omega h_v \cong c_p T + \omega h_g \\ &= (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(20^\circ\text{C}) + (0.0149)(2537.4 \text{ kJ/kg}) \\ &= \mathbf{57.90 \text{ kJ/kg dry air}} \end{aligned}$$

14-15E A room contains air at specified conditions and relative humidity. The partial pressure of air, the specific humidity, and the enthalpy per unit mass of dry air are to be determined.

Assumptions The air and the water vapor are ideal gases.

Analysis (a) The partial pressure of dry air can be determined from

$$P_v = \phi P_g = \phi P_{\text{sat @ } 85^\circ\text{F}} = (0.60)(0.5966 \text{ psia}) = 0.358 \text{ psia}$$

$$P_a = P - P_v = 13.5 - 0.358 = \mathbf{13.14 \text{ psia}}$$

(b) The specific humidity of air is determined from

$$\omega = \frac{0.622 P_v}{P - P_v} = \frac{(0.622)(0.358 \text{ psia})}{(13.5 - 0.358) \text{ psia}} = \mathbf{0.0169 \text{ lbm H}_2\text{O/lbm dry air}}$$

(c) The enthalpy of air per unit mass of dry air is determined from

$$\begin{aligned} h &= h_a + \omega h_v \cong c_p T + \omega h_g \\ &= (0.24 \text{ Btu/lbm} \cdot ^\circ\text{F})(85^\circ\text{F}) + (0.0169)(1098.3 \text{ Btu/lbm}) \\ &= \mathbf{39.01 \text{ Btu/lbm dry air}} \end{aligned}$$

14-16 A tank contains saturated air at a specified temperature and pressure. The mass of dry air, the specific humidity, and the enthalpy of the air are to be determined.

Assumptions The air and the water vapor are ideal gases.

Analysis (a) The mass of dry air can be determined from the ideal gas relation for the dry air,

$$m_a = \frac{P_a \mathcal{V}}{R_a T} = \frac{[(105 - 4.2469) \text{ kPa}](8 \text{ m}^3)}{(0.287 \text{ kJ/kg} \cdot \text{K})(30 + 273.15 \text{ K})} = \mathbf{9.264 \text{ kg}}$$

(b) The relative humidity of air is 100 percent since the air is saturated. The vapor pressure is equal to the saturation pressure of water at 30°C

$$P_v = P_g = P_{\text{sat}@30^\circ\text{C}} = 4.2469 \text{ kPa}$$

The specific humidity can be determined from

$$\omega = \frac{0.622 P_v}{P - P_v} = \frac{(0.622)(4.2469 \text{ kPa})}{(105 - 4.2469) \text{ kPa}} = \mathbf{0.0262 \text{ kg H}_2\text{O/kg dry air}}$$

(c) The enthalpy of air per unit mass of dry air is determined from

$$\begin{aligned} h &= h_a + \omega h_v \cong c_p T + \omega h_g @ 30^\circ\text{C} \\ &= (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(30^\circ\text{C}) + (0.0262)(2555.6 \text{ kJ/kg}) \\ &= \mathbf{97.1 \text{ kJ/kg dry air}} \end{aligned}$$

14-17 The masses of dry air and the water vapor contained in a room at specified conditions and relative humidity are to be determined.

Assumptions The air and the water vapor are ideal gases.

Analysis The partial pressure of water vapor and dry air are determined to be

$$\begin{aligned} P_v &= \phi P_g = \phi P_{\text{sat}@26^\circ\text{C}} = (0.50)(3.364 \text{ kPa}) = 1.682 \text{ kPa} \\ P_a &= P - P_v = 93 - 1.682 = 91.32 \text{ kPa} \end{aligned}$$

The masses are determined to be

$$\begin{aligned} m_a &= \frac{P_a \mathcal{V}}{R_a T} = \frac{(91.32 \text{ kPa})(90 \text{ m}^3)}{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(299 \text{ K})} = \mathbf{95.8 \text{ kg}} \\ m_v &= \frac{P_v \mathcal{V}}{R_v T} = \frac{(1.682 \text{ kPa})(90 \text{ m}^3)}{(0.4615 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(299 \text{ K})} = \mathbf{1.10 \text{ kg}} \end{aligned}$$

14-18 Humid air is compressed in an isentropic compressor. The relative humidity of the air at the compressor outlet is to be determined.

Assumptions The air and the water vapor are ideal gases.

Properties The specific heat ratio of air at room temperature is $k = 1.4$ (Table A-2a). The saturation properties of water are to be obtained from water tables.

Analysis At the inlet,

$$P_{v,1} = \phi_1 P_{g,1} = \phi_1 P_{\text{sat}@20^\circ\text{C}} = (0.90)(2.3392 \text{ kPa}) = 2.105 \text{ kPa}$$

$$\omega_2 = \omega_1 = \frac{0.622 P_{v,1}}{P - P_{v,1}} = \frac{(0.622)(2.105 \text{ kPa})}{(100 - 2.105) \text{ kPa}} = 0.0134 \text{ kg H}_2\text{O/kg dry air}$$

Since the mole fraction of the water vapor in this mixture is very small,

$$T_2 = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (293 \text{ K}) \left(\frac{800 \text{ kPa}}{100 \text{ kPa}} \right)^{0.4/1.4} = 531 \text{ K}$$

The saturation pressure at this temperature is

$$P_{g,2} = P_{\text{sat}@258^\circ\text{C}} = 4542 \text{ kPa} \quad (\text{from EES})$$

The vapor pressure at the exit is

$$P_{v,2} = \frac{\omega_2 P_2}{\omega_2 + 0.622} = \frac{(0.0134)(800)}{0.0134 + 0.622} = 16.87 \text{ kPa}$$

The relative humidity at the exit is then

$$\phi_2 = \frac{P_{v,2}}{P_{g,2}} = \frac{16.87}{4542} = \mathbf{0.0037 = 0.37\%}$$

Dew-Point, Adiabatic Saturation, and Wet-bulb Temperatures

14-19C Dew-point temperature is the temperature at which condensation begins when air is cooled at constant pressure.

14-20C Andy's. The temperature of his glasses may be below the dew-point temperature of the room, causing condensation on the surface of the glasses.

14-21C The outer surface temperature of the glass may drop below the dew-point temperature of the surrounding air, causing the moisture in the vicinity of the glass to condense. After a while, the condensate may start dripping down because of gravity.

14-22C When the temperature falls below the dew-point temperature, dew forms on the outer surfaces of the car. If the temperature is below 0°C, the dew will freeze. At very low temperatures, the moisture in the air will freeze directly on the car windows.

14-23C When the air is saturated (100% relative humidity).

14-24C These two are approximately equal at atmospheric temperatures and pressure.

14-25 A person wearing glasses enters a warm room at a specified temperature and relative humidity from the cold outdoors. It is to be determined whether the glasses will get fogged.

Assumptions The air and the water vapor are ideal gases.

Analysis The vapor pressure P_v of the air in the house is uniform throughout, and its value can be determined from

$$P_v = \phi P_g @ 25^\circ\text{C} = (0.55)(3.1698 \text{ kPa}) = 1.743 \text{ kPa}$$

The dew-point temperature of the air in the house is

$$T_{\text{dp}} = T_{\text{sat} @ P_v} = T_{\text{sat} @ 1.743 \text{ kPa}} = \mathbf{15.3^\circ\text{C}} \quad (\text{Table A-5 or EES})$$

That is, the moisture in the house air will start condensing when the air temperature drops below 15.3°C. Since the glasses are at a lower temperature than the dew-point temperature, some moisture will condense on the glasses, and thus they **will get fogged**.

14-26 A person wearing glasses enters a warm room at a specified temperature and relative humidity from the cold outdoors. It is to be determined whether the glasses will get fogged.

Assumptions The air and the water vapor are ideal gases.

Analysis The vapor pressure P_v of the air in the house is uniform throughout, and its value can be determined from

$$P_v = \phi P_g @ 25^\circ\text{C} = (0.30)(3.1698 \text{ kPa}) = 0.9509 \text{ kPa}$$

The dew-point temperature of the air in the house is

$$T_{\text{dp}} = T_{\text{sat}} @ P_v = T_{\text{sat}} @ 0.9509 \text{ kPa} = \mathbf{6.2^\circ\text{C}}$$
 (Table A-5 or EES)

That is, the moisture in the house air will start condensing when the air temperature drops below 6.2°C . Since the glasses are at a higher temperature than the dew-point temperature, moisture will not condense on the glasses, and thus they **will not get fogged**.

14-27E A woman drinks a cool canned soda in a room at a specified temperature and relative humidity. It is to be determined whether the can will sweat.

Assumptions The air and the water vapor are ideal gases.

Analysis The vapor pressure P_v of the air in the house is uniform throughout, and its value can be determined from

$$P_v = \phi P_g @ 70^\circ\text{F} = (0.38)(0.3633 \text{ psia}) = 0.1381 \text{ psia}$$

The dew-point temperature of the air in the house is

$$T_{\text{dp}} = T_{\text{sat}} @ P_v = T_{\text{sat}} @ 0.1381 \text{ psia} = \mathbf{43.3^\circ\text{F}}$$
 (from EES)

That is, the moisture in the house air will start condensing when the air temperature drops below 43.3°C . Since the canned drink is at a lower temperature than the dew-point temperature, some moisture will condense on the can, and thus it **will sweat**.

14-28 The dry- and wet-bulb temperatures of atmospheric air at a specified pressure are given. The specific humidity, the relative humidity, and the enthalpy of air are to be determined.

Assumptions The air and the water vapor are ideal gases.

Analysis (a) We obtain the properties of water vapor from EES. The specific humidity ω_1 is determined from

$$\omega_1 = \frac{c_p(T_2 - T_1) + \omega_2 h_{fg2}}{h_{g1} - h_{f2}}$$

where T_2 is the wet-bulb temperature, and ω_2 is determined from

$$\omega_2 = \frac{0.622 P_{g2}}{P_2 - P_{g2}} = \frac{(0.622)(1.938 \text{ kPa})}{(95 - 1.938) \text{ kPa}} = 0.01295 \text{ kg H}_2\text{O/kg dry air}$$

<p>95 kPa 25°C $T_{\text{wb}} = 17^\circ\text{C}$</p>
--

Thus,

$$\omega_1 = \frac{(1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(17 - 25)^\circ\text{C} + (0.01295)(2460.6 \text{ kJ/kg})}{(2546.5 - 71.36) \text{ kJ/kg}} = \mathbf{0.00963 \text{ kg H}_2\text{O/kg dry air}}$$

(b) The relative humidity ϕ_1 is determined from

$$\phi_1 = \frac{\omega_1 P_1}{(0.622 + \omega_1) P_{g1}} = \frac{(0.00963)(95 \text{ kPa})}{(0.622 + 0.00963)(3.1698 \text{ kPa})} = 0.457 \text{ or } \mathbf{45.7\%}$$

(c) The enthalpy of air per unit mass of dry air is determined from

$$\begin{aligned} h_1 &= h_{a1} + \omega_1 h_{v1} \\ &\cong c_p T_1 + \omega_1 h_{g1} \\ &= (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(25^\circ\text{C}) + (0.00963)(2546.5 \text{ kJ/kg}) \\ &= \mathbf{49.65 \text{ kJ/kg dry air}} \end{aligned}$$

14-29 The dry- and wet-bulb temperatures of air in room at a specified pressure are given. The specific humidity, the relative humidity, and the dew-point temperature are to be determined.

Assumptions The air and the water vapor are ideal gases.

Analysis (a) We obtain the properties of water vapor from EES. The specific humidity ω_1 is determined from

$$\omega_1 = \frac{c_p(T_2 - T_1) + \omega_2 h_{fg2}}{h_{g1} - h_{f2}}$$

where T_2 is the wet-bulb temperature, and ω_2 is determined from

$$\omega_2 = \frac{0.622 P_{g2}}{P_2 - P_{g2}} = \frac{(0.622)(2.488 \text{ kPa})}{(100 - 2.488) \text{ kPa}} = 0.01587 \text{ kg H}_2\text{O/kg dry air}$$

<p>100 kPa 26°C $T_{\text{wb}} = 21^\circ\text{C}$</p>

Thus,

$$\omega_1 = \frac{(1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(21 - 26)^\circ\text{C} + (0.01587)(2451.2 \text{ kJ/kg})}{(2548.3 - 88.10) \text{ kJ/kg}} = \mathbf{0.01377 \text{ kg H}_2\text{O/kg dry air}}$$

(b) The relative humidity ϕ_1 is determined from

$$\phi_1 = \frac{\omega_1 P_1}{(0.622 + \omega_1) P_{g1}} = \frac{(0.01377)(100 \text{ kPa})}{(0.622 + 0.01377)(3.3638 \text{ kPa})} = 0.644 \text{ or } \mathbf{64.4\%}$$

(c) The vapor pressure at the inlet conditions is

$$P_{v1} = \phi_1 P_{g1} = \phi_1 P_{\text{sat}@26^\circ\text{C}} = (0.644)(3.3638 \text{ kPa}) = 2.166 \text{ kPa}$$

Thus the dew-point temperature of the air is

$$T_{\text{dp}} = T_{\text{sat}@P_v} = T_{\text{sat}@2.166 \text{ kPa}} = \mathbf{18.8^\circ\text{C}}$$

14-30 Problem 14-29 is reconsidered. The required properties are to be determined using EES at 100 and 300 kPa pressures.

Analysis The problem is solved using EES, and the solution is given below.

```
Tdb=26 [C]
Twb=21 [C]
P1=100 [kPa]
P2=300 [kPa]

h1=enthalpy(AirH2O,T=Tdb,P=P1,B=Twb)
v1=volume(AirH2O,T=Tdb,P=P1,B=Twb)
Tdp1=dewpoint(AirH2O,T=Tdb,P=P1,B=Twb)
w1=humrat(AirH2O,T=Tdb,P=P1,B=Twb)
Rh1=relhum(AirH2O,T=Tdb,P=P1,B=Twb)

h2=enthalpy(AirH2O,T=Tdb,P=P2,B=Twb)
v2=volume(AirH2O,T=Tdb,P=P2,B=Twb)
Tdp2=dewpoint(AirH2O,T=Tdb,P=P2,B=Twb)
w2=humrat(AirH2O,T=Tdb,P=P2,B=Twb)
Rh2=relhum(AirH2O,T=Tdb,P=P2,B=Twb)
```

SOLUTION

```
h1=61.25 [kJ/kg]
h2=34.16 [kJ/kg]
P1=100 [kPa]
P2=300 [kPa]
Rh1=0.6437
Rh2=0.4475
Tdb=26 [C]
Tdp1=18.76
Tdp2=13.07
Twb=21 [C]
v1=0.8777 [m^3/kg]
v2=0.2877 [m^3/kg]
w1=0.01376 [kg/kg]
w2=0.003136 [kg/kg]
```

Alternative Solution

The following EES routine can also be used to solve this problem. The above EES routine uses built-in psychrometric functions whereas the one below uses analytical expressions together with steam properties.

"Given"

```
T_db=26 [C]
T_wb=21 [C]
P=100 [kPa]
```

"Properties"

```
Fluid$='steam_iapws'
P_g1=pressure(Fluid$, T=T_db, x=1)
P_g2=pressure(Fluid$, T=T_wb, x=1)
h_g1=enthalpy(Fluid$, T=T_db, x=1)
h_g2=enthalpy(Fluid$, T=T_wb, x=1)
h_f2=enthalpy(Fluid$, T=T_wb, x=0)
h_fg2=h_g2-h_f2
c_p=1.005 [kJ/kg-C] "for air"
```

"Analysis"

"(a)"

$$w_2 = (0.622 * P_{g2}) / (P - P_{g2}) \text{ "kg H}_2\text{O/kg dry air"}$$

$$w_1 = (c_p * (T_{wb} - T_{db}) + w_2 * h_{fg2}) / (h_{g1} - h_{f2})$$

"(b)"

$$\phi_{1} = (w_1 * P) / ((0.622 + w_1) * P_{g1})$$

"(c)"

$$P_{v1} = \phi_1 * P_{g1}$$

$$T_{dp} = \text{temperature}(\text{Fluid\$}, P = P_{v1}, x = 1)$$

SOLUTION

$$c_p = 1.005 \text{ [kJ/kg-C]}$$

$$\text{Fluid\$} = \text{'steam_iapws'}$$

$$h_{f2} = 88.1 \text{ [kJ/kg]}$$

$$h_{fg2} = 2451.2 \text{ [kJ/kg]}$$

$$h_{g1} = 2548.3 \text{ [kJ/kg]}$$

$$h_{g2} = 2539.3 \text{ [kJ/kg]}$$

$$P = 100 \text{ [kPa]}$$

$$\phi_1 = 0.6439$$

$$P_{g1} = 3.3638 \text{ [kPa]}$$

$$P_{g2} = 2.488 \text{ [kPa]}$$

$$P_{v1} = 2.166 \text{ [kPa]}$$

$$T_{db} = 26 \text{ [C]}$$

$$T_{dp} = 18.8 \text{ [C]}$$

$$T_{wb} = 21 \text{ [C]}$$

$$w_1 = 0.01377$$

$$w_2 = 0.01587$$

14-31E The dry- and wet-bulb temperatures of air in room at a specified pressure are given. The specific humidity, the relative humidity, and the dew-point temperature are to be determined.

Assumptions The air and the water vapor are ideal gases.

Analysis (a) The specific humidity ω_1 is determined from

$$\omega_1 = \frac{c_p(T_2 - T_1) + \omega_2 h_{fg2}}{h_{g1} - h_{f2}}$$

where T_2 is the wet-bulb temperature, and ω_2 is determined from

$$\omega_2 = \frac{0.622 P_{g2}}{P_2 - P_{g2}} = \frac{(0.622)(0.30578 \text{ psia})}{(14.3 - 0.30578) \text{ psia}} = 0.01359 \text{ lbm H}_2\text{O/lbm dry air}$$

Thus,

$$\omega_1 = \frac{(0.24 \text{ Btu/lbm} \cdot ^\circ\text{F})(65 - 75)^\circ\text{F} + (0.01359)(1056.5 \text{ Btu/lbm})}{(1093.9 - 33.08) \text{ Btu/lbm}} = \mathbf{0.01127 \text{ lbm H}_2\text{O/lbm dry air}}$$

(b) The relative humidity ϕ_1 is determined from

$$\phi_1 = \frac{\omega_1 P_1}{(0.622 + \omega_1) P_{g1}} = \frac{(0.01127)(14.3 \text{ psia})}{(0.622 + 0.01127)(0.4302 \text{ psia})} = 0.5918 \text{ or } \mathbf{59.2\%}$$

(c) The vapor pressure at the inlet conditions is

$$P_{v1} = \phi_1 P_{g1} = \phi_1 P_{\text{sat}@75^\circ\text{F}} = (0.5918)(0.4302 \text{ psia}) = 0.2546 \text{ psia}$$

Thus the dew-point temperature of the air is

$$T_{\text{dp}} = T_{\text{sat}@P_v} = T_{\text{sat}@0.2546 \text{ psia}} = \mathbf{59.8^\circ\text{F}} \quad (\text{from EES})$$

$$\begin{aligned} &14.3 \text{ psia} \\ &75^\circ\text{F} \\ &T_{\text{wb}} = 65^\circ\text{F} \end{aligned}$$

14-32 Atmospheric air flows steadily into an adiabatic saturation device and leaves as a saturated vapor. The relative humidity and specific humidity of air are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis The exit state of the air is completely specified, and the total pressure is 98 kPa. The properties of the moist air at the exit state may be determined from EES to be

$$h_2 = 78.11 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.02079 \text{ kg H}_2\text{O/kg dry air}$$

The enthalpy of makeup water is

$$h_{w2} = h_{f@25^\circ\text{C}} = 104.83 \text{ kJ/kg} \quad (\text{Table A-4})$$

An energy balance on the control volume gives

$$h_1 + (\omega_2 - \omega_1)h_w = h_2$$

$$h_1 + (0.02079 - \omega_1)(104.83 \text{ kJ/kg}) = 78.11 \text{ kJ/kg}$$

Pressure and temperature are known for inlet air. Other properties may be determined from this equation using EES. A hand solution would require a trial-error approach. The results are

$$h_1 = 77.66 \text{ kJ/kg dry air}$$

$$\omega_1 = \mathbf{0.01654 \text{ kg H}_2\text{O/kg dry air}}$$

$$\phi_1 = \mathbf{0.4511}$$

Psychrometric Chart

14-33C They are very nearly parallel to each other.

14-34C The saturation states (located on the saturation curve).

14-35C By drawing a horizontal line until it intersects with the saturation curve. The corresponding temperature is the dew-point temperature.

14-36C No, they cannot. The enthalpy of moist air depends on ω , which depends on the total pressure.

14-37E The pressure, temperature, and relative humidity of air in a room are specified. Using the psychrometric chart, the specific humidity, the enthalpy, the wet-bulb temperature, the dew-point temperature, and the specific volume of the air are to be determined.

Analysis From the psychrometric chart (Fig. A-31) we read

(a) $\omega = 0.0165 \text{ lbm H}_2\text{O} / \text{lbm dry air}$

(b) $h = 37.8 \text{ Btu} / \text{lbm dry air}$

(c) $T_{\text{wb}} = 74.3^\circ\text{F}$

(d) $T_{\text{dp}} = 71.3^\circ\text{F}$

(e) $\nu = 14.0 \text{ ft}^3 / \text{lbm dry air}$

14-38E Problem 14-37E is reconsidered. The required properties are to be determined using EES. Also, the properties are to be obtained at an altitude of 5000 ft.

Analysis The problem is solved using EES, and the solution is given below.

```
Tdb=82 [F]
Rh=0.70
P1=14.696 [psia]
Z = 5000 [ft]
Zeqv=Z*convert(ft,m)
P2=101.325*(1-0.02256*Zeqv/1000)^5.256*convert(kPa,psia)
"Relation giving P as a function of altitude"
```

```
h1=enthalpy(AirH2O,T=Tdb,P=P1,R=Rh)
v1=volume(AirH2O,T=Tdb,P=P1,R=Rh)
Tdp1=dewpoint(AirH2O,T=Tdb,P=P1,R=Rh)
w1=humrat(AirH2O,T=Tdb,P=P1,R=Rh)
Twb1=wetbulb(AirH2O,T=Tdb,P=P1,R=Rh)
```

```
h2=enthalpy(AirH2O,T=Tdb,P=P2,R=Rh)
v2=volume(AirH2O,T=Tdb,P=P2,R=Rh)
Tdp2=dewpoint(AirH2O,T=Tdb,P=P2,R=Rh)
w2=humrat(AirH2O,T=Tdb,P=P2,R=Rh)
Twb2=wetbulb(AirH2O,T=Tdb,P=P2,R=Rh)
```

SOLUTION

$h_1 = 37.78 \text{ [Btu/lbm]}$	$h_2 = 41.54 \text{ [Btu/lbm]}$
$P_1 = 14.7 \text{ [psia]}$	$P_2 = 12.23 \text{ [psia]}$
$R_h = 0.7$	$T_{\text{db}} = 82 \text{ [F]}$
$T_{\text{dp}1} = 71.25 \text{ [F]}$	$T_{\text{dp}2} = 71.25 \text{ [F]}$
$T_{\text{wb}1} = 74.27 \text{ [F]}$	$T_{\text{wb}2} = 73.89 \text{ [F]}$
$\nu_1 = 14.02 \text{ [ft}^3\text{/lbm]}$	$\nu_2 = 16.94 \text{ [ft}^3\text{/lbm]}$
$w_1 = 0.01647 \text{ [lbm/lbm]}$	$w_2 = 0.0199 \text{ [lbm/lbm]}$
$Z = 5000 \text{ [ft]}$	$Z_{\text{eqv}} = 1524 \text{ [m]}$

14-39 The pressure and the dry- and wet-bulb temperatures of air in a room are specified. Using the psychrometric chart, the specific humidity, the enthalpy, the relative humidity, the dew-point temperature, and the specific volume of the air are to be determined.

Analysis From the psychrometric chart (Fig. A-31) we read

(a) $\omega = 0.0092 \text{ kg H}_2\text{O} / \text{kg dry air}$

(b) $h = 47.6 \text{ kJ} / \text{kg dry air}$

(c) $\phi = 49.6\%$

(d) $T_{\text{dp}} = 12.8^\circ\text{C}$

(e) $\nu = 0.855 \text{ m}^3 / \text{kg dry air}$

14-40 Problem 14-39 is reconsidered. The required properties are to be determined using EES. Also, the properties are to be obtained at an altitude of 3000 m.

Analysis The problem is solved using EES, and the solution is given below.

```
Tdb=24 [C]
Twb=17 [C]
P1=101.325 [kPa]
Z = 3000 [m]
P2=101.325*(1-0.02256*Z*convert(m,km))^5.256 "Relation giving P as function of altitude"
```

```

Tdp1=dewpoint(AirH2O,T=Tdb,P=P1,B=Twb)
w1=humrat(AirH2O,T=Tdb,P=P1,B=Twb)
Rh1=relhum(AirH2O,T=Tdb,P=P1,B=Twb)
```

```
h2=enthalpy(AirH2O,T=Tdb,P=P2,B=Twb)
v2=volume(AirH2O,T=Tdb,P=P2,B=Twb)
Tdp2=dewpoint(AirH2O,T=Tdb,P=P2,B=Twb)
w2=humrat(AirH2O,T=Tdb,P=P2,B=Twb)
Rh2=relhum(AirH2O,T=Tdb,P=P2,B=Twb)
```

SOLUTION

h1=47.61 [kJ/kg]	h2=61.68 [kJ/kg]
P1=101.3 [kPa]	P2=70.11 [kPa]
Rh1=0.4956	Rh2=0.5438
Tdb=24 [C]	Tdp1=12.81 [C]
Tdp2=14.24 [C]	Twb=17 [C]
v1=0.8542 [m ³ /kg]	v2=1.245 [m ³ /kg]
w1=0.009219 [kg/kg]	w2=0.01475 [kg/kg]
Z=3000 [m]	

Discussion The atmospheric pressure for a given elevation can also be obtained from Table A-16 of the book.

14-41 The pressure, temperature, and wet-bulb temperature of air are specified. Using the psychrometric chart, the relative humidity, specific humidity, the enthalpy, the dew-point temperature, and the water vapor pressure are to be determined.

Analysis From the psychrometric chart in Fig. A-31 or using EES psychrometric functions we obtain

$$(a) \phi = 0.480 = 48.0\%$$

$$(b) \omega = 0.0113 \text{ kg H}_2\text{O} / \text{kg dry air}$$

$$(c) h = 57.1 \text{ kJ/kg dry air}$$

$$(d) T_{\text{dp}} = 16.0^\circ\text{C}$$

$$(e) P_v = \phi P_g = \phi P_{\text{sat}} @ 28^\circ\text{C} = (0.480)(3.783 \text{ kPa}) = 1.82 \text{ kPa}$$

14-42 The pressure, temperature, and wet-bulb temperature of air are specified. The adiabatic saturation temperature is to be determined.

Analysis For an adiabatic saturation process, we obtained Eq. 14-14 in the text,

$$\omega_1 = \frac{c_p(T_2 - T_1) + \omega_2 h_{fg2}}{h_{g1} - h_{f2}}$$

This requires a trial-error solution for the adiabatic saturation temperature, T_2 . The inlet state properties are

$$\omega_1 = 0.0114 \text{ kg H}_2\text{O} / \text{kg dry air}$$

$$h_{g1} = h_g @ 28^\circ\text{C} = 2551.9 \text{ kJ/kg}$$

As a first estimate, let us take $T_2 = 20^\circ\text{C}$ (the inlet wet-bulb temperature). Also, at the exit, the relative humidity is 100% ($\phi_2 = 1$) and the pressure is 1 atm. Other properties at the exit state are

$$\omega_2 = 0.0147 \text{ kg H}_2\text{O} / \text{kg dry air}$$

$$h_{f2} = h_f @ 20^\circ\text{C} = 83.915 \text{ kJ/kg} \quad (\text{Table A - 4})$$

$$h_{fg2} = h_{fg} @ 20^\circ\text{C} = 2453.5 \text{ kJ/kg} \quad (\text{Table A - 4})$$

Substituting,

$$\omega_1 = \frac{c_p(T_2 - T_1) + \omega_2 h_{fg2}}{h_{g1} - h_{f2}} = \frac{(1.005)(20 - 28) + (0.0147)(2453.5)}{2551.9 - 83.915} = 0.0114 \text{ kg H}_2\text{O} / \text{kg dry air}$$

which is equal to the inlet specific humidity. Therefore, the adiabatic saturation temperature is

$$T_2 = \mathbf{20^\circ\text{C}}$$

Discussion This result is not surprising since the wet-bulb and adiabatic saturation temperatures are approximately equal to each other for air-water mixtures at atmospheric pressure.

14-43E The pressure, temperature, and wet-bulb temperature of air are specified. Using the psychrometric chart, the relative humidity, specific humidity, the enthalpy, the dew-point temperature, and the water vapor pressure are to be determined.

Analysis From the psychrometric chart in Fig. A-31E or using EES psychrometric functions we obtain

$$(a) \phi = 0.615 = 61.5\%$$

$$(b) \omega = 0.0188 \text{ lbm H}_2\text{O} / \text{lbm dry air}$$

$$(c) h = 42.3 \text{ Btu/lbm dry air}$$

$$(d) T_{\text{wb}} = 78.9^\circ\text{F}$$

$$(e) P_v = \phi P_g = \phi P_{\text{sat @ } 28^\circ\text{C}} = (0.615)(0.69904 \text{ psia}) = 0.430 \text{ psia}$$

14-44E The pressure, temperature, and wet-bulb temperature of air are specified. The adiabatic saturation temperature is to be determined.

Analysis For an adiabatic saturation process, we obtained Eq. 14-14 in the text,

$$\omega_1 = \frac{c_p(T_2 - T_1) + \omega_2 h_{fg2}}{h_{g1} - h_{f2}}$$

This requires a trial-error solution for the adiabatic saturation temperature, T_2 . The inlet state properties are

$$\omega_1 = 0.0188 \text{ lbm H}_2\text{O} / \text{lbm dry air} \quad (\text{Fig. A-31E})$$

$$h_{g1} = h_g @ 90^\circ\text{F} = 1100.4 \text{ Btu/lbm} \quad (\text{Table A-4E})$$

As a first estimate, let us take $T_2 = 78.9^\circ\text{F} \approx 79^\circ\text{F}$ (the inlet wet-bulb temperature). Also, at the exit, the relative humidity is 100% ($\phi_2 = 1$) and the pressure is 1 atm. Other properties at the exit state are

$$\omega_2 = 0.0215 \text{ lbm H}_2\text{O} / \text{lbm dry air}$$

$$h_{f2} = h_f @ 79^\circ\text{F} = 47.07 \text{ Btu/lbm} \quad (\text{Table A-4E})$$

$$h_{fg2} = h_{fg} @ 79^\circ\text{F} = 1048.6 \text{ Btu/lbm} \quad (\text{Table A-4E})$$

Substituting,

$$\omega_1 = \frac{c_p(T_2 - T_1) + \omega_2 h_{fg2}}{h_{g1} - h_{f2}} = \frac{(0.240)(79 - 90) + (0.0215)(1048.6)}{1100.4 - 47.07} = 0.0189 \text{ lbm H}_2\text{O} / \text{lbm dry air}$$

which is sufficiently close to the inlet specific humidity (0.0188). Therefore, the adiabatic saturation temperature is

$$T_2 \cong 79^\circ\text{F}$$

Discussion This result is not surprising since the wet-bulb and adiabatic saturation temperatures are approximately equal to each other for air-water mixtures at atmospheric pressure.

Human Comfort and Air-Conditioning

14-45C It humidifies, dehumidifies, cleans and even deodorizes the air.

14-46C (a) Perspires more, (b) cuts the blood circulation near the skin, and (c) sweats excessively.

14-47C It is the direct heat exchange between the body and the surrounding surfaces. It can make a person feel chilly in winter, and hot in summer.

14-48C It affects by removing the warm, moist air that builds up around the body and replacing it with fresh air.

14-49C The spectators. Because they have a lower level of activity, and thus a lower level of heat generation within their bodies.

14-50C Because they have a large skin area to volume ratio. That is, they have a smaller volume to generate heat but a larger area to lose it from.

14-51C It affects a body's ability to perspire, and thus the amount of heat a body can dissipate through evaporation.

14-52C Humidification is to add moisture into an environment, dehumidification is to remove it.

14-53C The metabolism refers to the burning of foods such as carbohydrates, fat, and protein in order to perform the necessary bodily functions. The metabolic rate for an average man ranges from 108 W while reading, writing, typing, or listening to a lecture in a classroom in a seated position to 1250 W at age 20 (730 at age 70) during strenuous exercise. The corresponding rates for women are about 30 percent lower. Maximum metabolic rates of trained athletes can exceed 2000 W. We are interested in metabolic rate of the occupants of a building when we deal with heating and air conditioning because the metabolic rate represents the rate at which a body generates heat and dissipates it to the room. This body heat contributes to the heating in winter, but it adds to the cooling load of the building in summer.

14-54C Sensible heat is the energy associated with a temperature change. The sensible heat loss from a human body increases as (a) the skin temperature increases, (b) the environment temperature decreases, and (c) the air motion (and thus the convection heat transfer coefficient) increases.

14-55C Latent heat is the energy released as water vapor condenses on cold surfaces, or the energy absorbed from a warm surface as liquid water evaporates. The latent heat loss from a human body increases as (a) the skin wetness increases and (b) the relative humidity of the environment decreases. The rate of evaporation from the body is related to the rate of latent heat loss by $\dot{Q}_{\text{latent}} = \dot{m}_{\text{vapor}} h_{fg}$ where h_{fg} is the latent heat of vaporization of water at the skin temperature.

14-56 A department store expects to have a specified number of people at peak times in summer. The contribution of people to the sensible, latent, and total cooling load of the store is to be determined.

Assumptions There is a mix of men, women, and children in the classroom.

Properties The average rate of heat generation from people doing light work is 115 W, and 70% of is in sensible form (see Sec. 14-6).

Analysis The contribution of people to the sensible, latent, and total cooling load of the store are

$$\begin{aligned}\dot{Q}_{\text{people,total}} &= (\text{No. of people}) \times \dot{Q}_{\text{person,total}} = 245 \times (115 \text{ W}) = \mathbf{28,180 \text{ W}} \\ \dot{Q}_{\text{people,sensible}} &= (\text{No. of people}) \times \dot{Q}_{\text{person,sensible}} = 245 \times (0.7 \times 115 \text{ W}) = \mathbf{19,720 \text{ W}} \\ \dot{Q}_{\text{people,latent}} &= (\text{No. of people}) \times \dot{Q}_{\text{person,latent}} = 245 \times (0.3 \times 115 \text{ W}) = \mathbf{8450 \text{ W}}\end{aligned}$$

14-57E There are a specified number of people in a movie theater in winter. It is to be determined if the theater needs to be heated or cooled.

Assumptions There is a mix of men, women, and children in the classroom.

Properties The average rate of heat generation from people in a movie theater is 105 W, and 70 W of it is in sensible form and 35 W in latent form.

Analysis Noting that only the sensible heat from a person contributes to the heating load of a building, the contribution of people to the heating of the building is

$$\dot{Q}_{\text{people,sensible}} = (\text{No. of people}) \times \dot{Q}_{\text{person,sensible}} = 500 \times (70 \text{ W}) = 35,000 \text{ W} = \mathbf{119,420 \text{ Btu/h}}$$

since $1 \text{ W} = 3.412 \text{ Btu/h}$. The building needs to be heated since the heat gain from people is less than the rate of heat loss of 130,000 Btu/h from the building.

14-58 The infiltration rate of a building is estimated to be 1.2 ACH. The sensible, latent, and total infiltration heat loads of the building at sea level are to be determined.

Assumptions **1** Steady operating conditions exist. **2** The air infiltrates at the outdoor conditions, and exfiltrates at the indoor conditions. **3** Excess moisture condenses at room temperature of 24°C. **4** The effect of water vapor on air density is negligible.

Properties The gas constant and the specific heat of air are $R = 0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$ and $c_p = 1.005 \text{ kJ}/\text{kg}\cdot^\circ\text{C}$ (Table A-2). The heat of vaporization of water at 24°C is $h_{fg} = h_{fg@24^\circ\text{C}} = 2444.1 \text{ kJ}/\text{kg}$ (Table A-4). The properties of the ambient and room air are determined from the psychrometric chart (Fig. A-31 or EES) to be

$$\left. \begin{array}{l} T_{\text{ambient}} = 32^\circ\text{C} \\ \phi_{\text{ambient}} = 35\% \end{array} \right\} w_{\text{ambient}} = 0.01039 \text{ kg}/\text{kg dry air}$$

$$\left. \begin{array}{l} T_{\text{room}} = 24^\circ\text{C} \\ \phi_{\text{room}} = 55\% \end{array} \right\} w_{\text{room}} = 0.01024 \text{ kg}/\text{kg dry air}$$

Analysis Noting that the infiltration of ambient air will cause the air in the cold storage room to be changed 0.9 times every hour, the air will enter the room at a mass flow rate of

$$\rho_{\text{ambient}} = \frac{P_0}{RT_0} = \frac{101.325 \text{ kPa}}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(32 + 273 \text{ K})} = 1.158 \text{ kg}/\text{m}^3$$

$$\dot{m}_{\text{air}} = \rho_{\text{ambient}} \mathcal{V}_{\text{room}} \text{ACH} = (1.158 \text{ kg}/\text{m}^3)(20 \times 13 \times 3 \text{ m}^3)(1.2 \text{ h}^{-1}) = 1084 \text{ kg}/\text{h} = 0.3010 \text{ kg}/\text{s}$$

Then the sensible, latent, and total infiltration heat loads of the room are determined to be

$$\dot{Q}_{\text{infiltration,sensible}} = \dot{m}_{\text{air}} c_p (T_{\text{ambient}} - T_{\text{room}}) = (0.3010 \text{ kg}/\text{s})(1.005 \text{ kJ}/\text{kg}\cdot^\circ\text{C})(32 - 24)^\circ\text{C} = \mathbf{2.42 \text{ kW}}$$

$$\dot{Q}_{\text{infiltration,latent}} = \dot{m}_{\text{air}} (w_{\text{ambient}} - w_{\text{room}}) h_{fg@24^\circ\text{C}} = (0.3010 \text{ kg}/\text{s})(0.01039 - 0.01024)(2444.1 \text{ kJ}/\text{kg}) = \mathbf{0.110 \text{ kW}}$$

$$\dot{Q}_{\text{infiltration,total}} = \dot{Q}_{\text{infiltration,sensible}} + \dot{Q}_{\text{infiltration,latent}} = 2.42 + 0.110 = \mathbf{2.53 \text{ kW}}$$

Discussion The specific volume of the dry air at the ambient conditions could also be determined from the psychrometric chart at ambient conditions.

14-59 The infiltration rate of a building is estimated to be 1.8 ACH. The sensible, latent, and total infiltration heat loads of the building at sea level are to be determined.

Assumptions 1 Steady operating conditions exist. 2 The air infiltrates at the outdoor conditions, and exfiltrates at the indoor conditions. 3 Excess moisture condenses at room temperature of 24°C. 4 The effect of water vapor on air density is negligible.

Properties The gas constant and the specific heat of air are $R = 0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$ and $c_p = 1.005 \text{ kJ}/\text{kg}\cdot^\circ\text{C}$ (Table A-2). The heat of vaporization of water at 24°C is $h_{fg} = h_{fg@24^\circ\text{C}} = 2444.1 \text{ kJ}/\text{kg}$ (Table A-4). The properties of the ambient and room air are determined from the psychrometric chart (Fig. A-31) to be

$$\left. \begin{array}{l} T_{\text{ambient}} = 32^\circ\text{C} \\ \phi_{\text{ambient}} = 35\% \end{array} \right\} w_{\text{ambient}} = 0.01039 \text{ kg/kg dry air}$$

$$\left. \begin{array}{l} T_{\text{room}} = 24^\circ\text{C} \\ \phi_{\text{room}} = 55\% \end{array} \right\} w_{\text{room}} = 0.01024 \text{ kg/kg dry air}$$

Analysis Noting that the infiltration of ambient air will cause the air in the cold storage room to be changed 1.8 times every hour, the air will enter the room at a mass flow rate of

$$\rho_{\text{ambient}} = \frac{P_0}{RT_0} = \frac{101.325 \text{ kPa}}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(32 + 273 \text{ K})} = 1.158 \text{ kg}/\text{m}^3$$

$$\dot{m}_{\text{air}} = \rho_{\text{ambient}} V_{\text{room}} \text{ACH} = (1.158 \text{ kg}/\text{m}^3)(20 \times 13 \times 3 \text{ m}^3)(1.8 \text{ h}^{-1}) = 1625 \text{ kg}/\text{h} = 0.4514 \text{ kg}/\text{s}$$

Then the sensible, latent, and total infiltration heat loads of the room are determined to be

$$\dot{Q}_{\text{infiltration,sensible}} = \dot{m}_{\text{air}} c_p (T_{\text{ambient}} - T_{\text{room}}) = (0.4514 \text{ kg}/\text{s})(1.005 \text{ kJ}/\text{kg}\cdot^\circ\text{C})(32 - 24)^\circ\text{C} = \mathbf{3.63 \text{ kW}}$$

$$\dot{Q}_{\text{infiltration,latent}} = \dot{m}_{\text{air}} (w_{\text{ambient}} - w_{\text{room}}) h_{fg} = (0.4514 \text{ kg}/\text{s})(0.01039 - 0.01024)(2444.1 \text{ kJ}/\text{kg}) = \mathbf{0.166 \text{ kW}}$$

$$\dot{Q}_{\text{infiltration,total}} = \dot{Q}_{\text{infiltration,sensible}} + \dot{Q}_{\text{infiltration,latent}} = 3.63 + 0.166 = \mathbf{3.80 \text{ kW}}$$

Discussion The specific volume of the dry air at the ambient conditions could also be determined from the psychrometric chart at ambient conditions.

14-60 An average person produces 0.25 kg of moisture while taking a shower. The contribution of showers of a family of four to the latent heat load of the air-conditioner per day is to be determined.

Assumptions All the water vapor from the shower is condensed by the air-conditioning system.

Properties The latent heat of vaporization of water is given to be 2450 kJ/kg.

Analysis The amount of moisture produced per day is

$$\begin{aligned} \dot{m}_{\text{vapor}} &= (\text{Moisture produced per person})(\text{No. of persons}) \\ &= (0.25 \text{ kg / person})(4 \text{ persons / day}) = 1 \text{ kg / day} \end{aligned}$$

Then the latent heat load due to showers becomes

$$\dot{Q}_{\text{latent}} = \dot{m}_{\text{vapor}} h_{fg} = (1 \text{ kg / day})(2450 \text{ kJ / kg}) = \mathbf{2450 \text{ kJ / day}}$$

14-61 There are 100 chickens in a breeding room. The rate of total heat generation and the rate of moisture production in the room are to be determined.

Assumptions All the moisture from the chickens is condensed by the air-conditioning system.

Properties The latent heat of vaporization of water is given to be 2430 kJ/kg. The average metabolic rate of chicken during normal activity is 10.2 W (3.78 W sensible and 6.42 W latent).

Analysis The total rate of heat generation of the chickens in the breeding room is

$$\dot{Q}_{\text{gen, total}} = \dot{q}_{\text{gen, total}} (\text{No. of chickens}) = (10.2 \text{ W/chicken})(100 \text{ chickens}) = \mathbf{1020 \text{ W}}$$

The latent heat generated by the chicken and the rate of moisture production are

$$\begin{aligned} \dot{Q}_{\text{gen, latent}} &= \dot{q}_{\text{gen, latent}} (\text{No. of chickens}) \\ &= (6.42 \text{ W/chicken})(100 \text{ chickens}) = 642 \text{ W} \\ &= 0.642 \text{ kW} \end{aligned}$$

$$\dot{m}_{\text{moisture}} = \frac{\dot{Q}_{\text{gen, latent}}}{h_{fg}} = \frac{0.642 \text{ kJ/s}}{2430 \text{ kJ/kg}} = 0.000264 \text{ kg/s} = \mathbf{0.264 \text{ g/s}}$$

Simple Heating and Cooling

14-62C Relative humidity decreases during a simple heating process and increases during a simple cooling process. Specific humidity, on the other hand, remains constant in both cases.

14-63C Because a horizontal line on the psychrometric chart represents a $\omega = \text{constant}$ process, and the moisture content ω of air remains constant during these processes.

14-64 Air enters a heating section at a specified state and relative humidity. The rate of heat transfer in the heating section and the relative humidity of the air at the exit are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process. **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis (a) The amount of moisture in the air remains constant ($\omega_1 = \omega_2$) as it flows through the heating section since the process involves no humidification or dehumidification. The inlet state of the air is completely specified, and the total pressure is 95 kPa. The properties of the air are determined to be

$$P_{v1} = \phi_1 P_{g1} = \phi_1 P_{\text{sat}@12^\circ\text{C}} = (0.3)(1.403 \text{ kPa}) = 0.421 \text{ kPa}$$

$$P_{a1} = P_1 - P_{v1} = 95 - 0.421 = 94.58 \text{ kPa}$$

$$\begin{aligned} \nu_1 &= \frac{R_a T_1}{P_{a1}} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K})(285 \text{ K})}{94.58 \text{ kPa}} \\ &= 0.8648 \text{ m}^3 / \text{kg dry air} \end{aligned}$$

$$\begin{aligned} \omega_1 &= \frac{0.622 P_{v1}}{P_1 - P_{v1}} = \frac{0.622(0.421 \text{ kPa})}{(95 - 0.421) \text{ kPa}} \\ &= 0.002768 \text{ kg H}_2\text{O/kg dry air} (= \omega_2) \end{aligned}$$

$$\begin{aligned} h_1 &= c_p T_1 + \omega_1 h_{g1} \\ &= (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(12^\circ\text{C}) + (0.002768)(2522.9 \text{ kJ/kg}) \\ &= 19.04 \text{ kJ/kg dry air} \end{aligned}$$

and

$$\begin{aligned} h_2 &= c_p T_2 + \omega_2 h_{g2} \\ &= (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(25^\circ\text{C}) + (0.002768)(2546.5 \text{ kJ/kg}) \\ &= 32.17 \text{ kJ/kg dry air} \end{aligned}$$

Also,

$$\dot{m}_{a1} = \frac{\dot{V}_1}{\nu_1} = \frac{6 \text{ m}^3 / \text{min}}{0.8648 \text{ m}^3 / \text{kg dry air}} = 6.938 \text{ kg/min}$$

Then the rate of heat transfer to the air in the heating section is determined from an energy balance on air in the heating section to be

$$\dot{Q}_{\text{in}} = \dot{m}_a (h_2 - h_1) = (6.938 \text{ kg/min})(32.17 - 19.04) \text{ kJ/kg} = \mathbf{91.1 \text{ kJ/min}}$$

(b) Noting that the vapor pressure of air remains constant ($P_{v2} = P_{v1}$) during a simple heating process, the relative humidity of the air at leaving the heating section becomes

$$\phi_2 = \frac{P_{v2}}{P_{g2}} = \frac{P_{v2}}{P_{\text{sat}@25^\circ\text{C}}} = \frac{0.421 \text{ kPa}}{3.1698 \text{ kPa}} = 0.133 \text{ or } \mathbf{13.3\%}$$

14-65 Humid air at a specified state is cooled at constant pressure to the dew-point temperature. The cooling required for this process is to be determined.

Assumptions **1** This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis The amount of moisture in the air remains constant ($\omega_1 = \omega_2$) as it flows through the cooling section since the process involves no humidification or dehumidification. The inlet and exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at the inlet state are determined from the psychrometric chart (Figure A-31 or EES) to be

$$h_1 = 76.1 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.0159 \text{ kg H}_2\text{O/kg dry air } (= \omega_2)$$

$$T_{dp,1} = 21.3^\circ\text{C}$$

The exit state enthalpy is

$$\left. \begin{array}{l} P = 1 \text{ atm} \\ T_2 = T_{dp,1} = 21.3^\circ\text{C} \\ \phi_2 = 1 \end{array} \right\} h_2 = 61.9 \text{ kJ/kg dry air}$$

From the energy balance on air in the cooling section,

$$q_{\text{out}} = h_1 - h_2 = 76.1 - 61.9 = \mathbf{14.2 \text{ kJ/kg dry air}}$$

14-66E Humid air at a specified state is heated at constant pressure to a specified temperature. The relative humidity at the exit and the amount of heat required are to be determined.

Assumptions **1** This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis The amount of moisture in the air remains constant ($\omega_1 = \omega_2$) as it flows through the heating section since the process involves no humidification or dehumidification. The inlet state of the air is completely specified, and the total pressure is 40 psia. The properties of the air at the inlet and exit states are determined to be

$$P_{v1} = \phi_1 P_{g1} = \phi_1 P_{\text{sat}@50^\circ\text{F}} = (0.90)(0.17812 \text{ psia}) = 0.16031 \text{ psia}$$

$$h_{g1} = h_{g@50^\circ\text{F}} = 1083.1 \text{ Btu/lbm}$$

$$\begin{aligned} \omega_1 &= \frac{0.622 P_{v1}}{P_1 - P_{v1}} = \frac{0.622(0.16031 \text{ psia})}{(40 - 0.16031) \text{ psia}} \\ &= 0.002503 \text{ lbm H}_2\text{O/lbm dry air} \end{aligned}$$

$$\begin{aligned} h_1 &= c_p T_1 + \omega_1 h_{g1} \\ &= (0.240 \text{ Btu/lbm}\cdot^\circ\text{F})(50^\circ\text{F}) + (0.002503)(1083.1 \text{ Btu/lbm}) \\ &= 14.71 \text{ Btu/lbm dry air} \end{aligned}$$

$$P_{v2} = P_{v1} = 0.16031 \text{ psia}$$

$$P_{g2} = P_{\text{sat}@120^\circ\text{F}} = 1.6951 \text{ psia}$$

$$\phi_2 = \frac{P_{v2}}{P_{g2}} = \frac{0.16031 \text{ psia}}{1.6951 \text{ psia}} = 0.0946 = \mathbf{9.46\%}$$

$$h_{g2} = h_{g@120^\circ\text{F}} = 1113.2 \text{ Btu/lbm}$$

$$\omega_2 = \omega_1$$

$$\begin{aligned} h_2 &= c_p T_2 + \omega_2 h_{g2} \\ &= (0.240 \text{ Btu/lbm}\cdot^\circ\text{F})(120^\circ\text{F}) + (0.002503)(1113.2 \text{ Btu/lbm}) \\ &= 31.59 \text{ Btu/lbm dry air} \end{aligned}$$

From the energy balance on air in the heating section,

$$q_{\text{in}} = h_2 - h_1 = 31.59 - 14.71 = \mathbf{16.9 \text{ Btu/lbm dry air}}$$

14-67 Air enters a cooling section at a specified pressure, temperature, velocity, and relative humidity. The exit temperature, the exit relative humidity of the air, and the exit velocity are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis (a) The amount of moisture in the air remains constant ($\omega_1 = \omega_2$) as it flows through the cooling section since the process involves no humidification or dehumidification. The inlet state of the air is completely specified, and the total pressure is 1 atm. The properties of the air at the inlet state are determined from the psychrometric chart (Figure A-31 or EES) to be

$$\begin{aligned} h_1 &= 76.14 \text{ kJ/kg dry air} \\ \omega_1 &= 0.01594 \text{ kg H}_2\text{O/kg dry air} (= \omega_2) \\ \nu_1 &= 0.8953 \text{ m}^3 / \text{kg dry air} \end{aligned}$$

The mass flow rate of dry air through the cooling section is

$$\begin{aligned} \dot{m}_a &= \frac{1}{\nu_1} V_1 A_1 \\ &= \frac{1}{(0.8953 \text{ m}^3 / \text{kg})} (18 \text{ m/s})(\pi \times 0.3^2 / 4 \text{ m}^2) \\ &= 1.421 \text{ kg/s} \end{aligned}$$

From the energy balance on air in the cooling section,

$$\begin{aligned} -\dot{Q}_{\text{out}} &= \dot{m}_a (h_2 - h_1) \\ -(750 / 60) \text{ kJ/s} &= (1.421 \text{ kg/s})(h_2 - 76.14) \text{ kJ/kg} \\ h_2 &= 67.35 \text{ kJ/kg dry air} \end{aligned}$$

(b) The exit state of the air is fixed now since we know both h_2 and ω_2 . From the psychrometric chart at this state we read

$$\begin{aligned} T_2 &= \mathbf{26.5^\circ\text{C}} \\ \phi_2 &= \mathbf{73.1\%} \\ \nu_2 &= 0.8706 \text{ m}^3 / \text{kg dry air} \end{aligned}$$

(c) The exit velocity is determined from the conservation of mass of dry air,

$$\begin{aligned} \dot{m}_{a1} = \dot{m}_{a2} &\longrightarrow \frac{\dot{V}_1}{\nu_1} = \frac{\dot{V}_2}{\nu_2} \longrightarrow \frac{V_1 A}{\nu_1} = \frac{V_2 A}{\nu_2} \\ V_2 &= \frac{\nu_2}{\nu_1} V_1 = \frac{0.8706}{0.8953} (18 \text{ m/s}) = \mathbf{17.5 \text{ m/s}} \end{aligned}$$

14-68 Air enters a cooling section at a specified pressure, temperature, velocity, and relative humidity. The exit temperature, the exit relative humidity of the air, and the exit velocity are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis (a) The amount of moisture in the air remains constant ($\omega_1 = \omega_2$) as it flows through the cooling section since the process involves no humidification or dehumidification. The inlet state of the air is completely specified, and the total pressure is 1 atm. The properties of the air at the inlet state are determined from the psychrometric chart (Figure A-31 or EES) to be

$$\begin{aligned} h_1 &= 76.14 \text{ kJ/kg dry air} \\ \omega_1 &= 0.01594 \text{ kg H}_2\text{O/kg dry air} (= \omega_2) \\ \nu_1 &= 0.8953 \text{ m}^3 / \text{kg dry air} \end{aligned}$$

The mass flow rate of dry air through the cooling section is

$$\begin{aligned} \dot{m}_a &= \frac{1}{\nu_1} V_1 A_1 \\ &= \frac{1}{(0.8953 \text{ m}^3 / \text{kg})} (18 \text{ m/s})(\pi \times 0.3^2 / 4 \text{ m}^2) \\ &= 1.421 \text{ kg/s} \end{aligned}$$

From the energy balance on air in the cooling section,

$$\begin{aligned} -\dot{Q}_{\text{out}} &= \dot{m}_a (h_2 - h_1) \\ -(950 / 60) \text{ kJ/s} &= (1.421 \text{ kg/s})(h_2 - 76.14) \text{ kJ/kg} \\ h_2 &= 65.00 \text{ kJ/kg dry air} \end{aligned}$$

(b) The exit state of the air is fixed now since we know both h_2 and ω_2 . From the psychrometric chart (or EES) at this state we read

$$\begin{aligned} T_2 &= \mathbf{24.3^\circ\text{C}} \\ \phi_2 &= \mathbf{83.6\%} \\ \nu_2 &= 0.8641 \text{ m}^3 / \text{kg dry air} \end{aligned}$$

(c) The exit velocity is determined from the conservation of mass of dry air,

$$\begin{aligned} \dot{m}_{a1} = \dot{m}_{a2} &\longrightarrow \frac{\dot{V}_1}{\nu_1} = \frac{\dot{V}_2}{\nu_2} \longrightarrow \frac{V_1 A}{\nu_1} = \frac{V_2 A}{\nu_2} \\ V_2 &= \frac{\nu_2}{\nu_1} V_1 = \frac{0.8641}{0.8953} (18 \text{ m/s}) = \mathbf{17.4 \text{ m/s}} \end{aligned}$$

14-69E Air enters a heating section at a specified pressure, temperature, velocity, and relative humidity. The exit temperature of air, the exit relative humidity, and the exit velocity are to be determined.

Assumptions **1** This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis (a) The amount of moisture in the air remains constant ($\omega_1 = \omega_2$) as it flows through the heating section since the process involves no humidification or dehumidification. The inlet state of the air is completely specified, and the total pressure is 1 atm. The properties of the air at the inlet state are determined from the psychrometric chart (Figure A-31E) to be

$$\begin{aligned} h_1 &= 15.3 \text{ Btu/lbm dry air} \\ \omega_1 &= 0.0030 \text{ lbm H}_2\text{O/lbm dry air} (= \omega_2) \\ \nu_1 &= 12.9 \text{ ft}^3 / \text{lbm dry air} \end{aligned}$$

The mass flow rate of dry air through the heating section is

$$\begin{aligned} \dot{m}_a &= \frac{1}{\nu_1} V_1 A_1 \\ &= \frac{1}{(12.9 \text{ ft}^3 / \text{lbm})} (25 \text{ ft/s}) (\pi \times (15/12)^2 / 4 \text{ ft}^2) = 2.38 \text{ lbm/s} \end{aligned}$$

From the energy balance on air in the heating section,

$$\begin{aligned} \dot{Q}_{\text{in}} &= \dot{m}_a (h_2 - h_1) \\ 4 \text{ kW} \left(\frac{0.9478 \text{ Btu/s}}{1 \text{ kW}} \right) &= (2.38 \text{ lbm/s}) (h_2 - 15.3) \text{ Btu/lbm} \\ h_2 &= 16.9 \text{ Btu/lbm dry air} \end{aligned}$$

The exit state of the air is fixed now since we know both h_2 and ω_2 . From the psychrometric chart at this state we read

$$T_2 = \mathbf{56.6^\circ\text{F}}$$

$$(b) \quad \phi_2 = \mathbf{31.4\%}$$

$$\nu_2 = 13.1 \text{ ft}^3 / \text{lbm dry air}$$

(c) The exit velocity is determined from the conservation of mass of dry air,

$$\dot{m}_{a1} = \dot{m}_{a2} \longrightarrow \frac{\dot{V}_1}{\nu_1} = \frac{\dot{V}_2}{\nu_2} \longrightarrow \frac{V_1 A}{\nu_1} = \frac{V_2 A}{\nu_2}$$

Thus,

$$V_2 = \frac{\nu_2}{\nu_1} V_1 = \frac{13.1}{12.9} (25 \text{ ft/s}) = \mathbf{25.4 \text{ ft/s}}$$

Heating with Humidification

14-70C To achieve a higher level of comfort. Very dry air can cause dry skin, respiratory difficulties, and increased static electricity.

14-71 Air is first heated and then humidified by water vapor. The amount of steam added to the air and the amount of heat transfer to the air are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Properties The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at various states are determined from the psychrometric chart (Figure A-31) to be

$$h_1 = 31.1 \text{ kJ / kg dry air}$$

$$\omega_1 = 0.0064 \text{ kg H}_2\text{O / kg dry air} (= \omega_2)$$

$$h_2 = 36.2 \text{ kJ / kg dry air}$$

$$h_3 = 58.1 \text{ kJ / kg dry air}$$

$$\omega_3 = 0.0129 \text{ kg H}_2\text{O / kg dry air}$$

Analysis (a) The amount of moisture in the air remains constant it flows through the heating section ($\omega_1 = \omega_2$), but increases in the humidifying section ($\omega_3 > \omega_2$). The amount of steam added to the air in the heating section is

$$\Delta\omega = \omega_3 - \omega_2 = 0.0129 - 0.0064 = \mathbf{0.0065 \text{ kg H}_2\text{O / kg dry air}}$$

(b) The heat transfer to the air in the heating section per unit mass of air is

$$q_{\text{in}} = h_2 - h_1 = 36.2 - 31.1 = \mathbf{5.1 \text{ kJ / kg dry air}}$$

14-72E Air is first heated and then humidified by water vapor. The amount of steam added to the air and the amount of heat transfer to the air are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Properties The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at various states are determined from the psychrometric chart (Figure A-31E or EES) to be

$$\begin{aligned} h_1 &= 10.69 \text{ Btu/lbmdry air} \\ \omega_1 &= 0.002122 \text{ lbm H}_2\text{O/lbm dry air} \\ \omega_2 &= \omega_1 = 0.002122 \text{ lbm H}_2\text{O/lbm dry air} \\ h_2 &= 17.93 \text{ Btu/lbmdry air} \\ h_3 &= 29.16 \text{ Btu/lbmdry air} \\ \omega_3 &= 0.01017 \text{ lbm H}_2\text{O/lbm dry air} \end{aligned}$$

Analysis (a) The amount of moisture in the air remains constant as it flows through the heating section ($\omega_1 = \omega_2$), but increases in the humidifying section ($\omega_3 > \omega_2$). The amount of steam added to the air in the heating section is

$$\Delta\omega = \omega_3 - \omega_2 = 0.01017 - 0.002122 = \mathbf{0.00805 \text{ lbm H}_2\text{O/lbmdry air}}$$

(b) The heat transfer to the air in the heating section per unit mass of air is

$$q_{\text{in}} = h_2 - h_1 = 17.93 - 10.69 = \mathbf{7.24 \text{ Btu/lbmdry air}}$$

14-73 Air is first heated and then humidified by wet steam. The temperature and relative humidity of air at the exit of heating section, the rate of heat transfer, and the rate at which water is added to the air are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Properties The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at various states are determined from the psychrometric chart (Figure A-31) to be

$$h_1 = 23.5 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.0053 \text{ kg H}_2\text{O/kg dry air} (= \omega_2)$$

$$\nu_1 = 0.809 \text{ m}^3/\text{kg dry air}$$

$$h_3 = 42.3 \text{ kJ/kg dry air}$$

$$\omega_3 = 0.0087 \text{ kg H}_2\text{O/kg dry air}$$

Analysis (a) The amount of moisture in the air remains constant it flows through the heating section ($\omega_1 = \omega_2$), but increases in the humidifying section ($\omega_3 > \omega_2$). The mass flow rate of dry air is

$$\dot{m}_a = \frac{\dot{V}_1}{\nu_1} = \frac{35 \text{ m}^3/\text{min}}{0.809 \text{ m}^3/\text{kg}} = 43.3 \text{ kg/min}$$

Noting that $Q = W = 0$, the energy balance on the humidifying section can be expressed as

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\text{no (steady)}}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\begin{aligned} \sum \dot{m}_i h_i = \sum \dot{m}_e h_e &\longrightarrow \dot{m}_w h_w + \dot{m}_a h_2 = \dot{m}_a h_3 \\ (\omega_3 - \omega_2) h_w + h_2 &= h_3 \end{aligned}$$

Solving for h_2 ,

$$h_2 = h_3 - (\omega_3 - \omega_2) h_{g@100^\circ\text{C}} = 42.3 - (0.0087 - 0.0053)(2675.6) = 33.2 \text{ kJ/kg dry air}$$

Thus at the exit of the heating section we have $\omega_2 = 0.0053 \text{ kg H}_2\text{O dry air}$ and $h_2 = 33.2 \text{ kJ/kg dry air}$, which completely fixes the state. Then from the psychrometric chart we read

$$T_2 = \mathbf{19.5^\circ\text{C}}$$

$$\phi_2 = \mathbf{37.8\%}$$

(b) The rate of heat transfer to the air in the heating section is

$$\dot{Q}_{\text{in}} = \dot{m}_a (h_2 - h_1) = (43.3 \text{ kg/min})(33.2 - 23.5) \text{ kJ/kg} = \mathbf{420 \text{ kJ/min}}$$

(c) The amount of water added to the air in the humidifying section is determined from the conservation of mass equation of water in the humidifying section,

$$\dot{m}_w = \dot{m}_a (\omega_3 - \omega_2) = (43.3 \text{ kg/min})(0.0087 - 0.0053) = \mathbf{0.15 \text{ kg/min}}$$

14-74 Air is first heated and then humidified by wet steam. The temperature and relative humidity of air at the exit of heating section, the rate of heat transfer, and the rate at which water is added to the air are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$).

2 Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis (a) The amount of moisture in the air also remains constant it flows through the heating section ($\omega_1 = \omega_2$), but increases in the humidifying section ($\omega_3 > \omega_2$). The inlet and the exit states of the air are completely specified, and the total pressure is 95 kPa. The properties of the air at various states are determined to be

$$P_{v1} = \phi_1 P_{g1} = \phi_1 P_{\text{sat}@10^\circ\text{C}} = (0.70)(1.2281 \text{ kPa}) = 0.860 \text{ kPa} (= P_{v2})$$

$$P_{a1} = P_1 - P_{v1} = 95 - 0.860 = 94.14 \text{ kPa}$$

$$\nu_1 = \frac{R_a T_1}{P_{a1}} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K})(283 \text{ K})}{94.14 \text{ kPa}} = 0.863 \text{ m}^3 / \text{kg dry air}$$

$$\omega_1 = \frac{0.622 P_{v1}}{P_1 - P_{v1}} = \frac{0.622(0.86 \text{ kPa})}{(95 - 0.86) \text{ kPa}} = 0.00568 \text{ kg H}_2\text{O/kg dry air} (= \omega_2)$$

$$h_1 = c_p T_1 + \omega_1 h_{g1} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(10^\circ\text{C}) + (0.00568)(2519.2 \text{ kJ/kg}) = 24.36 \text{ kJ/kg dry air}$$

$$P_{v3} = \phi_3 P_{g3} = \phi_3 P_{\text{sat}@20^\circ\text{C}} = (0.60)(2.3392 \text{ kPa}) = 1.40 \text{ kPa}$$

$$\omega_3 = \frac{0.622 P_{v3}}{P_3 - P_{v3}} = \frac{0.622(1.40 \text{ kPa})}{(95 - 1.40) \text{ kPa}} = 0.00930 \text{ kg H}_2\text{O/kg dry air}$$

$$h_3 = c_p T_3 + \omega_3 h_{g3} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(20^\circ\text{C}) + (0.0093)(2537.4 \text{ kJ/kg}) = 43.70 \text{ kJ/kg dry air}$$

Also,
$$\dot{m}_a = \frac{\dot{V}_1}{\nu_1} = \frac{35 \text{ m}^3 / \text{min}}{0.863 \text{ m}^3 / \text{kg}} = 40.6 \text{ kg/min}$$

Noting that $Q = W = 0$, the energy balance on the humidifying section gives

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\text{steady}}{\approx} 0 \longrightarrow \dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_e h_e = \sum \dot{m}_i h_i \longrightarrow \dot{m}_w h_w + \dot{m}_a h_2 = \dot{m}_a h_3 \longrightarrow (\omega_3 - \omega_2) h_w + h_2 = h_3$$

$$h_2 = h_3 - (\omega_3 - \omega_2) h_{g@100^\circ\text{C}} = 43.7 - (0.0093 - 0.00568) \times 2675.6 = 34.0 \text{ kJ/kg dry air}$$

Thus at the exit of the heating section we have $\omega = 0.00568 \text{ kg H}_2\text{O dry air}$ and $h_2 = 34.0 \text{ kJ/kg dry air}$, which completely fixes the state. The temperature of air at the exit of the heating section is determined from the definition of enthalpy,

$$h_2 = c_p T_2 + \omega_2 h_{g2} \cong c_p T_2 + \omega_2 (2500.9 + 1.82 T_2)$$

$$34.0 = (1.005) T_2 + (0.00568)(2500.9 + 1.82 T_2)$$

Solving for h_2 , yields

$$T_2 = \mathbf{19.5^\circ\text{C}}$$

The relative humidity at this state is

$$\phi_2 = \frac{P_{v2}}{P_{g2}} = \frac{P_{v2}}{P_{\text{sat}@19.5^\circ\text{C}}} = \frac{0.860 \text{ kPa}}{2.2759 \text{ kPa}} = 0.377 \text{ or } \mathbf{37.7\%}$$

(b) The rate of heat transfer to the air in the heating section becomes

$$\dot{Q}_{\text{in}} = \dot{m}_a (h_2 - h_1) = (40.6 \text{ kg/min})(34.0 - 24.36) \text{ kJ/kg} = \mathbf{391 \text{ kJ/min}}$$

(c) The amount of water added to the air in the humidifying section is determined from the conservation of mass equation of water in the humidifying section,

$$\dot{m}_w = \dot{m}_a (\omega_3 - \omega_2) = (40.6 \text{ kg/min})(0.0093 - 0.00568) = \mathbf{0.147 \text{ kg/min}}$$

Cooling with Dehumidification

14-75C To drop its relative humidity to more desirable levels.

14-76 Air is cooled and dehumidified by a window air conditioner. The rates of heat and moisture removal from the air are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Properties The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at various states are determined from the psychrometric chart (Figure A-31) to be

$$h_1 = 86.3 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.0211 \text{ kg H}_2\text{O/kg dry air}$$

$$\nu_1 = 0.894 \text{ m}^3/\text{kg dry air}$$

and

$$h_2 = 42.0 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.0107 \text{ kg H}_2\text{O/kg dry air}$$

Also,

$$h_w \cong h_f @ 15^\circ\text{C} = 62.982 \text{ kJ/kg} \quad (\text{Table A-4})$$

Analysis (a) The amount of moisture in the air decreases due to dehumidification ($\omega_2 < \omega_1$). The mass flow rate of air is

$$\dot{m}_{a1} = \frac{\dot{V}_1}{\nu_1} = \frac{2 \text{ m}^3/\text{min}}{0.894 \text{ m}^3/\text{kg dry air}} = 2.238 \text{ kg/min}$$

Applying the water mass balance and energy balance equations to the combined cooling and dehumidification section,

Water Mass Balance:

$$\sum \dot{m}_{w,i} = \sum \dot{m}_{w,e} \longrightarrow \dot{m}_{a1}\omega_1 = \dot{m}_{a2}\omega_2 + \dot{m}_w$$

$$\dot{m}_w = \dot{m}_a(\omega_1 - \omega_2) = (2.238 \text{ kg/min})(0.0211 - 0.0107) = \mathbf{0.0233 \text{ kg/min}}$$

Energy Balance:

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\phi=0(\text{steady})}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \dot{Q}_{\text{out}} + \sum \dot{m}_e h_e$$

$$\dot{Q}_{\text{out}} = \dot{m}_{a1}h_1 - (\dot{m}_{a2}h_2 + \dot{m}_w h_w) = \dot{m}_a(h_1 - h_2) - \dot{m}_w h_w$$

$$\dot{Q}_{\text{out}} = (2.238 \text{ kg/min})(86.3 - 42.0) \text{ kJ/kg} - (0.0233 \text{ kg/min})(62.982 \text{ kJ/kg})$$

$$= \mathbf{97.7 \text{ kJ/min}}$$

14-77E Air is cooled and dehumidified at constant pressure. The amount of water removed from the air and the cooling requirement are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Properties The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at various states are determined from the psychrometric chart (Figure A-31E) to be

$$h_1 = 52.2 \text{ Btu/lbm dry air}$$

$$\omega_1 = 0.0278 \text{ kg H}_2\text{O/kg dry air}$$

and

$$\phi_2 = 1.0$$

$$h_2 = 20.3 \text{ Btu/lbm dry air}$$

$$\omega_2 = 0.0076 \text{ kg H}_2\text{O/kg dry air}$$

Also,

$$h_w \cong h_f @ 60^\circ\text{F} = 28.08 \text{ Btu/lbm} \quad (\text{Table A-4})$$

Analysis The amount of moisture in the air decreases due to dehumidification ($\omega_2 < \omega_1$). Applying the water mass balance and energy balance equations to the combined cooling and dehumidification section,

Water Mass Balance:

$$\sum \dot{m}_{w,i} = \sum \dot{m}_{w,e} \longrightarrow \dot{m}_{a1} \omega_1 = \dot{m}_{a2} \omega_2 + \dot{m}_w$$

$$\Delta\omega = \omega_1 - \omega_2 = 0.0278 - 0.0076 = \mathbf{0.0202 \text{ lbm H}_2\text{O/lbm dry air}}$$

Energy Balance:

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\phi^0(\text{steady})}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \dot{Q}_{\text{out}} + \sum \dot{m}_e h_e$$

$$\dot{Q}_{\text{out}} = \dot{m}_{a1} h_1 - (\dot{m}_{a2} h_2 + \dot{m}_w h_w) = \dot{m}_a (h_1 - h_2) - \dot{m}_w h_w$$

$$q_{\text{out}} = h_1 - h_2 - (\omega_1 - \omega_2) h_w$$

$$= (52.2 - 20.3) \text{ Btu/lbm} - (0.0202)(28.08)$$

$$= \mathbf{31.3 \text{ Btu/lbm dry air}}$$

14-78  Air is cooled by passing it over a cooling coil through which chilled water flows. The rate of heat transfer, the mass flow rate of water, and the exit velocity of airstream are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process. **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis (a) The saturation pressure of water at 32°C is 4.76 kPa (Table A-4). Then the dew point temperature of the incoming air stream at 32°C becomes

$$T_{dp} = T_{sat @ P_v} = T_{sat @ 0.7 \times 4.76 \text{ kPa}} = 25.8^\circ\text{C} \quad (\text{Table A-5})$$

since air is cooled to 20°C, which is below its dew point temperature, some of the moisture in the air will condense. The amount of moisture in the air decreases due to dehumidification ($\omega_2 < \omega_1$). The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. Then the properties of the air at both states are determined from the psychrometric chart (Fig. A-31 or EES) to be

$$h_1 = 86.35 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.02114 \text{ kg H}_2\text{O/kg dry air}$$

$$\nu_1 = 0.8939 \text{ m}^3/\text{kg dry air}$$

and

$$h_2 = 57.43 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.0147 \text{ kg H}_2\text{O/kg dry air}$$

$$\nu_2 = 0.8501 \text{ m}^3/\text{kg dry air}$$

Also, $h_w \cong h_f @ 20^\circ\text{C} = 83.91 \text{ kJ/kg}$ (Table A-4)

Then,

$$\dot{V}_1 = V_1 A_1 = V_1 \frac{\pi D^2}{4} = (120 \text{ m/min}) \left(\frac{\pi (0.4 \text{ m})^2}{4} \right) = 15.08 \text{ m}^3/\text{min}$$

$$\dot{m}_{a1} = \frac{\dot{V}_1}{\nu_1} = \frac{15.08 \text{ m}^3/\text{min}}{0.8939 \text{ m}^3/\text{kg dry air}} = 16.87 \text{ kg/min}$$

Applying the water mass balance and the energy balance equations to the combined cooling and dehumidification section (excluding the water),

$$\text{Water Mass Balance:} \quad \sum \dot{m}_{w,i} = \sum \dot{m}_{w,e} \quad \longrightarrow \quad \dot{m}_{a1} \omega_1 = \dot{m}_{a2} \omega_2 + \dot{m}_w$$

$$\dot{m}_w = \dot{m}_a (\omega_1 - \omega_2) = (16.87 \text{ kg/min})(0.02114 - 0.0147) = 0.1086 \text{ kg/min}$$

$$\text{Energy Balance:} \quad \dot{E}_{in} - \dot{E}_{out} = \Delta \dot{E}_{system} \stackrel{\text{no (steady)}}{\approx} 0 \quad \longrightarrow \quad \dot{E}_{in} = \dot{E}_{out}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e + \dot{Q}_{out} \quad \longrightarrow \quad \dot{Q}_{out} = \dot{m}_{a1} h_1 - (\dot{m}_{a2} h_2 + \dot{m}_w h_w) = \dot{m}_a (h_1 - h_2) - \dot{m}_w h_w$$

$$\dot{Q}_{out} = (16.87 \text{ kg/min})(86.35 - 57.43) \text{ kJ/kg} - (0.1086 \text{ kg/min})(83.91 \text{ kJ/kg}) = \mathbf{478.7 \text{ kJ/min}}$$

(b) Noting that the heat lost by the air is gained by the cooling water, the mass flow rate of the cooling water is determined from

$$\dot{Q}_{cooling\ water} = \dot{m}_{cooling\ water} \Delta h = \dot{m}_{cooling\ water} c_p \Delta T$$

$$\dot{m}_{cooling\ water} = \frac{\dot{Q}_w}{c_p \Delta T} = \frac{478.7 \text{ kJ/min}}{(4.18 \text{ kJ/kg} \cdot ^\circ\text{C})(6^\circ\text{C})} = \mathbf{19.09 \text{ kg/min}}$$

(c) The exit velocity is determined from the conservation of mass of dry air,

$$\dot{m}_{a1} = \dot{m}_{a2} \quad \longrightarrow \quad \frac{\dot{V}_1}{\nu_1} = \frac{\dot{V}_2}{\nu_2} \quad \longrightarrow \quad \frac{V_1 A}{\nu_1} = \frac{V_2 A}{\nu_2}$$

$$V_2 = \frac{\nu_2}{\nu_1} V_1 = \frac{0.8501}{0.8939} (120 \text{ m/min}) = \mathbf{114 \text{ m/min}}$$

14-79 Problem 14-78 is reconsidered. A general solution of the problem in which the input variables may be supplied and parametric studies performed is to be developed and the process is to be shown in the psychrometric chart for each set of input variables.

Analysis The problem is solved using EES, and the solution is given below.

14-80 Air is cooled by passing it over a cooling coil. The rate of heat transfer, the mass flow rate of water, and the exit velocity of airstream are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process. **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis (a) The dew point temperature of the incoming air stream at 35°C is

$$\begin{aligned} P_{v1} &= \phi_1 P_{g1} = \phi_1 P_{\text{sat}@32^\circ\text{C}} \\ &= (0.7)(4.76 \text{ kPa}) = 3.332 \text{ kPa} \\ T_{\text{dp}} &= T_{\text{sat}@P_v} = T_{\text{sat}@3.332 \text{ kPa}} = 25.8^\circ\text{C} \end{aligned}$$

Since air is cooled to 20°C, which is below its dew point temperature, some of the moisture in the air will condense.

The amount of moisture in the air decreases due to dehumidification ($\omega_2 < \omega_1$). The inlet and the exit states of the air are completely specified, and the total pressure is 95 kPa. Then the properties of the air at both states are determined to be

$$\begin{aligned} P_{a1} &= P_1 - P_{v1} = 95 - 3.332 = 91.67 \text{ kPa} \\ \nu_1 &= \frac{R_a T_1}{P_{a1}} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K})(305 \text{ K})}{91.67 \text{ kPa}} = 0.9549 \text{ m}^3 / \text{kg dry air} \\ \omega_1 &= \frac{0.622 P_{v1}}{P_1 - P_{v1}} = \frac{0.622(3.332 \text{ kPa})}{(95 - 3.332) \text{ kPa}} = 0.02261 \text{ kg H}_2\text{O/kg dry air} \\ h_1 &= c_p T_1 + \omega_1 h_{g1} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(32^\circ\text{C}) + (0.02261)(2559.2 \text{ kJ/kg}) = 90.01 \text{ kJ/kg dry air} \end{aligned}$$

and

$$\begin{aligned} P_{v2} &= \phi_2 P_{g2} = (1.00)P_{\text{sat}@20^\circ\text{C}} = 2.339 \text{ kPa} \\ \nu_2 &= \frac{R_a T_2}{P_{a2}} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K})(293 \text{ K})}{(95 - 2.339) \text{ kPa}} = 0.9075 \text{ m}^3 / \text{kg dry air} \\ \omega_2 &= \frac{0.622 P_{v2}}{P_2 - P_{v2}} = \frac{0.622(2.339 \text{ kPa})}{(95 - 2.339) \text{ kPa}} = 0.0157 \text{ kg H}_2\text{O/kg dry air} \\ h_2 &= c_p T_2 + \omega_2 h_{g2} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(20^\circ\text{C}) + (0.0157)(2537.4 \text{ kJ/kg}) = 59.94 \text{ kJ/kg dry air} \end{aligned}$$

Also,

$$h_w \cong h_f @ 20^\circ\text{C} = 83.915 \text{ kJ/kg} \quad (\text{Table A-4})$$

Then,

$$\begin{aligned} \dot{V}_1 &= V_1 A_1 = V_1 \frac{\pi D^2}{4} = (120 \text{ m/min}) \left(\frac{\pi(0.4 \text{ m})^2}{4} \right) = 15.08 \text{ m}^3 / \text{min} \\ \dot{m}_{a1} &= \frac{\dot{V}_1}{\nu_1} = \frac{15.08 \text{ m}^3 / \text{min}}{0.9549 \text{ m}^3 / \text{kg dry air}} = 15.79 \text{ kg/min} \end{aligned}$$

Applying the water mass balance and energy balance equations to the combined cooling and dehumidification section (excluding the water),

Water Mass Balance:

$$\sum \dot{m}_{w,i} = \sum \dot{m}_{w,e} \longrightarrow \dot{m}_{a1}\omega_1 = \dot{m}_{a2}\omega_2 + \dot{m}_w$$

$$\dot{m}_w = \dot{m}_a(\omega_1 - \omega_2) = (15.79 \text{ kg/min})(0.02261 - 0.0157) = 0.1090 \text{ kg/min}$$

Energy Balance:

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\text{no (steady)}}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e + \dot{Q}_{\text{out}} \rightarrow \dot{Q}_{\text{out}} = \dot{m}_{a1}h_1 - (\dot{m}_{a2}h_2 + \dot{m}_w h_w) = \dot{m}_a(h_1 - h_2) - \dot{m}_w h_w$$

$$\dot{Q}_{\text{out}} = (15.79 \text{ kg/min})(90.01 - 59.94) \text{ kJ/kg} - (0.1090 \text{ kg/min})(83.915 \text{ kJ/kg}) = \mathbf{465.7 \text{ kJ/min}}$$

(b) Noting that the heat lost by the air is gained by the cooling water, the mass flow rate of the cooling water is determined from

$$\dot{Q}_{\text{coolingwater}} = \dot{m}_{\text{coolingwater}} \Delta h = \dot{m}_{\text{coolingwater}} c_p \Delta T$$

$$\dot{m}_{\text{coolingwater}} = \frac{\dot{Q}_w}{c_p \Delta T} = \frac{465.7 \text{ kJ/min}}{(4.18 \text{ kJ/kg} \cdot ^\circ\text{C})(6^\circ\text{C})} = \mathbf{18.57 \text{ kg/min}}$$

(c) The exit velocity is determined from the conservation of mass of dry air,

$$\dot{m}_{a1} = \dot{m}_{a2} \longrightarrow \frac{\dot{V}_1}{\nu_1} = \frac{\dot{V}_2}{\nu_2} \longrightarrow \frac{V_1 A}{\nu_1} = \frac{V_2 A}{\nu_2}$$

$$V_2 = \frac{\nu_2}{\nu_1} V_1 = \frac{0.9075}{0.9549} (120 \text{ m/min}) = \mathbf{114 \text{ m/min}}$$

14-81E Air is cooled by passing it over a cooling coil through which chilled water flows. The rate of heat transfer, the mass flow rate of water, and the exit velocity of airstream are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process. **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis (a) The saturation pressure of water at 90°F is 0.69904 psia (Table A-4E). Then, the dew point temperature of the incoming air stream at 90°F becomes

$$T_{dp} = T_{sat @ P_v} = T_{sat @ 0.6 \times 0.69904 \text{ psia}} = 74.2^\circ\text{F} \quad (\text{Table A-5E})$$

Since air is cooled to 70°F, which is below its dew point temperature, some of the moisture in the air will condense. The amount of moisture in the air decreases due to dehumidification ($\omega_2 < \omega_1$). The inlet and the exit states of the air are completely specified, and the total pressure is 14.7 psia. Then the properties of the air at both states are determined from the psychrometric chart (Fig. A-31E) to be

$$\begin{aligned} h_1 &= 41.8 \text{ Btu/lbm dry air} \\ \omega_1 &= 0.0183 \text{ lbm H}_2\text{O/lbm dry air} \\ \nu_1 &= 14.26 \text{ ft}^3/\text{lbm dry air} \end{aligned}$$

and

$$\begin{aligned} h_2 &= 34.1 \text{ Btu/lbm dry air} \\ \omega_2 &= 0.0158 \text{ lbm H}_2\text{O/lbm dry air} \\ \nu_2 &= 13.68 \text{ ft}^3/\text{lbm dry air} \end{aligned}$$

Also,

$$h_w \cong h_f @ 70^\circ\text{F} = 38.08 \text{ Btu/lbm} \quad (\text{Table A-4E})$$

$$\dot{V}_1 = V_1 A_1 = V_1 \frac{\pi D^2}{4} = (600 \text{ ft/min}) \left(\frac{\pi (1 \text{ ft})^2}{4} \right) = 471 \text{ ft}^3/\text{min}$$

Then,

$$\dot{m}_{a1} = \frac{\dot{V}_1}{\nu_1} = \frac{471 \text{ ft}^3/\text{min}}{14.26 \text{ ft}^3/\text{lbm dry air}} = 33.0 \text{ lbm/min}$$

Applying the water mass balance and the energy balance equations to the combined cooling and dehumidification section (excluding the water),

$$\text{Water Mass Balance:} \quad \sum \dot{m}_{w,i} = \sum \dot{m}_{w,e} \quad \longrightarrow \quad \dot{m}_{a1} \omega_1 = \dot{m}_{a2} \omega_2 + \dot{m}_w$$

$$\dot{m}_w = \dot{m}_a (\omega_1 - \omega_2) = (33.0 \text{ lbm/min})(0.0183 - 0.0158) = 0.083 \text{ lbm/min}$$

$$\text{Energy Balance:} \quad \dot{E}_{in} - \dot{E}_{out} = \Delta \dot{E}_{system} \stackrel{\text{steady}}{\approx} 0 \quad \longrightarrow \quad \dot{E}_{in} = \dot{E}_{out}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e + \dot{Q}_{out} \quad \longrightarrow \quad \dot{Q}_{out} = \dot{m}_a h_1 - (\dot{m}_a h_2 + \dot{m}_w h_w) = \dot{m}_a (h_1 - h_2) - \dot{m}_w h_w$$

$$\dot{Q}_{out} = (33.0 \text{ lbm/min})(41.8 - 34.1) \text{ Btu/lbm} - (0.083 \text{ lbm/min})(38.08 \text{ Btu/lbm}) = \mathbf{250.9 \text{ Btu/min}}$$

(b) Noting that the heat lost by the air is gained by the cooling water, the mass flow rate of the cooling water is determined from

$$\begin{aligned} \dot{Q}_{cooling\ water} &= \dot{m}_{cooling\ water} \Delta h = \dot{m}_{cooling\ water} c_p \Delta T \\ \dot{m}_{cooling\ water} &= \frac{\dot{Q}_w}{c_p \Delta T} = \frac{250.9 \text{ Btu/min}}{(1.0 \text{ Btu/lbm} \cdot ^\circ\text{F})(14^\circ\text{F})} = \mathbf{17.9 \text{ lbm/min}} \end{aligned}$$

(c) The exit velocity is determined from the conservation of mass of dry air,

$$\begin{aligned} \dot{m}_{a1} = \dot{m}_{a2} &\quad \longrightarrow \quad \frac{\dot{V}_1}{\nu_1} = \frac{\dot{V}_2}{\nu_2} \quad \longrightarrow \quad \frac{V_1 A}{\nu_1} = \frac{V_2 A}{\nu_2} \\ V_2 &= \frac{\nu_2}{\nu_1} V_1 = \frac{13.68}{14.26} (600 \text{ ft/min}) = \mathbf{576 \text{ ft/min}} \end{aligned}$$

14-82E Problem 14-81E is reconsidered. The effect of the total pressure of the air on the required results is to be studied.

Analysis The problem is solved using EES, and the solution is given below.

14-83E Air is cooled by passing it over a cooling coil through which chilled water flows. The rate of heat transfer, the mass flow rate of water, and the exit velocity of airstream are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process. **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis (a) The dew point temperature of the incoming air stream at 90°F is

$$P_{v1} = \phi_1 P_{g1} = \phi_1 P_{\text{sat}@90^\circ\text{F}} = (0.6)(0.69904 \text{ psia}) = 0.42 \text{ psi} \quad (\text{Tables A-4E and A-5E})$$

$$T_{\text{dp}} = T_{\text{sat}@P_v} = T_{\text{sat}@0.42 \text{ psia}} = 74^\circ\text{F}$$

Since air is cooled to 70°F, which is below its dew point temperature, some of the moisture in the air will condense.

The mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$), but the amount of moisture in the air decreases due to dehumidification ($\omega_2 < \omega_1$). The inlet and the exit states of the air are completely specified, and the total pressure is 14.4 psia. Then the properties of the air at both states are determined to be

$$P_{a1} = P_1 - P_{v1} = 14.4 - 0.42 = 13.98 \text{ psia}$$

$$v_1 = \frac{R_a T_1}{P_{a1}} = \frac{(0.3704 \text{ psia} \cdot \text{ft}^3 / \text{lbm} \cdot \text{R})(550 \text{ R})}{13.98 \text{ psia}} = 14.57 \text{ ft}^3 / \text{lbm dry air}$$

$$\omega_1 = \frac{0.622 P_{v1}}{P_1 - P_{v1}} = \frac{0.622(0.42 \text{ psia})}{(14.4 - 0.42) \text{ psia}} = 0.0187 \text{ lbm H}_2\text{O/lbm dry air}$$

$$h_1 = c_p T_1 + \omega_1 h_{g1} = (0.24 \text{ Btu/lbm} \cdot ^\circ\text{F})(90^\circ\text{F}) + (0.0187)(1100.4 \text{ Btu/lbm}) = 42.18 \text{ Btu/lbm dry air}$$

and

$$P_{v2} = \phi_2 P_{g2} = (1.00)P_{\text{sat}@70^\circ\text{F}} = 0.36 \text{ psia}$$

$$P_{a2} = P_2 - P_{v2} = 14.4 - 0.36 = 14.04 \text{ psia}$$

$$v_2 = \frac{R_a T_2}{P_{a2}} = \frac{(0.3704 \text{ psia} \cdot \text{ft}^3 / \text{lbm} \cdot \text{R})(530 \text{ R})}{14.04 \text{ psia}} = 14.0 \text{ ft}^3 / \text{lbm dry air}$$

$$\omega_2 = \frac{0.622 P_{v2}}{P_2 - P_{v2}} = \frac{0.622(0.36 \text{ psia})}{(14.4 - 0.36) \text{ psia}} = 0.0159 \text{ lbm H}_2\text{O/lbm dry air}$$

$$h_2 = c_p T_2 + \omega_2 h_{g2} = (0.24 \text{ Btu/lbm} \cdot ^\circ\text{F})(70^\circ\text{F}) + (0.0159)(1091.8 \text{ Btu/lbm}) = 34.16 \text{ Btu/lbm dry air}$$

Also,

$$h_w \cong h_f @ 70^\circ\text{F} = 38.08 \text{ Btu/lbm} \quad (\text{Table A-4E})$$

Then,

$$\dot{V}_1 = V_1 A_1 = V_1 \frac{\pi D^2}{4} = (600 \text{ ft/min}) \left(\frac{\pi (1 \text{ ft})^2}{4} \right) = 471 \text{ ft}^3 / \text{min}$$

$$\dot{m}_{a1} = \frac{\dot{V}_1}{v_1} = \frac{471 \text{ ft}^3 / \text{min}}{14.57 \text{ ft}^3 / \text{lbm dry air}} = 32.3 \text{ lbm/min}$$

Applying the water mass balance and energy balance equations to the combined cooling and dehumidification section (excluding the water),

Water Mass Balance:

$$\sum \dot{m}_{w,i} = \sum \dot{m}_{w,e} \quad \longrightarrow \quad \dot{m}_{a1} \omega_1 = \dot{m}_{a2} \omega_2 + \dot{m}_w$$

$$\dot{m}_w = \dot{m}_a(\omega_1 - \omega_2) = (32.3 \text{ lbm/min})(0.0187 - 0.0159) = 0.0904 \text{ lbm/min}$$

Energy balance:

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\approx 0 \text{ (steady)}}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e + \dot{Q}_{\text{out}} \rightarrow \dot{Q}_{\text{out}} = \dot{m}_{a1} h_1 - (\dot{m}_{a2} h_2 + \dot{m}_w h_w) = \dot{m}_a (h_1 - h_2) - \dot{m}_w h_w$$

$$\begin{aligned} \dot{Q}_{\text{out}} &= (32.3 \text{ lbm/min})(42.18 - 34.16) \text{ Btu/lbm} - (0.0904 \text{ lbm/min})(38.08 \text{ Btu/lbm}) \\ &= \mathbf{255.6 \text{ Btu/min}} \end{aligned}$$

(b) Noting that the heat lost by the air is gained by the cooling water, the mass flow rate of the cooling water is determined from

$$\dot{Q}_{\text{coolingwater}} = \dot{m}_{\text{coolingwater}} \Delta h = \dot{m}_{\text{coolingwater}} c_p \Delta T$$

$$\dot{m}_{\text{coolingwater}} = \frac{\dot{Q}_w}{c_p \Delta T} = \frac{255.6 \text{ Btu/min}}{(1.0 \text{ Btu/lbm} \cdot ^\circ\text{F})(14^\circ\text{F})} = \mathbf{18.3 \text{ lbm/min}}$$

(c) The exit velocity is determined from the conservation of mass of dry air,

$$\dot{m}_{a1} = \dot{m}_{a2} \longrightarrow \frac{\dot{V}_1}{\nu_1} = \frac{\dot{V}_2}{\nu_2} \longrightarrow \frac{V_1 A}{\nu_1} = \frac{V_2 A}{\nu_2}$$

$$V_2 = \frac{\nu_2}{\nu_1} V_1 = \frac{14.0}{14.57} (600 \text{ ft/s}) = \mathbf{577 \text{ ft/min}}$$

14-84 Air flows through an air conditioner unit. The inlet and exit states are specified. The rate of heat transfer and the mass flow rate of condensate water are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis The inlet state of the air is completely specified, and the total pressure is 101 kPa. The properties of the air at the inlet state may be determined from (Fig. A-31) or using EES psychrometric functions to be (we used EES)

$$\begin{aligned}h_1 &= 57.20 \text{ kJ/kg dry air} \\ \omega_1 &= 0.01056 \text{ kg H}_2\text{O/kg dry air} \\ \phi_1 &= 0.3972\end{aligned}$$

The partial pressure of water vapor at the exit state is

$$P_{v2} = P_{\text{sat}@6.5^\circ\text{C}} = 0.9682 \text{ kPa} \quad (\text{Table A - 4})$$

The saturation pressure at the exit state is

$$P_{g2} = P_{\text{sat}@20^\circ\text{C}} = 2.339 \text{ kPa} \quad (\text{Table A - 4})$$

Then, the relative humidity at the exit state becomes

$$\phi_2 = \frac{P_{v2}}{P_{g2}} = \frac{0.9682}{2.339} = 0.4139$$

Now, the exit state is also fixed. The properties are obtained from EES to be

$$\begin{aligned}h_2 &= 35.41 \text{ kJ/kg dry air} \\ \omega_2 &= 0.006019 \text{ kg H}_2\text{O/kg dry air} \\ \nu_2 &= 0.8412 \text{ m}^3/\text{kg}\end{aligned}$$

The mass flow rate of dry air is

$$\dot{m}_a = \frac{\dot{V}_2}{\nu_2} = \frac{800 \text{ m}^3/\text{min}}{0.8412 \text{ m}^3/\text{kg}} = 951.1 \text{ kg/min}$$

The mass flow rate of condensate water is

$$\dot{m}_w = \dot{m}_a(\omega_1 - \omega_2) = (951.1 \text{ kg/min})(0.01056 - 0.006019) = 4.319 \text{ kg/min} = \mathbf{259 \text{ kg/h}}$$

The enthalpy of condensate water is

$$h_{w2} = h_{f@20^\circ\text{C}} = 83.91 \text{ kJ/kg} \quad (\text{Table A - 4})$$

An energy balance on the control volume gives

$$\begin{aligned}\dot{m}_a h_1 &= \dot{Q}_{\text{out}} + \dot{m}_a h_2 + \dot{m}_w h_{w2} \\ (951.1 \text{ kg/min})(57.20 \text{ kJ/kg}) &= \dot{Q}_{\text{out}} + (951.1 \text{ kg/min})(35.41 \text{ kJ/kg}) + (4.321 \text{ kg/min})(83.91 \text{ kJ/kg}) \\ \dot{Q}_{\text{out}} &= 20,360 \text{ kJ/min} = \mathbf{339 \text{ kW}}\end{aligned}$$

14-85 Atmospheric air enters the evaporator of an automobile air conditioner at a specified pressure, temperature, and relative humidity. The dew point and wet bulb temperatures at the inlet to the evaporator section, the required heat transfer rate from the atmospheric air to the evaporator fluid, and the rate of condensation of water vapor in the evaporator section are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis The inlet and exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at the inlet and exit states may be determined from the psychrometric chart (Fig. A-31) or using EES psychrometric functions to be (we used EES)

$$T_{dp1} = 15.7^\circ\text{C}$$

$$T_{wb1} = 19.5^\circ\text{C}$$

$$h_1 = 55.60 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.01115 \text{ kg H}_2\text{O/kg dry air}$$

$$\nu_1 = 0.8655 \text{ m}^3 / \text{kg dry air}$$

$$h_2 = 27.35 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.00686 \text{ kg H}_2\text{O/kg dry air}$$

The mass flow rate of dry air is

$$\dot{m}_a = \frac{\dot{V}_1}{\nu_1} = \frac{V_{car} \text{ ACH}}{\nu_1} = \frac{(2 \text{ m}^3/\text{change})(5 \text{ changes/min})}{0.8655 \text{ m}^3} = 11.55 \text{ kg/min}$$

The mass flow rates of vapor at the inlet and exit are

$$\dot{m}_{v1} = \omega_1 \dot{m}_a = (0.01115)(11.55 \text{ kg/min}) = 0.1288 \text{ kg/min}$$

$$\dot{m}_{v2} = \omega_2 \dot{m}_a = (0.00686)(11.55 \text{ kg/min}) = 0.07926 \text{ kg/min}$$

An energy balance on the control volume gives

$$\dot{m}_a h_1 = \dot{Q}_{out} + \dot{m}_a h_2 + \dot{m}_w h_{w2}$$

where the the enthalpy of condensate water is

$$h_{w2} = h_{f@10^\circ\text{C}} = 42.02 \text{ kJ/kg} \quad (\text{Table A-4})$$

and the rate of condensation of water vapor is

$$\dot{m}_w = \dot{m}_{v1} - \dot{m}_{v2} = 0.1288 - 0.07926 = \mathbf{0.0495 \text{ kg/min}}$$

Substituting,

$$\begin{aligned} \dot{m}_a h_1 &= \dot{Q}_{out} + \dot{m}_a h_2 + \dot{m}_w h_{w2} \\ (11.55 \text{ kg/min})(55.60 \text{ kJ/kg}) &= \dot{Q}_{out} + (11.55 \text{ kg/min})(27.35 \text{ kJ/kg}) + (0.0495 \text{ kg/min})(42.02 \text{ kJ/kg}) \\ \dot{Q}_{out} &= 324.4 \text{ kJ/min} = \mathbf{5.41 \text{ kW}} \end{aligned}$$

Discussion We could not show the process line between the states 1 and 2 because we do not know the process path.

14-86 Air is cooled and dehumidified at constant pressure. The cooling required is provided by a simple ideal vapor-compression refrigeration system using refrigerant-134a as the working fluid. The exergy destruction in the total system per 1000 m³ of dry air is to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Properties The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at various states are determined from the psychrometric chart (Figure A-31) to be

$$\begin{aligned} h_1 &= 106.8 \text{ kJ/kg dry air} \\ \omega_1 &= 0.0292 \text{ kg H}_2\text{O/kg dry air} \\ \nu_1 &= 0.905 \text{ m}^3/\text{kg dry air} \end{aligned}$$

and

$$\begin{aligned} h_2 &= 52.7 \text{ kJ/kg dry air} \\ \omega_2 &= 0.0112 \text{ kg H}_2\text{O/kg dry air} \end{aligned}$$

We assume that the condensate leaves this system at the average temperature of the air inlet and exit. Then, from Table A-4,

$$h_w \cong h_f @ 28^\circ\text{C} = 117.4 \text{ kJ/kg}$$

Analysis The amount of moisture in the air decreases due to dehumidification ($\omega_2 < \omega_1$). The mass of air is

$$m_a = \frac{\nu_1}{\nu_1} = \frac{1000 \text{ m}^3}{0.905 \text{ m}^3/\text{kg dry air}} = 1105 \text{ kg}$$

Applying the water mass balance and energy balance equations to the combined cooling and dehumidification section,

Water Mass Balance:

$$\begin{aligned} \sum \dot{m}_{w,i} &= \sum \dot{m}_{w,e} \longrightarrow \dot{m}_{a1}\omega_1 = \dot{m}_{a2}\omega_2 + \dot{m}_w \\ m_w &= m_a(\omega_1 - \omega_2) = (1105 \text{ kg})(0.0292 - 0.0112) = 19.89 \text{ kg} \end{aligned}$$

Energy Balance:

$$\begin{aligned} \dot{E}_{in} - \dot{E}_{out} &= \Delta \dot{E}_{system} \overset{\phi^0(\text{steady})}{=} 0 \\ \dot{E}_{in} &= \dot{E}_{out} \\ \sum \dot{m}_i h_i &= \dot{Q}_{out} + \sum \dot{m}_e h_e \\ \dot{Q}_{out} &= \dot{m}_{a1}h_1 - (\dot{m}_{a2}h_2 + \dot{m}_w h_w) = \dot{m}_a(h_1 - h_2) - \dot{m}_w h_w \\ Q_{out} &= m_a(h_1 - h_2) - m_w h_w \\ Q_{out} &= (1105 \text{ kg})(106.8 - 52.7) \text{ kJ/kg} - (19.89 \text{ kg})(117.4 \text{ kJ/kg}) = 57,450 \text{ kJ} \end{aligned}$$

We obtain the properties for the vapor-compression refrigeration cycle as follows (Tables A-11, through A-13):

$$\begin{aligned} \left. \begin{aligned} T_1 &= 4^\circ\text{C} \\ \text{sat. vapor} \end{aligned} \right\} \begin{aligned} h_1 &= h_g @ 4^\circ\text{C} = 252.77 \text{ kJ/kg} \\ s_1 &= s_g @ 4^\circ\text{C} = 0.92927 \text{ kJ/kg} \cdot \text{K} \end{aligned} \\ \left. \begin{aligned} P_2 &= P_{\text{sat}} @ 39.4^\circ\text{C} = 1 \text{ MPa} \\ s_2 &= s_1 \end{aligned} \right\} \begin{aligned} h_2 &= 275.29 \text{ kJ/kg} \end{aligned} \\ \left. \begin{aligned} P_3 &= 1 \text{ MPa} \\ \text{sat. liquid} \end{aligned} \right\} \begin{aligned} h_3 &= h_f @ 1 \text{ MPa} = 107.32 \text{ kJ/kg} \\ s_3 &= s_f @ 1 \text{ MPa} = 0.39189 \text{ kJ/kg} \cdot \text{K} \end{aligned} \\ h_4 &\cong h_3 = 107.32 \text{ kJ/kg} \quad (\text{throttling}) \\ \left. \begin{aligned} T_4 &= 4^\circ\text{C} \\ h_4 &= 107.32 \text{ kJ/kg} \end{aligned} \right\} \begin{aligned} x_4 &= 0.2561 \\ s_4 &= 0.4045 \text{ kJ/kg} \cdot \text{K} \end{aligned} \end{aligned}$$

The mass flow rate of refrigerant-134a is

$$m_R = \frac{Q_L}{h_1 - h_4} = \frac{57,450 \text{ kJ}}{(252.77 - 107.32) \text{ kJ/kg}} = 395.0 \text{ kg}$$

The amount of heat rejected from the condenser is

$$Q_H = m_R(h_2 - h_3) = (395.0 \text{ kg})(275.29 - 107.32) \text{ kJ/kg} = 66,350 \text{ kJ}$$

Next, we calculate the exergy destruction in the components of the refrigeration cycle:

$$X_{\text{destroyed},12} = m_R T_0 (s_2 - s_1) = 0 \quad (\text{since the process is isentropic})$$

$$\begin{aligned} X_{\text{destroyed},23} &= T_0 \left(m_R (s_3 - s_2) + \frac{Q_H}{T_H} \right) \\ &= (305 \text{ K}) \left((395 \text{ kg})(0.39189 - 0.92927) \text{ kJ/kg} \cdot \text{K} + \frac{66,350 \text{ kJ}}{305 \text{ K}} \right) = 1609 \text{ kJ} \end{aligned}$$

$$X_{\text{destroyed},34} = m_R T_0 (s_4 - s_3) = (395 \text{ kg})(305 \text{ K})(0.4045 - 0.39189) \text{ kJ/kg} \cdot \text{K} = 1519 \text{ kJ}$$

The entropies of water vapor in the air stream are

$$s_{g1} = s_g @ 32^\circ\text{C} = 8.4114 \text{ kJ/kg} \cdot \text{K}$$

$$s_{g2} = s_g @ 24^\circ\text{C} = 8.5782 \text{ kJ/kg} \cdot \text{K}$$

The entropy change of water vapor in the air stream is

$$\Delta S_{\text{vapor}} = m_a (\omega_2 s_{g2} - \omega_1 s_{g1}) = (1105)(0.0112 \times 8.5782 - 0.0292 \times 8.4114) = -165.2 \text{ kJ/K}$$

The entropy of water leaving the cooling section is

$$S_w = m_w s_f @ 28^\circ\text{C} = (19.89 \text{ kg})(0.4091 \text{ kJ/kg} \cdot \text{K}) = 8.14 \text{ kJ/K}$$

The partial pressures of water vapor and dry air for air streams are

$$P_{v1} = \phi_1 P_{g1} = \phi_1 P_{\text{sat}} @ 32^\circ\text{C} = (0.95)(4.760 \text{ kPa}) = 4.522 \text{ kPa}$$

$$P_{a1} = P_1 - P_{v1} = 101.325 - 4.522 = 96.80 \text{ kPa}$$

$$P_{v2} = \phi_2 P_{g2} = \phi_2 P_{\text{sat}} @ 24^\circ\text{C} = (0.60)(2.986 \text{ kPa}) = 1.792 \text{ kPa}$$

$$P_{a2} = P_2 - P_{v2} = 101.325 - 1.792 = 99.53 \text{ kPa}$$

The entropy change of dry air is

$$\begin{aligned} \Delta S_a &= m_a (s_2 - s_1) = m_a \left(c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_{a2}}{P_{a1}} \right) \\ &= (1105) \left[(1.005) \ln \frac{297}{305} - (0.287) \ln \frac{99.53}{96.80} \right] = -38.34 \text{ kJ/kg dry air} \end{aligned}$$

The entropy change of R-134a in the evaporator is

$$\Delta S_{R,41} = m_R (s_1 - s_4) = (395 \text{ kg})(0.92927 - 0.4045) = 207.3 \text{ kJ/K}$$

An entropy balance on the evaporator gives

$$S_{\text{gen, evaporator}} = \Delta S_{R,41} + \Delta S_{\text{vapor}} + \Delta S_a + S_w = 207.3 + (-165.2) + (-38.34) + 8.14 = 11.90 \text{ kJ/K}$$

Then, the exergy destruction in the evaporator is

$$X_{\text{dest}} = T_0 S_{\text{gen, evaporator}} = (305 \text{ K})(11.90 \text{ kJ/K}) = 3630 \text{ kJ}$$

Finally the total exergy destruction is

$$\begin{aligned} X_{\text{dest, total}} &= X_{\text{dest, compressor}} + X_{\text{dest, condenser}} + X_{\text{dest, throttle}} + X_{\text{dest, evaporator}} \\ &= 0 + 1609 + 1519 + 3630 \\ &= \mathbf{6758 \text{ kJ}} \end{aligned}$$

The greatest exergy destruction occurs in the evaporator. Note that heat is absorbed from humid air and rejected to the ambient air at 32°C (305 K), which is also taken as the dead state temperature.

14-87 Air is cooled, dehumidified and heated at constant pressure. The system hardware and the psychrometric diagram are to be sketched, the dew point temperatures, and the heat transfer are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis (a) The schematic of the cooling and dehumidification process and the the process on the psychrometric chart are given below. The psychrometric chart is obtained from the Property Plot feature of EES.

(b) The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at the inlet and exit states are determined from the psychrometric chart (Figure A-31 or EES) to be

$$T_{dp1} = \mathbf{26.7^\circ\text{C}}$$

$$h_1 = 96.5 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.0222 \text{ kg H}_2\text{O/kg dry air}$$

and

$$T_{dp2} = \mathbf{5.3^\circ C}$$

$$\phi_2 = 46\%$$

$$h_2 = 31.1 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.00551 \text{ kg H}_2\text{O/kg dry air}$$

Also,

$$h_w \cong h_f @ 5.3^\circ C = 22.2 \text{ kJ/kg} \quad (\text{Table A-4})$$

The enthalpy of water is evaluated at 5.3°C, which is the temperature of air at the end of the dehumidification process.

(c) Applying the water mass balance and energy balance equations to the combined cooling and dehumidification section,

Water Mass Balance:

$$\sum \dot{m}_{w,i} = \sum \dot{m}_{w,e} \longrightarrow \dot{m}_{a1}\omega_1 = \dot{m}_{a2}\omega_2 + \dot{m}_w$$

$$\dot{m}_w = \dot{m}_a(\omega_1 - \omega_2)$$

Energy Balance:

$$\dot{E}_{in} - \dot{E}_{out} = \Delta \dot{E}_{system} \stackrel{\phi^0(\text{steady})}{=} 0$$

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\sum \dot{m}_i h_i = \dot{Q}_{out} + \sum \dot{m}_e h_e$$

$$\dot{Q}_{out} = \dot{m}_{a1}h_1 - (\dot{m}_{a2}h_2 + \dot{m}_w h_w)$$

$$= \dot{m}_a(h_1 - h_2) - \dot{m}_w h_w$$

$$= \dot{m}_a(h_1 - h_2) - \dot{m}_a(\omega_1 - \omega_2)h_w$$

Substituting,

$$\begin{aligned} q_{out} &= (h_1 - h_2) - (\omega_1 - \omega_2)h_w \\ &= (96.5 - 31.1) \text{ kJ/kg} - (0.0222 - 0.00551)(22.2 \text{ kJ/kg}) \\ &= \mathbf{65.1 \text{ kJ/kg}} \end{aligned}$$

Evaporative Cooling

14-88C Evaporative cooling is the cooling achieved when water evaporates in dry air. It will not work on humid climates.

14-89C During evaporation from a water body to air, the latent heat of vaporization will be equal to *convection* heat transfer from the air when *conduction* from the lower parts of the water body to the surface is negligible, and temperature of the surrounding surfaces is at about the temperature of the water surface so that the *radiation* heat transfer is negligible.

14-90C In steady operation, the mass transfer process does not have to involve heat transfer. However, a mass transfer process that involves phase change (evaporation, sublimation, condensation, melting etc.) must involve heat transfer. For example, the evaporation of water from a lake into air (mass transfer) requires the transfer of latent heat of water at a specified temperature to the liquid water at the surface (heat transfer).

14-91 Air is cooled by an evaporative cooler. The exit temperature of the air is to be determined.

Analysis The enthalpy of air at the inlet is determined from

$$\begin{aligned}
 P_{v1} &= \phi_1 P_{g1} = \phi_1 P_{\text{sat}@40^\circ\text{C}} = (0.25)(7.3851 \text{ kPa}) = 1.846 \text{ kPa} \\
 \omega_1 &= \frac{0.622 P_{v1}}{P_1 - P_{v1}} = \frac{0.622(1.846 \text{ kPa})}{(95 - 1.846) \text{ kPa}} = 0.01233 \text{ kg H}_2\text{O/kg dry air} \\
 h_1 &= c_p T_1 + \omega_1 h_{g1} \\
 &= (1.005 \text{ kJ/kg}\cdot^\circ\text{C})(40^\circ\text{C}) + (0.01233)(2573.5 \text{ kJ/kg}) \\
 &= 71.93 \text{ kJ/kg dry air}
 \end{aligned}$$

Assuming the liquid water is supplied at a temperature not much different than the exit temperature of the air stream, the evaporative cooling process follows a line of constant wet-bulb temperature, which is almost parallel to the constant enthalpy lines. That is,

$$h_2 \cong h_1 = 71.93 \text{ kJ/kg dry air}$$

Also,

$$\omega_2 = \frac{0.622 P_{v2}}{P_2 - P_{v2}} = \frac{0.622 P_{g2}}{95 - P_{g2}}$$

since air leaves the evaporative cooler saturated. Substituting this into the definition of enthalpy, we obtain

$$\begin{aligned}
 h_2 &= c_p T_2 + \omega_2 h_{g2} \cong c_p T_2 + \omega_2 (2500.9 + 1.82 T_2) \\
 71.93 \text{ kJ/kg} &= (1.005 \text{ kJ/kg}\cdot^\circ\text{C})T_2 + \frac{0.622 P_{g2}}{95 - P_{g2}} (2500.9 + 1.82 T_2) \text{ kJ/kg}
 \end{aligned}$$

By trial and error, the exit temperature is determined to be

$$T_2 = \mathbf{23.1^\circ\text{C}}.$$

14-92E Air is cooled by an evaporative cooler. The exit temperature of the air is to be determined.

Analysis The enthalpy of air at the inlet is determined from

$$P_{v1} = \phi_1 P_{g1} = \phi_1 P_{\text{sat}@93^\circ\text{F}} = (0.30)(0.7676 \text{ psia}) = 0.230 \text{ psia}$$

$$\omega_1 = \frac{0.622 P_{v1}}{P_1 - P_{v1}} = \frac{0.622(0.230 \text{ psia})}{(14.5 - 0.230) \text{ psia}}$$

$$= 0.01004 \text{ lbm H}_2\text{O/lbm dry air}$$

$$h_1 = c_p T_1 + \omega_1 h_{g1}$$

$$= (0.24 \text{ Btu/lbm}\cdot^\circ\text{F})(93^\circ\text{F}) + (0.01004)(1101.7 \text{ Btu/lbm})$$

$$= 33.38 \text{ Btu/lbmdry air}$$

Assuming the liquid water is supplied at a temperature not much different than the exit temperature of the air stream, the evaporative cooling process follows a line of constant wet-bulb temperature, which is almost parallel to the constant enthalpy lines. That is,

$$h_2 \cong h_1 = 33.38 \text{ Btu/lbmdry air}$$

Also,

$$\omega_2 = \frac{0.622 P_{v2}}{P_2 - P_{v2}} = \frac{0.622 P_{g2}}{14.5 - P_{g2}}$$

since air leaves the evaporative cooler saturated. Substituting this into the definition of enthalpy, we obtain

$$h_2 = c_p T_2 + \omega_2 h_{g2} \cong c_p T_2 + \omega_2 (1060.9 + 0.435 T_2)$$

$$33.38 \text{ Btu/lbm} = (0.24 \text{ Btu/lbm}\cdot^\circ\text{F})T_2 + \frac{0.622 P_{g2}}{14.5 - P_{g2}} (1060.9 + 0.435 T_2)$$

By trial and error, the exit temperature is determined to be

$$T_2 = \mathbf{69.0^\circ\text{F}}$$

14-93 Air is cooled by an evaporative cooler. The exit temperature of the air and the required rate of water supply are to be determined.

Analysis (a) From the psychrometric chart (Fig. A-31 or EES) at 40°C and 20% relative humidity we read

$$T_{wb1} = 22.04^\circ\text{C}$$

$$\omega_1 = 0.009199 \text{ kg H}_2\text{O/kg dry air}$$

$$\nu_1 = 0.9002 \text{ m}^3/\text{kg dry air}$$

Assuming the liquid water is supplied at a temperature not much different than the exit temperature of the air stream, the evaporative cooling process follows a line of constant wet-bulb temperature. That is,

$$T_{wb2} \cong T_{wb1} = 22.04^\circ\text{C}$$

At this wet-bulb temperature and 90% relative humidity we read

$$T_2 = \mathbf{23.3^\circ\text{C}}$$

$$\omega_2 = 0.01619 \text{ kg H}_2\text{O/kg dry air}$$

Thus air will be cooled to 23.3°C in this evaporative cooler.

(b) The mass flow rate of dry air is

$$\dot{m}_a = \frac{\dot{V}_1}{\nu_1} = \frac{7 \text{ m}^3 / \text{min}}{0.9002 \text{ m}^3 / \text{kg dry air}} = 7.776 \text{ kg/min}$$

Then the required rate of water supply to the evaporative cooler is determined from

$$\begin{aligned} \dot{m}_{\text{supply}} &= \dot{m}_{w2} - \dot{m}_{w1} \\ &= \dot{m}_a(\omega_2 - \omega_1) \\ &= (7.776 \text{ kg/min})(0.01619 - 0.009199) \\ &= \mathbf{0.0543 \text{ kg/min}} \end{aligned}$$

14-94 Air is cooled by an evaporative cooler. The final relative humidity and the amount of water added are to be determined.

Analysis (a) From the psychrometric chart (Fig. A-31) at 32°C and 30% relative humidity we read

$$T_{wb1} = 19.4^\circ\text{C}$$

$$\omega_1 = 0.0089 \text{ kg H}_2\text{O/kg dry air}$$

$$\nu_1 = 0.877 \text{ m}^3/\text{kg dry air}$$

Assuming the liquid water is supplied at a temperature not much different than the exit temperature of the air stream, the evaporative cooling process follows a line of constant wet-bulb temperature. That is,

$$T_{wb2} \cong T_{wb1} = 19.4^\circ\text{C}$$

At this wet-bulb temperature and 22°C temperature we read

$$\phi_2 = 79\%$$

$$\omega_2 = 0.0130 \text{ kg H}_2\text{O/kg dry air}$$

(b) The mass flow rate of dry air is

$$\dot{m}_a = \frac{\dot{V}_1}{\nu_1} = \frac{5 \text{ m}^3/\text{min}}{0.877 \text{ m}^3/\text{kg dry air}} = 5.70 \text{ kg/min}$$

Then the required rate of water supply to the evaporative cooler is determined from

$$\dot{m}_{\text{supply}} = \dot{m}_{w2} - \dot{m}_{w1} = \dot{m}_a(\omega_2 - \omega_1) = (5.70 \text{ kg/min})(0.0130 - 0.0089) = \mathbf{0.0234 \text{ kg/min}}$$

14-95 Air is first heated in a heating section and then passed through an evaporative cooler. The exit relative humidity and the amount of water added are to be determined.

Analysis (a) From the psychrometric chart (Fig. A-31 or EES) at 20°C and 50% relative humidity we read

$$\omega_1 = 0.00726 \text{ kg H}_2\text{O/kg dry air}$$

The specific humidity ω remains constant during the heating process. Therefore, $\omega_2 = \omega_1 = 0.00726 \text{ kg H}_2\text{O/kg dry air}$.

At this ω value and 35°C we read $T_{wb2} = 19.1^\circ\text{C}$.

Assuming the liquid water is supplied at a temperature not much different than the exit temperature of the air stream, the evaporative cooling process follows a line of constant wet-bulb temperature. That is, $T_{wb3} \cong T_{wb2} = 19.1^\circ\text{C}$. At this T_{wb} value and 25°C we read

$$\phi_3 = 57.5\%$$

$$\omega_3 = 0.0114 \text{ kg H}_2\text{O/kg dry air}$$

(b) The amount of water added to the air per unit mass of air is

$$\Delta\omega_{23} = \omega_3 - \omega_2 = 0.0114 - 0.00726 = \mathbf{0.00413 \text{ kg H}_2\text{O/kg dry air}}$$

Adiabatic Mixing of Airstreams

14-96C This will occur when the straight line connecting the states of the two streams on the psychrometric chart crosses the saturation line.

14-97C Yes.

14-98E Two airstreams are mixed steadily. The temperature, the specific humidity, and the relative humidity of the mixture are to be determined.

Assumptions **1** Steady operating conditions exist **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible. **4** The mixing section is adiabatic.

Properties The properties of each inlet stream are determined from the psychrometric chart (Fig. A-31E) to be

$$h_1 = 19.9 \text{ Btu/lbm dry air}$$

$$\omega_1 = 0.0039 \text{ lbm H}_2\text{O/lbm dry air}$$

$$\nu_1 = 13.30 \text{ ft}^3/\text{lbm dry air}$$

and

$$h_2 = 41.1 \text{ Btu/lbm dry air}$$

$$\omega_2 = 0.0200 \text{ lbm H}_2\text{O/lbm dry air}$$

$$\nu_2 = 14.04 \text{ ft}^3/\text{lbm dry air}$$

Analysis The mass flow rate of dry air in each stream is

$$\dot{m}_{a1} = \frac{\dot{V}_1}{\nu_1} = \frac{900 \text{ ft}^3/\text{min}}{13.30 \text{ ft}^3/\text{lbm dry air}} = 67.7 \text{ lbm/min}$$

$$\dot{m}_{a2} = \frac{\dot{V}_2}{\nu_2} = \frac{300 \text{ ft}^3/\text{min}}{14.04 \text{ ft}^3/\text{lbm dry air}} = 21.4 \text{ lbm/min}$$

The specific humidity and the enthalpy of the mixture can be determined from Eqs. 14-24, which are obtained by combining the conservation of mass and energy equations for the adiabatic mixing of two streams:

$$\frac{\dot{m}_{a1}}{\dot{m}_{a2}} = \frac{\omega_2 - \omega_3}{\omega_3 - \omega_1} = \frac{h_2 - h_3}{h_3 - h_1}$$

$$\frac{67.7}{21.4} = \frac{0.0200 - \omega_3}{\omega_3 - 0.0039} = \frac{41.1 - h_3}{h_3 - 19.9}$$

which yields,

$$(a) \quad \omega_3 = \mathbf{0.0078 \text{ lbm H}_2\text{O/lbm dry air}}$$

$$h_3 = 25.0 \text{ Btu/lbm dry air}$$

These two properties fix the state of the mixture. Other properties of the mixture are determined from the psychrometric chart:

$$(b) \quad T_3 = \mathbf{68.7^\circ\text{F}}$$

$$(c) \quad \phi_3 = \mathbf{52.1\%}$$

14-99E Problem 14-98E is reconsidered. A general solution of the problem in which the input variables may be supplied and parametric studies performed is to be developed and the process is to be shown in the psychrometric chart for each set of input variables.

Analysis The problem is solved using EES, and the solution is given below.

14-100 Two airstreams are mixed steadily. The specific humidity, the relative humidity, the dry-bulb temperature, and the volume flow rate of the mixture are to be determined.

Assumptions 1 Steady operating conditions exist 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible. 4 The mixing section is adiabatic.

Properties Properties of each inlet stream are determined from the psychrometric chart (Fig. A-31 or EES) to be

$$\begin{aligned}h_1 &= 62.28 \text{ kJ/kg dry air} \\ \omega_1 &= 0.01054 \text{ kg H}_2\text{O/kg dry air} \\ \nu_1 &= 0.8877 \text{ m}^3/\text{kg dry air}\end{aligned}$$

and

$$\begin{aligned}h_2 &= 31.88 \text{ kJ/kg dry air} \\ \omega_2 &= 0.007847 \text{ kg H}_2\text{O/kg dry air} \\ \nu_2 &= 0.8180 \text{ m}^3/\text{kg dry air}\end{aligned}$$

Analysis The mass flow rate of dry air in each stream is

$$\begin{aligned}\dot{m}_{a1} &= \frac{\dot{V}_1}{\nu_1} = \frac{15 \text{ m}^3/\text{min}}{0.8877 \text{ m}^3/\text{kg dry air}} = 16.90 \text{ kg/min} \\ \dot{m}_{a2} &= \frac{\dot{V}_2}{\nu_2} = \frac{25 \text{ m}^3/\text{min}}{0.8180 \text{ m}^3/\text{kg dry air}} = 30.56 \text{ kg/min}\end{aligned}$$

From the conservation of mass,

$$\dot{m}_{a3} = \dot{m}_{a1} + \dot{m}_{a2} = 16.90 + 30.56 = 47.46 \text{ kg/min}$$

The specific humidity and the enthalpy of the mixture can be determined from Eqs. 14-24, which are obtained by combining the conservation of mass and energy equations for the adiabatic mixing of two streams:

$$\begin{aligned}\frac{\dot{m}_{a1}}{\dot{m}_{a2}} &= \frac{\omega_2 - \omega_3}{\omega_3 - \omega_1} = \frac{h_2 - h_3}{h_3 - h_1} \\ \frac{16.90}{30.56} &= \frac{0.007847 - \omega_3}{\omega_3 - 0.01054} = \frac{31.88 - h_3}{h_3 - 62.28}\end{aligned}$$

which yields

$$\begin{aligned}h_3 &= 42.70 \text{ kJ/kg dry air} \\ \omega_3 &= \mathbf{0.0088 \text{ kg H}_2\text{O/kg dry air}}\end{aligned}$$

These two properties fix the state of the mixture. Other properties of the mixture are determined from the psychrometric chart:

$$\begin{aligned}T_3 &= \mathbf{20.2^\circ\text{C}} \\ \phi_3 &= \mathbf{59.7\%} \\ \nu_3 &= 0.8428 \text{ m}^3/\text{kg dry air}\end{aligned}$$

Finally, the volume flow rate of the mixture is determined from

$$\dot{V}_3 = \dot{m}_{a3} \nu_3 = (47.46 \text{ kg/min})(0.8428 \text{ m}^3/\text{kg dry air}) = \mathbf{40.0 \text{ m}^3/\text{min}}$$

14-101 Two airstreams are mixed steadily. The specific humidity, the relative humidity, the dry-bulb temperature, and the volume flow rate of the mixture are to be determined.

Assumptions 1 Steady operating conditions exist 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible. 4 The mixing section is adiabatic.

Analysis The properties of each inlet stream are determined to be

$$P_{v1} = \phi_1 P_{g1} = \phi_1 P_{\text{sat}@35^\circ\text{C}} = (0.30)(5.629 \text{ kPa}) = 1.689 \text{ kPa}$$

$$P_{a1} = P_1 - P_{v1} = 90 - 1.689 = 88.31 \text{ kPa}$$

$$\nu_1 = \frac{R_a T_1}{P_{a1}} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K})(308 \text{ K})}{88.31 \text{ kPa}}$$

$$= 1.001 \text{ m}^3 / \text{kg dry air}$$

$$\omega_1 = \frac{0.622 P_{v1}}{P_1 - P_{v1}} = \frac{0.622(1.689 \text{ kPa})}{(90 - 1.689) \text{ kPa}}$$

$$= 0.01189 \text{ kg H}_2\text{O/kg dry air}$$

$$h_1 = c_p T_1 + \omega_1 h_{g1}$$

$$= (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(35^\circ\text{C}) + (0.01189)(2564.6 \text{ kJ/kg})$$

$$= 65.68 \text{ kJ/kg dry air}$$

and

$$P_{v2} = \phi_2 P_{g2} = \phi_2 P_{\text{sat}@12^\circ\text{C}} = (0.90)(1.403 \text{ kPa}) = 1.262 \text{ kPa}$$

$$P_{a2} = P_2 - P_{v2} = 90 - 1.262 = 88.74 \text{ kPa}$$

$$\nu_2 = \frac{R_a T_2}{P_{a2}} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K})(285 \text{ K})}{88.74 \text{ kPa}} = 0.9218 \text{ m}^3 / \text{kg dry air}$$

$$\omega_2 = \frac{0.622 P_{v2}}{P_2 - P_{v2}} = \frac{0.622(1.262 \text{ kPa})}{(90 - 1.262) \text{ kPa}} = 0.008849 \text{ kg H}_2\text{O/kg dry air}$$

$$h_2 = c_p T_2 + \omega_2 h_{g2} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(12^\circ\text{C}) + (0.008849)(2522.9 \text{ kJ/kg}) = 34.39 \text{ kJ/kg dry air}$$

Then the mass flow rate of dry air in each stream is

$$\dot{m}_{a1} = \frac{\dot{V}_1}{\nu_1} = \frac{150 \text{ m}^3 / \text{min}}{1.001 \text{ m}^3 / \text{kg dry air}} = 14.99 \text{ kg/min}$$

$$\dot{m}_{a2} = \frac{\dot{V}_2}{\nu_2} = \frac{25 \text{ m}^3 / \text{min}}{0.9218 \text{ m}^3 / \text{kg dry air}} = 27.12 \text{ kg/min}$$

From the conservation of mass,

$$\dot{m}_{a3} = \dot{m}_{a1} + \dot{m}_{a2} = 14.99 + 27.12 = 42.11 \text{ kg/min}$$

The specific humidity and the enthalpy of the mixture can be determined from Eqs. 14-24, which are obtained by combining the conservation of mass and energy equations for the adiabatic mixing of two streams:

$$\frac{\dot{m}_{a1}}{\dot{m}_{a2}} = \frac{\omega_2 - \omega_3}{\omega_3 - \omega_1} = \frac{h_2 - h_3}{h_3 - h_1} \longrightarrow \frac{14.99}{27.12} = \frac{0.008849 - \omega_3}{\omega_3 - 0.01189} = \frac{34.39 - h_3}{h_3 - 65.68}$$

which yields

$$h_3 = 45.52 \text{ kJ/kg dry air}$$

$$\omega_3 = \mathbf{0.009933 \text{ kg H}_2\text{O/kg dry air}}$$

These two properties fix the state of the mixture. Other properties are determined from

$$h_3 = c_p T_3 + \omega_3 h_{g3} \cong c_p T_3 + \omega_3 (2501.3 + 1.82 T_3)$$

$$45.52 \text{ kJ/kg} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C}) T_3 + (0.009933)(2500.9 + 1.82 T_3) \text{ kJ/kg} \longrightarrow T_3 = \mathbf{20.2^\circ\text{C}}$$

$$\omega_3 = \frac{0.622 P_{v3}}{P_3 - P_{v3}}$$

$$0.009933 = \frac{0.622 P_{v3}}{90 - P_{v3}} \longrightarrow P_{v3} = 1.415 \text{ kPa}$$

$$\phi_3 = \frac{P_{v3}}{P_{g3}} = \frac{P_{v3}}{P_{\text{sat}@T_3}} = \frac{1.415 \text{ kPa}}{2.370 \text{ kPa}} = 0.597 \text{ or } \mathbf{59.7\%}$$

Finally,

$$P_{a3} = P_3 - P_{v3} = 90 - 1.415 = 88.59 \text{ kPa}$$

$$\nu_3 = \frac{R_a T_3}{P_{a3}} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K})(293.2 \text{ K})}{88.59 \text{ kPa}} = 0.9500 \text{ m}^3 / \text{kg dry air}$$

$$\dot{V}_3 = \dot{m}_{a3} \nu_3 = (42.11 \text{ kg/min})(0.9500 \text{ m}^3 / \text{kg}) = \mathbf{40.0 \text{ m}^3 / \text{min}}$$

14-102 A stream of warm air is mixed with a stream of saturated cool air. The temperature, the specific humidity, and the relative humidity of the mixture are to be determined.

Assumptions 1 Steady operating conditions exist 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible. 4 The mixing section is adiabatic.

Properties The properties of each inlet stream are determined from the psychrometric chart (Fig. A-31 or EES) to be

$$h_1 = 99.4 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.0246 \text{ kg H}_2\text{O/kg dry air}$$

and

$$h_2 = 34.1 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.00873 \text{ kg H}_2\text{O/kg dry air}$$

Analysis The specific humidity and the enthalpy of the mixture can be determined from Eqs. 14-24, which are obtained by combining the conservation of mass and energy equations for the adiabatic mixing of two streams:

$$\frac{\dot{m}_{a1}}{\dot{m}_{a2}} = \frac{\omega_2 - \omega_3}{\omega_3 - \omega_1} = \frac{h_2 - h_3}{h_3 - h_1}$$

$$\frac{8}{10} = \frac{0.00873 - \omega_3}{\omega_3 - 0.0246} = \frac{34.1 - h_3}{h_3 - 99.4}$$

which yields,

$$(b) \quad \omega_3 = \mathbf{0.0158 \text{ kg H}_2\text{O/kg dry air}}$$

$$h_3 = 63.1 \text{ kJ/kg dry air}$$

These two properties fix the state of the mixture. Other properties of the mixture are determined from the psychrometric chart:

$$(a) \quad T_3 = \mathbf{22.8^\circ\text{C}}$$

$$(c) \quad \phi_3 = \mathbf{90.1\%}$$

14-103 Problem 14-102 is reconsidered. The effect of the mass flow rate of saturated cool air stream on the mixture temperature, specific humidity, and relative humidity is to be investigated.

Analysis The problem is solved using EES, and the solution is given below.

14-104E Two airstreams are mixed steadily. The mass flow ratio of the two streams for a specified mixture relative humidity and the relative humidity of the mixture are to be determined.

Assumptions 1 Steady operating conditions exist 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible. 4 The mixing section is adiabatic.

Properties Properties of each inlet stream are determined from the psychrometric chart (Fig. A-31E or from EES) to be

$$h_1 = 20.3 \text{ Btu/lbmdry air}$$

$$\omega_1 = 0.0076 \text{ lbm H}_2\text{O/lbm dry air}$$

and

$$h_2 = 48.7 \text{ Btu/lbmdry air}$$

$$\omega_2 = 0.0246 \text{ lbm H}_2\text{O/lbm dry air}$$

Analysis An application of Eq. 14-24, which are obtained by combining the conservation of mass and energy equations for the adiabatic mixing of two streams gives

$$\frac{\dot{m}_{a1}}{\dot{m}_{a2}} = \frac{\omega_2 - \omega_3}{\omega_3 - \omega_1} = \frac{h_2 - h_3}{h_3 - h_1}$$

$$\frac{\dot{m}_{a1}}{\dot{m}_{a2}} = \frac{0.0246 - \omega_3}{\omega_3 - 0.0076} = \frac{48.7 - h_3}{h_3 - 20.3}$$

This equation cannot be solved directly. An iterative solution is needed. A mixture relative humidity ϕ_3 is selected. At this relative humidity and the given temperature (70°F), specific humidity and enthalpy are read from the psychrometric chart. These values are substituted into the above equation. If the equation is not satisfied, a new value of ϕ_3 is selected. This procedure is repeated until the equation is satisfied. Alternatively, EES software can be used. We used the following EES program to get these results:

$$\phi_3 = \mathbf{100\%}$$

$$\omega_3 = 0.0158 \text{ lbm H}_2\text{O/lbm dry air}$$

$$h_3 = 34.0 \text{ Btu/lbmdry air}$$

$$\frac{\dot{m}_{a1}}{\dot{m}_{a2}} = \mathbf{1.07}$$

"Given"

P=14.696 [psia]

Wet Cooling Towers

14-105C The working principle of a natural draft cooling tower is based on buoyancy. The air in the tower has a high moisture content, and thus is lighter than the outside air. This light moist air rises under the influence of buoyancy, inducing flow through the tower.

14-106C A spray pond cools the warm water by spraying it into the open atmosphere. They require 25 to 50 times the area of a wet cooling tower for the same cooling load.

14-107 Water is cooled by air in a cooling tower. The volume flow rate of air and the mass flow rate of the required makeup water are to be determined.

Assumptions 1 Steady operating conditions exist and thus mass flow rate of dry air remains constant during the entire process. 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible. 4 The cooling tower is adiabatic.

Analysis (a) The mass flow rate of dry air through the tower remains constant ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$), but the mass flow rate of liquid water decreases by an amount equal to the amount of water that vaporizes in the tower during the cooling process. The water lost through evaporation must be made up later in the cycle to maintain steady operation. Applying the mass and energy balances yields

Dry Air Mass Balance:

$$\sum \dot{m}_{a,i} = \sum \dot{m}_{a,e} \longrightarrow \dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$$

Water Mass Balance:

$$\begin{aligned} \sum \dot{m}_{w,i} &= \sum \dot{m}_{w,e} \longrightarrow \dot{m}_3 + \dot{m}_{a1}\omega_1 = \dot{m}_4 + \dot{m}_{a2}\omega_2 \\ \dot{m}_3 - \dot{m}_4 &= \dot{m}_a(\omega_2 - \omega_1) = \dot{m}_{\text{makeup}} \end{aligned}$$

Energy Balance:

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \stackrel{\text{no (steady)}}{=} 0 \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \quad \text{since } \dot{Q} = \dot{W} = 0 \\ 0 &= \sum \dot{m}_e h_e - \sum \dot{m}_i h_i \\ 0 &= \dot{m}_{a2} h_2 + \dot{m}_4 h_4 - \dot{m}_{a1} h_1 - \dot{m}_3 h_3 \\ 0 &= \dot{m}_a (h_2 - h_1) + (\dot{m}_3 - \dot{m}_{\text{makeup}}) h_4 - \dot{m}_3 h_3 \end{aligned}$$

Solving for \dot{m}_a ,

$$\dot{m}_a = \frac{\dot{m}_3(h_3 - h_4)}{(h_2 - h_1) - (\omega_2 - \omega_1)h_4}$$

From the psychrometric chart (Fig. A-31),

$$\begin{aligned} h_1 &= 49.9 \text{ kJ/kg dry air} \\ \omega_1 &= 0.0105 \text{ kg H}_2\text{O/kg dry air} \\ \nu_1 &= 0.853 \text{ m}^3/\text{kg dry air} \end{aligned}$$

and

$$\begin{aligned} h_2 &= 110.7 \text{ kJ/kg dry air} \\ \omega_2 &= 0.0307 \text{ kg H}_2\text{O/kg dry air} \end{aligned}$$

From Table A-4,

$$\begin{aligned} h_3 &\cong h_f @ 40^\circ\text{C} = 167.53 \text{ kJ/kg H}_2\text{O} \\ h_4 &\cong h_f @ 25^\circ\text{C} = 104.83 \text{ kJ/kg H}_2\text{O} \end{aligned}$$

Substituting,

$$\dot{m}_a = \frac{(90 \text{ kg/s})(167.53 - 104.83) \text{ kJ/kg}}{(110.7 - 49.9) \text{ kJ/kg} - (0.0307 - 0.0105)(104.83) \text{ kJ/kg}} = 96.2 \text{ kg/s}$$

Then the volume flow rate of air into the cooling tower becomes

$$\dot{V}_1 = \dot{m}_a \nu_1 = (96.2 \text{ kg/s})(0.854 \text{ m}^3/\text{kg}) = \mathbf{82.2 \text{ m}^3/\text{s}}$$

(b) The mass flow rate of the required makeup water is determined from

$$\dot{m}_{\text{makeup}} = \dot{m}_a(\omega_2 - \omega_1) = (96.2 \text{ kg/s})(0.0307 - 0.0105) = \mathbf{1.94 \text{ kg/s}}$$

14-108E Water is cooled by air in a cooling tower. The volume flow rate of air and the mass flow rate of the required makeup water are to be determined.

Assumptions 1 Steady operating conditions exist and thus mass flow rate of dry air remains constant during the entire process. 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible. 4 The cooling tower is adiabatic.

Analysis (a) The mass flow rate of dry air through the tower remains constant ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$), but the mass flow rate of liquid water decreases by an amount equal to the amount of water that vaporizes in the tower during the cooling process. The water lost through evaporation must be made up later in the cycle to maintain steady operation. Applying the mass balance and the energy balance equations yields

Dry Air Mass Balance:

$$\sum \dot{m}_{a,i} = \sum \dot{m}_{a,e} \longrightarrow \dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$$

Water Mass Balance:

$$\begin{aligned} \sum \dot{m}_{w,i} &= \sum \dot{m}_{w,e} \longrightarrow \dot{m}_3 + \dot{m}_{a1}\omega_1 = \dot{m}_4 + \dot{m}_{a2}\omega_2 \\ \dot{m}_3 - \dot{m}_4 &= \dot{m}_a(\omega_2 - \omega_1) = \dot{m}_{\text{makeup}} \end{aligned}$$

Energy Balance:

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \stackrel{\text{no (steady)}}{=} 0 \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \quad (\text{since } \dot{Q} = \dot{W} = 0) \\ 0 &= \sum \dot{m}_e h_e - \sum \dot{m}_i h_i \\ 0 &= \dot{m}_{a2} h_2 + \dot{m}_4 h_4 - \dot{m}_{a1} h_1 - \dot{m}_3 h_3 \\ 0 &= \dot{m}_a (h_2 - h_1) + (\dot{m}_3 - \dot{m}_{\text{makeup}}) h_4 - \dot{m}_3 h_3 \end{aligned}$$

Solving for \dot{m}_a ,

$$\dot{m}_a = \frac{\dot{m}_3(h_3 - h_4)}{(h_2 - h_1) - (\omega_2 - \omega_1)h_4}$$

From the psychrometric chart (Fig. A-31),

$$\begin{aligned} h_1 &= 30.9 \text{ Btu/lbm dry air} \\ \omega_1 &= 0.0115 \text{ lbm H}_2\text{O/lbm dry air} \\ \nu_1 &= 13.76 \text{ ft}^3/\text{lbm dry air} \end{aligned}$$

and

$$\begin{aligned} h_2 &= 63.2 \text{ Btu/lbm dry air} \\ \omega_2 &= 0.0366 \text{ lbm H}_2\text{O/lbm dry air} \end{aligned}$$

From Table A-4E,

$$\begin{aligned} h_3 &\cong h_f @ 110^\circ\text{F} = 78.02 \text{ Btu/lbm H}_2\text{O} \\ h_4 &\cong h_f @ 80^\circ\text{F} = 48.07 \text{ Btu/lbm H}_2\text{O} \end{aligned}$$

Substituting,

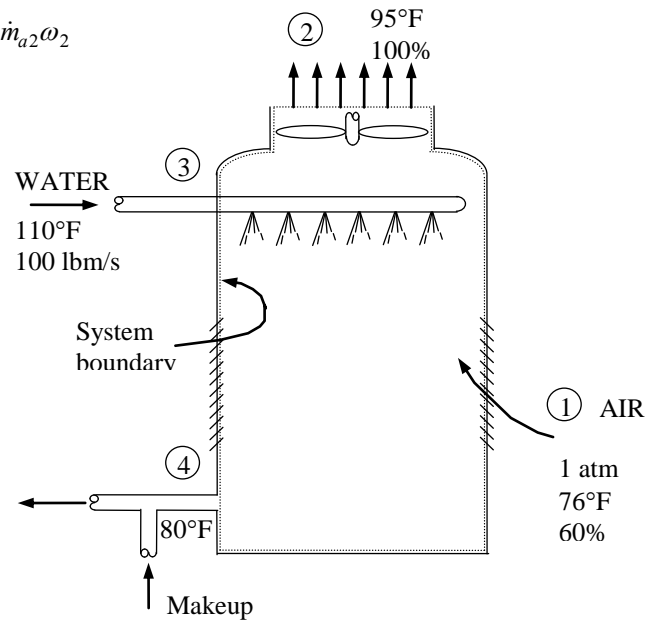

$$\dot{m}_a = \frac{(100 \text{ lbm/s})(78.02 - 48.07) \text{ Btu/lbm}}{(63.2 - 30.9) \text{ Btu/lbm} - (0.0366 - 0.0115)(48.07) \text{ Btu/lbm}} = 96.3 \text{ lbm/s}$$

Then the volume flow rate of air into the cooling tower becomes

$$\dot{V}_1 = \dot{m}_a \nu_1 = (96.3 \text{ lbm/s})(13.76 \text{ ft}^3/\text{lbm}) = \mathbf{1325 \text{ ft}^3/\text{s}}$$

(b) The mass flow rate of the required makeup water is determined from

$$\dot{m}_{\text{makeup}} = \dot{m}_a(\omega_2 - \omega_1) = (96.3 \text{ lbm/s})(0.0366 - 0.0115) = \mathbf{2.42 \text{ lbm/s}}$$

14-109 Water is cooled by air in a cooling tower. The volume flow rate of air and the mass flow rate of the required makeup water are to be determined.

Assumptions 1 Steady operating conditions exist and thus mass flow rate of dry air remains constant during the entire process. **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible. **4** The cooling tower is adiabatic.

Analysis (a) The mass flow rate of dry air through the tower remains constant ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$), but the mass flow rate of liquid water decreases by an amount equal to the amount of water that vaporizes in the tower during the cooling process. The water lost through evaporation must be made up later in the cycle to maintain steady operation. Applying the mass and energy balances yields

Dry Air Mass Balance:

$$\sum \dot{m}_{a,i} = \sum \dot{m}_{a,e} \longrightarrow \dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$$

Water Mass Balance:

$$\begin{aligned} \sum \dot{m}_{w,i} &= \sum \dot{m}_{w,e} \rightarrow \dot{m}_3 + \dot{m}_{a1}\omega_1 = \dot{m}_4 + \dot{m}_{a2}\omega_2 \\ \dot{m}_3 - \dot{m}_4 &= \dot{m}_a(\omega_2 - \omega_1) = \dot{m}_{\text{makeup}} \end{aligned}$$

Energy Balance:

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \stackrel{\approx 0 \text{ (steady)}}{=} 0 \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \quad (\text{since } \dot{Q} = \dot{W} = 0) \\ 0 &= \sum \dot{m}_e h_e - \sum \dot{m}_i h_i \\ 0 &= \dot{m}_{a2} h_2 + \dot{m}_4 h_4 - \dot{m}_{a1} h_1 - \dot{m}_3 h_3 \\ 0 &= \dot{m}_a (h_2 - h_1) + (\dot{m}_3 - \dot{m}_{\text{makeup}}) h_4 - \dot{m}_3 h_3 \end{aligned}$$

Solving for \dot{m}_a ,

$$\dot{m}_a = \frac{\dot{m}_3(h_3 - h_4)}{(h_2 - h_1) - (\omega_2 - \omega_1)h_4}$$

From the psychrometric chart (Fig. A-31 or EES),

$$\begin{aligned} h_1 &= 44.70 \text{ kJ/kg dry air} \\ \omega_1 &= 0.008875 \text{ kg H}_2\text{O/kg dry air} \\ \nu_1 &= 0.8480 \text{ m}^3/\text{kg dry air} \end{aligned}$$

and

$$\begin{aligned} h_2 &= 96.13 \text{ kJ/kg dry air} \\ \omega_2 &= 0.02579 \text{ kg H}_2\text{O/kg dry air} \end{aligned}$$

From Table A-4,

$$\begin{aligned} h_3 &\cong h_f @ 40^\circ\text{C} = 167.53 \text{ kJ/kg H}_2\text{O} \\ h_4 &\cong h_f @ 33^\circ\text{C} = 138.28 \text{ kJ/kg H}_2\text{O} \end{aligned}$$

Substituting,

$$\dot{m}_a = \frac{(60 \text{ kg/s})(167.53 - 138.28) \text{ kJ/kg}}{(96.13 - 44.70) \text{ kJ/kg} - (0.02579 - 0.008875)(138.28) \text{ kJ/kg}} = 35.76 \text{ kg/s}$$

Then the volume flow rate of air into the cooling tower becomes

$$\dot{V}_1 = \dot{m}_a \nu_1 = (35.76 \text{ kg/s})(0.8480 \text{ m}^3/\text{kg}) = \mathbf{30.3 \text{ m}^3/\text{s}}$$

(b) The mass flow rate of the required makeup water is determined from

$$\dot{m}_{\text{makeup}} = \dot{m}_a(\omega_2 - \omega_1) = (35.76 \text{ kg/s})(0.02579 - 0.008875) = \mathbf{0.605 \text{ kg/s}}$$

14-110 Water is cooled by air in a cooling tower. The volume flow rate of air and the mass flow rate of the required makeup water are to be determined.

Assumptions 1 Steady operating conditions exist and thus mass flow rate of dry air remains constant during the entire process. **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible. **4** The cooling tower is adiabatic.

Analysis (a) The mass flow rate of dry air through the tower remains constant ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$), but the mass flow rate of liquid water decreases by an amount equal to the amount of water that vaporizes in the tower during the cooling process. The water lost through evaporation must be made up later in the cycle to maintain steady operation. Applying the mass and energy balances yields

Dry Air Mass Balance:

$$\sum \dot{m}_{a,i} = \sum \dot{m}_{a,e} \longrightarrow \dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$$

Water Mass Balance:

$$\sum \dot{m}_{w,i} = \sum \dot{m}_{w,e}$$

$$\dot{m}_3 + \dot{m}_{a1}\omega_1 = \dot{m}_4 + \dot{m}_{a2}\omega_2$$

$$\dot{m}_3 - \dot{m}_4 = \dot{m}_a(\omega_2 - \omega_1) = \dot{m}_{\text{makeup}}$$

Energy Balance:

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\text{no (steady)}}{=} 0 \longrightarrow \dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \sum \dot{m}_e h_e \quad (\text{since } \dot{Q} = \dot{W} = 0)$$

$$0 = \sum \dot{m}_e h_e - \sum \dot{m}_i h_i$$

$$0 = \dot{m}_{a2}h_2 + \dot{m}_4h_4 - \dot{m}_{a1}h_1 - \dot{m}_3h_3$$

$$0 = \dot{m}_a(h_2 - h_1) + (\dot{m}_3 - \dot{m}_{\text{makeup}})h_4 - \dot{m}_3h_3$$

$$\dot{m}_a = \frac{\dot{m}_3(h_3 - h_4)}{(h_2 - h_1) - (\omega_2 - \omega_1)h_4}$$

The properties of air at the inlet and the exit are

$$P_{v1} = \phi_1 P_{g1} = \phi_1 P_{\text{sat}@20^\circ\text{C}} = (0.70)(2.3392 \text{ kPa}) = 1.637 \text{ kPa}$$

$$P_{a1} = P_1 - P_{v1} = 96 - 1.637 = 94.363 \text{ kPa}$$

$$v_1 = \frac{R_a T_1}{P_{a1}} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K})(293 \text{ K})}{94.363 \text{ kPa}} = 0.891 \text{ m}^3 / \text{kg dry air}$$

$$\omega_1 = \frac{0.622 P_{v1}}{P_1 - P_{v1}} = \frac{0.622(1.637 \text{ kPa})}{(96 - 1.637) \text{ kPa}} = 0.0108 \text{ kg H}_2\text{O/kg dry air}$$

$$h_1 = c_p T_1 + \omega_1 h_{g1} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(20^\circ\text{C}) + (0.0108)(2537.4 \text{ kJ/kg}) = 47.5 \text{ kJ/kg dry air}$$

and

$$P_{v2} = \phi_2 P_{g2} = \phi_2 P_{\text{sat}@35^\circ\text{C}} = (1.00)(5.6291 \text{ kPa}) = 5.6291 \text{ kPa}$$

$$\omega_2 = \frac{0.622 P_{v2}}{P_2 - P_{v2}} = \frac{0.622(5.6291 \text{ kPa})}{(96 - 5.6291) \text{ kPa}} = 0.0387 \text{ kg H}_2\text{O/kg dry air}$$

$$h_2 = c_p T_2 + \omega_2 h_{g2} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(35^\circ\text{C}) + (0.0387)(2564.6 \text{ kJ/kg}) = 134.4 \text{ kJ/kg dry air}$$

From Table A-4,

$$h_3 \cong h_f @ 40^\circ\text{C} = 167.53 \text{ kJ/kg H}_2\text{O}$$

$$h_4 \cong h_f @ 30^\circ\text{C} = 125.74 \text{ kJ/kg H}_2\text{O}$$

Substituting,

$$\dot{m}_a = \frac{(25 \text{ kg/s})(167.53 - 125.74) \text{ kJ/kg}}{(134.4 - 47.5) \text{ kJ/kg} - (0.0387 - 0.0108)(125.74) \text{ kJ/kg}} = 12.53 \text{ kg/s}$$

Then the volume flow rate of air into the cooling tower becomes

$$\dot{V}_1 = \dot{m}_a v_1 = (12.53 \text{ kg/s})(0.891 \text{ m}^3 / \text{kg}) = \mathbf{11.2 \text{ m}^3 / \text{s}}$$

(b) The mass flow rate of the required makeup water is determined from

$$\dot{m}_{\text{makeup}} = \dot{m}_a(\omega_2 - \omega_1) = (12.53 \text{ kg/s})(0.0387 - 0.0108) = \mathbf{0.35 \text{ kg/s}}$$

14-111E Water is cooled by air in a cooling tower. The mass flow rate of dry air is to be determined.

Assumptions 1 Steady operating conditions exist and thus mass flow rate of dry air remains constant during the entire process. 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible. 4 The cooling tower is adiabatic.

Analysis The mass flow rate of dry air through the tower remains constant ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$), but the mass flow rate of liquid water decreases by an amount equal to the amount of water that vaporizes in the tower during the cooling process. The water lost through evaporation must be made up later in the cycle to maintain steady operation. Applying the mass and energy balances yields

Dry Air Mass Balance:

$$\sum \dot{m}_{a,i} = \sum \dot{m}_{a,e} \longrightarrow \dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$$

Water Mass Balance:

$$\begin{aligned} \sum \dot{m}_{w,i} &= \sum \dot{m}_{w,e} \rightarrow \dot{m}_3 + \dot{m}_{a1}\omega_1 = \dot{m}_4 + \dot{m}_{a2}\omega_2 \\ \dot{m}_3 - \dot{m}_4 &= \dot{m}_a(\omega_2 - \omega_1) = \dot{m}_{\text{makeup}} \end{aligned}$$

Energy Balance:

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \stackrel{\text{no (steady)}}{=} 0 \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \quad (\text{since } \dot{Q} = \dot{W} = 0) \\ 0 &= \sum \dot{m}_e h_e - \sum \dot{m}_i h_i \\ 0 &= \dot{m}_{a2} h_2 + \dot{m}_4 h_4 - \dot{m}_{a1} h_1 - \dot{m}_3 h_3 \\ 0 &= \dot{m}_a (h_2 - h_1) + (\dot{m}_3 - \dot{m}_{\text{makeup}}) h_4 - \dot{m}_3 h_3 \end{aligned}$$

Solving for \dot{m}_a ,

$$\dot{m}_a = \frac{\dot{m}_3 (h_3 - h_4)}{(h_2 - h_1) - (\omega_2 - \omega_1) h_4}$$

From the psychrometric chart (Fig. A-31E),

$$\begin{aligned} h_1 &= 19.9 \text{ Btu/lbm dry air} \\ \omega_1 &= 0.00391 \text{ lbm H}_2\text{O/lbm dry air} \\ \nu_1 &= 13.31 \text{ ft}^3/\text{lbm dry air} \end{aligned}$$

and

$$\begin{aligned} h_2 &= 34.3 \text{ Btu/lbm dry air} \\ \omega_2 &= 0.0149 \text{ lbm H}_2\text{O/lbm dry air} \end{aligned}$$

From Table A-4E,

$$\begin{aligned} h_3 &\cong h_f @ 95^\circ\text{C} = 63.04 \text{ Btu/lbm H}_2\text{O} \\ h_4 &\cong h_f @ 80^\circ\text{C} = 48.07 \text{ Btu/lbm H}_2\text{O} \end{aligned}$$

Substituting,

$$\dot{m}_a = \frac{(3 \text{ lbm/s})(63.04 - 48.07) \text{ Btu/lbm}}{(34.3 - 19.9) \text{ Btu/lbm} - (0.0149 - 0.00391)(48.07) \text{ Btu/lbm}} = \mathbf{3.22 \text{ lbm/s}}$$

14-112E Water is cooled by air in a cooling tower. The exergy lost in the cooling tower is to be determined.

Assumptions 1 Steady operating conditions exist and thus mass flow rate of dry air remains constant during the entire process. 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible. 4 The cooling tower is adiabatic.

Analysis The mass flow rate of dry air through the tower remains constant ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$), but the mass flow rate of liquid water decreases by an amount equal to the amount of water that vaporizes in the tower during the cooling process. The water lost through evaporation must be made up later in the cycle to maintain steady operation. Applying the mass and energy balances yields

Dry Air Mass Balance:

$$\sum \dot{m}_{a,i} = \sum \dot{m}_{a,e} \longrightarrow \dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$$

Water Mass Balance:

$$\begin{aligned} \sum \dot{m}_{w,i} &= \sum \dot{m}_{w,e} \rightarrow \dot{m}_3 + \dot{m}_{a1}\omega_1 = \dot{m}_4 + \dot{m}_{a2}\omega_2 \\ \dot{m}_3 - \dot{m}_4 &= \dot{m}_a(\omega_2 - \omega_1) = \dot{m}_{\text{makeup}} \end{aligned}$$

Energy Balance:

$$\begin{aligned} \dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \stackrel{\text{no (steady)}}{=} 0 \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \quad (\text{since } \dot{Q} = \dot{W} = 0) \\ 0 &= \sum \dot{m}_e h_e - \sum \dot{m}_i h_i \\ 0 &= \dot{m}_{a2} h_2 + \dot{m}_4 h_4 - \dot{m}_{a1} h_1 - \dot{m}_3 h_3 \\ 0 &= \dot{m}_a (h_2 - h_1) + (\dot{m}_3 - \dot{m}_{\text{makeup}}) h_4 - \dot{m}_3 h_3 \end{aligned}$$

Solving for \dot{m}_a ,

$$\dot{m}_a = \frac{\dot{m}_3 (h_3 - h_4)}{(h_2 - h_1) - (\omega_2 - \omega_1) h_4}$$

From the psychrometric chart (Fig. A-31E),

$$\begin{aligned} h_1 &= 19.9 \text{ Btu/lbm dry air} \\ \omega_1 &= 0.00391 \text{ lbm H}_2\text{O/lbm dry air} \\ \nu_1 &= 13.31 \text{ ft}^3/\text{lbm dry air} \end{aligned}$$

and

$$\begin{aligned} h_2 &= 34.3 \text{ Btu/lbm dry air} \\ \omega_2 &= 0.0149 \text{ lbm H}_2\text{O/lbm dry air} \end{aligned}$$

From Table A-4,

$$\begin{aligned} h_3 &\cong h_f @ 95^\circ\text{F} = 63.04 \text{ Btu/lbm H}_2\text{O} \\ h_4 &\cong h_f @ 80^\circ\text{F} = 48.07 \text{ Btu/lbm H}_2\text{O} \end{aligned}$$

Substituting,

$$\dot{m}_a = \frac{(3 \text{ lbm/s})(63.04 - 48.07) \text{ Btu/lbm}}{(34.3 - 19.9) \text{ Btu/lbm} - (0.0149 - 0.00391)(48.07) \text{ Btu/lbm}} = 3.22 \text{ lbm/s}$$

The mass of water stream at state 3 per unit mass of dry air is

$$m_3 = \frac{\dot{m}_3}{\dot{m}_a} = \frac{3 \text{ lbm water/s}}{3.22 \text{ lbm dry air/s}} = 0.9317 \text{ lbm water/lbm dry air}$$

The mass flow rate of water stream at state 4 per unit mass of dry air is

$$m_4 = m_3 - (\omega_2 - \omega_1) = 0.9317 - (0.0149 - 0.00391) = 0.9207 \text{ lbm water/lbm dry air}$$

The entropies of water streams are

$$s_3 = s_f @ 95^\circ\text{F} = 0.12065 \text{ Btu/lbm} \cdot \text{R}$$

$$s_4 = s_f @ 80^\circ\text{F} = 0.09328 \text{ Btu/lbm} \cdot \text{R}$$

The entropy change of water stream is

$$\Delta s_{\text{water}} = m_4 s_4 - m_3 s_3 = 0.9207 \times 0.09328 - 0.9317 \times 0.12065 = -0.02653 \text{ Btu/R} \cdot \text{lbm dry air}$$

The entropies of water vapor in the air stream are

$$s_{g1} = s_g @ 65^\circ\text{F} = 2.0788 \text{ Btu/lbm} \cdot \text{R}$$

$$s_{g2} = s_g @ 80^\circ\text{F} = 2.0352 \text{ Btu/lbm} \cdot \text{R}$$

The entropy change of water vapor in the air stream is

$$\Delta s_{\text{vapor}} = \omega_2 s_{g2} - \omega_1 s_{g1} = 0.0149 \times 2.0352 - 0.00391 \times 2.0788 = 0.02220 \text{ Btu/R} \cdot \text{lbm dry air}$$

The partial pressures of water vapor and dry air for air streams are

$$P_{v1} = \phi_1 P_{g1} = \phi_1 P_{\text{sat} @ 65^\circ\text{F}} = (0.30)(0.30578 \text{ psia}) = 0.0917 \text{ psia}$$

$$P_{a1} = P_1 - P_{v1} = 14.696 - 0.0917 = 14.60 \text{ psia}$$

$$P_{v2} = \phi_2 P_{g2} = \phi_2 P_{\text{sat} @ 75^\circ\text{F}} = (0.80)(0.43016 \text{ psia}) = 0.3441 \text{ psia}$$

$$P_{a2} = P_2 - P_{v2} = 14.696 - 0.3441 = 14.35 \text{ psia}$$

The entropy change of dry air is

$$\begin{aligned} \Delta s_a &= s_2 - s_1 = c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_{a2}}{P_{a1}} \\ &= (0.240) \ln \frac{535}{525} - (0.06855) \ln \frac{14.35}{14.60} = 0.005712 \text{ Btu/lbm dry air} \end{aligned}$$

The entropy generation in the cooling tower is the total entropy change:

$$s_{\text{gen}} = \Delta s_{\text{water}} + \Delta s_{\text{vapor}} + \Delta s_a = -0.02653 + 0.02220 + 0.005712 = 0.001382 \text{ Btu/R} \cdot \text{lbm dry air}$$

Finally, the exergy destruction per unit mass of dry air is

$$x_{\text{dest}} = T_0 s_{\text{gen}} = (525 \text{ R})(0.001382 \text{ Btu/R} \cdot \text{lbm dry air}) = \mathbf{0.726 \text{ Btu/lbm dry air}}$$

Review Problems

14-113 Dry air flows over a water body at constant pressure and temperature until it is saturated. The molar analysis of the saturated air and the density of air before and after the process are to be determined.

Assumptions The air and the water vapor are ideal gases.

Properties The molar masses of N_2 , O_2 , Ar, and H_2O are 28.0, 32.0, 39.9 and 18 kg / kmol, respectively (Table A-1). The molar analysis of dry air is given to be 78.1 percent N_2 , 20.9 percent O_2 , and 1 percent Ar. The saturation pressure of water at 25°C is 3.1698 kPa (Table A-4). Also, 1 atm = 101.325 kPa.

Analysis (a) Noting that the total pressure remains constant at 101.32 kPa during this process, the partial pressure of air becomes

$$P = P_{\text{air}} + P_{\text{vapor}} \rightarrow P_{\text{air}} = P - P_{\text{vapor}} = 101.325 - 3.1698 = 98.155 \text{ kPa}$$

Then the molar analysis of the saturated air becomes

$$y_{H_2O} = \frac{P_{H_2O}}{P} = \frac{3.1698}{101.325} = \mathbf{0.0313}$$

$$y_{N_2} = \frac{P_{N_2}}{P} = \frac{y_{N_2,\text{dry}} P_{\text{dry air}}}{P} = \frac{0.781(98.155 \text{ kPa})}{101.325} = \mathbf{0.7566}$$

$$y_{O_2} = \frac{P_{O_2}}{P} = \frac{y_{O_2,\text{dry}} P_{\text{dry air}}}{P} = \frac{0.209(98.155 \text{ kPa})}{101.325} = \mathbf{0.2025}$$

$$y_{Ar} = \frac{P_{Ar}}{P} = \frac{y_{Ar,\text{dry}} P_{\text{dry air}}}{P} = \frac{0.01(98.155 \text{ kPa})}{101.325} = \mathbf{0.0097}$$

(b) The molar masses of dry and saturated air are

$$M_{\text{dry air}} = \sum y_i M_i = 0.781 \times 28.0 + 0.209 \times 32.0 + 0.01 \times 39.9 = 29.0 \text{ kg / kmol}$$

$$M_{\text{sat. air}} = \sum y_i M_i = 0.7566 \times 28.0 + 0.2025 \times 32.0 + 0.0097 \times 39.9 + 0.0313 \times 18 = 28.62 \text{ kg / kmol}$$

Then the densities of dry and saturated air are determined from the ideal gas relation to be

$$\rho_{\text{dry air}} = \frac{P}{(R_u / M_{\text{dry air}})T} = \frac{101.325 \text{ kPa}}{[(8.314 \text{ kPa} \cdot \text{m}^3 / \text{kmol} \cdot \text{K}) / 29.0 \text{ kg / kmol}](25 + 273) \text{ K}} = \mathbf{1.186 \text{ kg / m}^3}$$

$$\rho_{\text{sat. air}} = \frac{P}{(R_u / M_{\text{sat air}})T} = \frac{101.325 \text{ kPa}}{[(8.314 \text{ kPa} \cdot \text{m}^3 / \text{kmol} \cdot \text{K}) / 28.62 \text{ kg / kmol}](25 + 273) \text{ K}} = \mathbf{1.170 \text{ kg / m}^3}$$

Discussion We conclude that the density of saturated air is less than that of the dry air, as expected. This is due to the molar mass of water being less than that of dry air.

14-114E The error involved in assuming the density of air to remain constant during a humidification process is to be determined.

Properties The density of moist air before and after the humidification process is determined from the psychrometric chart (Fig. A-31E) to be

$$\left. \begin{array}{l} T_1 = 80^\circ\text{F} \\ \phi_1 = 25\% \end{array} \right\} \rho_{\text{air},1} = 0.0729 \text{ lbm/ft}^3$$

$$\left. \begin{array}{l} T_1 = 80^\circ\text{F} \\ \phi_1 = 75\% \end{array} \right\} \rho_{\text{air},2} = 0.0716 \text{ lbm/ft}^3$$

Analysis The error involved as a result of assuming constant air density is then determined to be

$$\% \text{Error} = \frac{\Delta \rho_{\text{air}}}{\rho_{\text{air},1}} \times 100 = \frac{(0.0729 - 0.0716) \text{ lbm/ft}^3}{0.0729 \text{ lbm/ft}^3} \times 100 = \mathbf{1.7\%}$$

which is acceptable for most engineering purposes.

14-115 Air is compressed by a compressor and then cooled to the ambient temperature at high pressure. It is to be determined if there will be any condensation in the compressed air lines.

Assumptions The air and the water vapor are ideal gases.

Properties The saturation pressure of water at 20°C is 2.3392 kPa (Table A-4)..

Analysis The vapor pressure of air before compression is

$$P_{v1} = \phi_1 P_g = \phi_1 P_{\text{sat}@25^\circ\text{C}} = (0.50)(2.3392 \text{ kPa}) = 1.17 \text{ kPa}$$

The pressure ratio during the compression process is $(800 \text{ kPa})/(92 \text{ kPa}) = 8.70$. That is, the pressure of air and any of its components increases by 8.70 times. Then the vapor pressure of air after compression becomes

$$P_{v2} = P_{v1} \times (\text{Pressure ratio}) = (1.17 \text{ kPa})(8.70) = 10.2 \text{ kPa}$$

The dew-point temperature of the air at this vapor pressure is

$$T_{\text{dp}} = T_{\text{sat}@P_{v2}} = T_{\text{sat}@10.2 \text{ kPa}} = 46.1^\circ\text{C}$$

which is greater than 20°C. Therefore, part of the moisture in the compressed air will **condense** when air is cooled to 20°C.

14-116E The required size of an evaporative cooler in cfm (ft^3/min) for an 8-ft high house is determined by multiplying the floor area of the house by 4. An equivalent rule is to be obtained in SI units.

Analysis Noting that $1 \text{ ft} = 0.3048 \text{ m}$ and thus $1 \text{ ft}^2 = 0.0929 \text{ m}^2$ and $1 \text{ ft}^3 = 0.0283 \text{ m}^3$, and noting that a flow rate of $4 \text{ ft}^3/\text{min}$ is required per ft^2 of floor area, the required flow rate in SI units per m^2 of floor area is determined to

$$1 \text{ ft}^2 \leftrightarrow 4 \text{ ft}^3 / \text{min}$$

$$0.0929 \text{ m}^2 \leftrightarrow 4 \times 0.0283 \text{ m}^3 / \text{min}$$

$$1 \text{ m}^2 \leftrightarrow 1.22 \text{ m}^3 / \text{min}$$

Therefore, a flow rate of **$1.22 \text{ m}^3/\text{min}$** is required per m^2 of floor area.

14-117 A cooling tower with a cooling capacity of 105 kW is claimed to evaporate 4000 kg of water per day. It is to be determined if this is a reasonable claim.

Assumptions 1 Water evaporates at an average temperature of 30°C . **2** The coefficient of performance of the air-conditioning unit is $\text{COP} = 3$.

Properties The enthalpy of vaporization of water at 30°C is 2429.8 kJ/kg (Table A-4).

Analysis Using the definition of COP, the electric power consumed by the air conditioning unit when running is

$$\dot{W}_{\text{in}} = \frac{\dot{Q}_{\text{cooling}}}{\text{COP}} = \frac{105 \text{ kW}}{3} = 35 \text{ kW}$$

Then the rate of heat rejected at the cooling tower becomes

$$\dot{Q}_{\text{rejected}} = \dot{Q}_{\text{cooling}} + \dot{W}_{\text{in}} = 105 + 35 = 140 \text{ kW}$$

Noting that 1 kg of water removes 2429.8 kJ of heat as it evaporates, the amount of water that needs to evaporate to remove heat at a rate of 140 kW is determined from $\dot{Q}_{\text{rejected}} = \dot{m}_{\text{water}} h_{fg}$ to be

$$\dot{m}_{\text{water}} = \frac{\dot{Q}_{\text{rejected}}}{h_{fg}} = \frac{140 \text{ kJ/s}}{2429.8 \text{ kJ/kg}} = 0.05762 \text{ kg/s} = 207.4 \text{ kg/h} = 4978 \text{ kg/day}$$

In practice, the air-conditioner will run intermittently rather than continuously at the rated power, and thus the water use will be less. Therefore, the claim amount of 4000 kg per day is **reasonable**.

14-118 Shading the condenser can reduce the air-conditioning costs by up to 10 percent. The amount of money shading can save a homeowner per year during its lifetime is to be determined.

Assumptions It is given that the annual air-conditioning cost is \$500 a year, and the life of the air-conditioning system is 20 years.

Analysis The amount of money that would be saved per year is determined directly from

$$(\$500/\text{year})(20 \text{ years})(0.10) = \mathbf{\$1000}$$

Therefore, the proposed measure will save about \$1000 during the lifetime of the system.

14-119E Wearing heavy long-sleeved sweaters and reducing the thermostat setting 1°F reduces the heating cost of a house by 4 percent at a particular location. The amount of money saved per year by lowering the thermostat setting by 4°F is to be determined.

Assumptions The household is willing to wear heavy long-sleeved sweaters in the house, and the annual heating cost is given to be \$600 a year.

Analysis The amount of money that would be saved per year is determined directly from

$$(\$600/\text{year})(0.04/^\circ\text{F})(4^\circ\text{F}) = \mathbf{\$96/\text{year}}$$

Therefore, the proposed measure will save the homeowner about \$100 during a heating season..

14-120 Air at a specified state is heated to to a specified temperature. The relative humidity after the heating is to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis The properties of the air at the ambient state are determined from the psychrometric chart (Figure A-31) to be

$$\omega_1 = 0.0015 \text{ kg H}_2\text{O/kg dry air} (= \omega_2)$$

As the outside air infiltrates into the dacha, it does not gain or lose any water. Therefore the humidity ratio inside the dacha is the same as that outside,

$$\omega_2 = \omega_1 = 0.0015 \text{ kg H}_2\text{O/kg dry air}$$

Entering the psychrometry chart at this humidity ratio and the temperature inside the dacha gives

$$\phi_2 = 0.1184 \text{ or } \mathbf{11.8\%}$$

14-121 Air is humidified by evaporating water into this air. The amount of heating per m^3 of air is to be determined.

Assumptions **1** This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Properties The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at various states are determined from the psychrometric chart (Figure A-31 or EES) to be

$$h_1 = 21.93 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.001504 \text{ kg H}_2\text{O/kg dry air}$$

$$\nu_1 = 0.8268 \text{ m}^3/\text{kg dry air}$$

and

$$h_2 = 34.34 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.006401 \text{ kg H}_2\text{O/kg dry air}$$

Also,

$$h_w \cong h_f @ 20^\circ\text{C} = 83.915 \text{ kJ/kg} \quad (\text{Table A-4})$$

Analysis The amount of moisture in the air increases due to humidification ($\omega_2 > \omega_1$). Applying the water mass balance and energy balance equations to the combined cooling and humidification section,

Water Mass Balance:

$$\sum \dot{m}_{w,i} = \sum \dot{m}_{w,e} \longrightarrow \dot{m}_{a1}\omega_1 = \dot{m}_{a2}\omega_2 + \dot{m}_w$$

Energy Balance:

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\text{0 (steady)}}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i + \dot{Q}_{\text{in}} = \sum \dot{m}_e h_e$$

$$\dot{Q}_{\text{in}} = \dot{m}_{a2}h_2 - \dot{m}_{a1}h_1 - \dot{m}_w h_w = \dot{m}_a (h_2 - h_1) - \dot{m}_w h_w$$

$$q_{\text{in}} = h_2 - h_1 - (\omega_2 - \omega_1)h_w$$

$$= (34.34 - 21.93) \text{ kJ/kg} - (0.006401 - 0.001504)(83.915)$$

$$= 12.00 \text{ kJ/kg dry air}$$

The heat transfer per unit volume is

$$Q_{\text{in}} = \frac{q_{\text{in}}}{\nu_1} = \frac{12.00 \text{ kJ/kg dry air}}{0.8268 \text{ m}^3/\text{kg dry air}} = \mathbf{14.5 \text{ kJ/m}^3}$$

14-122E Air is cooled by evaporating water into this air. The amount of water required and the cooling produced are to be determined.

Assumptions **1** This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Properties The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at various states are determined from the psychrometric chart (Figure A-31E) to be

$$h_1 = 35.6 \text{ Btu/lbm dry air}$$

$$\omega_1 = 0.0082 \text{ lbm H}_2\text{O/lbm dry air}$$

and

$$h_2 = 34.3 \text{ Btu/lbm dry air}$$

$$\omega_2 = 0.0149 \text{ lbm H}_2\text{O/lbm dry air}$$

Also,

$$h_w \cong h_f @ 70^\circ\text{F} = 38.08 \text{ Btu/lbm} \quad (\text{Table A-4E})$$

Analysis The amount of moisture in the air increases due to humidification ($\omega_2 > \omega_1$). Applying the water mass balance and energy balance equations to the combined cooling and humidification section,

Water Mass Balance:

$$\sum \dot{m}_{w,i} = \sum \dot{m}_{w,e} \longrightarrow \dot{m}_{a1}\omega_1 = \dot{m}_{a2}\omega_2 + \dot{m}_w$$

$$\Delta\omega = \omega_2 - \omega_1 = 0.0149 - 0.0082 = \mathbf{0.0067 \text{ lbm H}_2\text{O/klbm dry air}}$$

Energy Balance:

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta\dot{E}_{\text{system}} \overset{\phi^0(\text{steady})}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \dot{Q}_{\text{out}} + \sum \dot{m}_e h_e$$

$$\dot{Q}_{\text{out}} = \dot{m}_a h_1 + \dot{m}_w h_w - \dot{m}_a h_2 = \dot{m}_a (h_1 - h_2) + \dot{m}_w h_w$$

$$q_{\text{out}} = h_1 - h_2 + (\omega_2 - \omega_1)h_w$$

$$= (35.6 - 34.3)\text{Btu/lbm} + (0.0067)(38.08)$$

$$= \mathbf{1.47 \text{ Btu/lbm dry air}}$$

14-123E Air is humidified adiabatically by evaporating water into this air. The temperature of the air at the exit is to be determined.

Assumptions **1** This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Properties The inlet state of the air is completely specified, and the total pressure is 1 atm. The properties of the air at the inlet state are determined from the psychrometric chart (Figure A-31E) to be

$$h_1 = 35.6 \text{ Btu/lbmdry air}$$

$$\omega_1 = 0.0082 \text{ lbm H}_2\text{O/lbm dry air}$$

and $h_w \cong h_f @ 70^\circ\text{F} = 38.08 \text{ Btu/lbm}$ (Table A-4E)

Analysis The amount of moisture in the air increases due to humidification ($\omega_2 > \omega_1$). Applying the water mass balance and energy balance equations to the combined cooling and humidification section,

Water Mass Balance:

$$\begin{aligned} \sum \dot{m}_{w,i} &= \sum \dot{m}_{w,e} \longrightarrow \dot{m}_{a1}\omega_1 = \dot{m}_{a2}\omega_2 + \dot{m}_w \\ \dot{m}_w &= \dot{m}_a(\omega_2 - \omega_1) \end{aligned}$$

Energy Balance:

$$\begin{aligned} \dot{E}_{in} - \dot{E}_{out} &= \Delta \dot{E}_{system} \stackrel{\text{0 (steady)}}{=} 0 \\ \dot{E}_{in} &= \dot{E}_{out} \\ \sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \\ \dot{m}_{a1}h_1 + \dot{m}_w h_w &= \dot{m}_{a2}h_2 \\ \dot{m}_w h_w &= \dot{m}_a(h_2 - h_1) \\ (\omega_2 - \omega_1)h_w &= h_2 - h_1 \end{aligned}$$

Substituting,

$$(\omega_2 - 0.0092)(83.92) = h_2 - 64.0$$

The solution of this equation requires a trial-error method. An air exit temperature is assumed. At this temperature and the given relative humidity, the enthalpy and specific humidity values are obtained from psychrometric chart and substituted into this equation. If the equation is not satisfied, a new value of exit temperature is assumed and this continues until the equation is satisfied. Alternatively, an equation solver such as EES may be used for the direct results. We used the following EES program to get these results:

$$T_2 = \mathbf{79.6^\circ\text{F}}$$

$$h_2 = 35.8 \text{ Btu/lbmdry air}$$

$$\omega_2 = 0.0152 \text{ lbm H}_2\text{O/lbm dry air}$$

"Given"

$$P=14.696 \text{ [psia]}$$

$$T_1=110 \text{ [F]}$$

$$\text{phi}_1=0.15$$

$$\text{phi}_2=0.70$$

$$T_w=70 \text{ [F]}$$

"Analysis"

$$\text{Fluid1\$}=\text{'AirH2O'}$$

$$\text{Fluid2\$}=\text{'steam_iapws'}$$

$$h_1=\text{enthalpy}(\text{Fluid1\$}, T=T_1, R=\text{phi}_1, P=P)$$

$$w_1=\text{humrat}(\text{Fluid1\$}, T=T_1, R=\text{phi}_1, P=P)$$

$$h_2=\text{enthalpy}(\text{Fluid1\$}, T=T_2, R=\text{phi}_2, P=P)$$

$$w_2=\text{humrat}(\text{Fluid1\$}, T=T_2, R=\text{phi}_2, P=P)$$

$$h_w=\text{enthalpy}(\text{Fluid2\$}, T=T_w, x=0)$$

$$q=0$$

$$q=h_1-h_2+(w_2-w_1)*h_w$$

14-124 A tank contains saturated air at a specified state. The mass of the dry air, the specific humidity, and the enthalpy of the air are to be determined.

Assumptions The air and the water vapor are ideal gases.

Analysis (a) The air is saturated, thus the partial pressure of water vapor is equal to the saturation pressure at the given temperature,

$$P_v = P_g = P_{\text{sat @ } 20^\circ\text{C}} = 2.339 \text{ kPa}$$

$$P_a = P - P_v = 90 - 2.339 = 87.66 \text{ kPa}$$

Treating air as an ideal gas,

$$m_a = \frac{P_a V}{R_a T} = \frac{(87.66 \text{ kPa})(1.8 \text{ m}^3)}{(0.287 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K})(293 \text{ K})} = \mathbf{1.88 \text{ kg}}$$

<p>1.8 m³ 20°C 90 kPa</p>
--

(b) The specific humidity of air is determined from

$$\omega = \frac{0.622 P_v}{P - P_v} = \frac{(0.622)(2.339 \text{ kPa})}{(90 - 2.339) \text{ kPa}} = \mathbf{0.0166 \text{ kg H}_2\text{O/kg dry air}}$$

(c) The enthalpy of air per unit mass of dry air is determined from

$$\begin{aligned} h &= h_a + \omega h_v \cong c_p T + \omega h_g \\ &= (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(20^\circ\text{C}) + (0.0166)(2537.4 \text{ kJ/kg}) \\ &= \mathbf{62.2 \text{ kJ/kg dry air}} \end{aligned}$$

14-125 Problem 14-124 is reconsidered. The properties of the air at the initial state are to be determined and the effects of heating the air at constant volume until the pressure is 110 kPa is to be studied.

Analysis The problem is solved using EES, and the solution is given below.

"Input Data:"

Tdb[1] = 20 [C]
 P[1]=90 [kPa]
 Rh[1]=1.0
 P[2]=110 [kPa]
 Vol = 1.8 [m^3]

w[1]=HUMRAT(AirH2O,T=Tdb[1],P=P[1],R=Rh[1])
 v[1]=VOLUME(AirH2O,T=Tdb[1],P=P[1],R=Rh[1])
 m_a=Vol/v[1]
 h[1]=ENTHALPY(AirH2O,T=Tdb[1],P=P[1],w=w[1])

"Energy Balance for the constant volume tank:"

E_in - E_out = DELTAE_tank
 DELTAE_tank=m_a*(u[2]-u[1])
 E_in = Q_in
 E_out = 0 [kJ]
 u[1]=INTENERGY(AirH2O,T=Tdb[1],P=P[1],w=w[1])
 u[2]=INTENERGY(AirH2O,T=Tdb[2],P=P[2],w=w[2])

"The ideal gas mixture assumption applied to the constant volume process yields:"

$P[1]/(Tdb[1]+273)=P[2]/(Tdb[2]+273)$

"The mass of the water vapor and dry air are constant, thus:"

w[2]=w[1]
 Rh[2]=RELHUM(AirH2O,T=Tdb[2],P=P[2],w=w[2])
 h[2]=ENTHALPY(AirH2O,T=Tdb[2],P=P[2],w=w[2])
 v[2]=VOLUME(AirH2O,T=Tdb[2],P=P[2],R=Rh[2])

PROPERTIES AT THE INITIAL STATE

h[1]=62.25 [kJ/kg]
 m_a=1.875 [kga]
 v[1]=0.9599 [m^3/kga]
 w[1]=0.01659 [kgw/kga]

P ₂ [kPa]	Q _{in} [kJ]
90	0
92	9.071
94	18.14
96	27.22
98	36.29
100	45.37
102	54.44
104	63.52
106	72.61
108	81.69
110	90.78

14-126E Air at a specified state and relative humidity flows through a circular duct. The dew-point temperature, the volume flow rate of air, and the mass flow rate of dry air are to be determined.

Assumptions The air and the water vapor are ideal gases.

Analysis (a) The vapor pressure of air is

$$P_v = \phi P_g = \phi P_{\text{sat}@60^\circ\text{F}} = (0.70)(0.2564 \text{ psia}) = 0.1795 \text{ psia}$$

Thus the dew-point temperature of the air is

$$T_{\text{dp}} = T_{\text{sat}@P_v} = T_{\text{sat}@0.1795 \text{ psia}} = \mathbf{50.2^\circ\text{F}} \quad (\text{from EES})$$

(b) The volume flow rate is determined from

$$\dot{V} = VA = V \frac{\pi D^2}{4} = (35 \text{ ft/s}) \left(\frac{\pi \times (6/12 \text{ ft})^2}{4} \right) = \mathbf{6.872 \text{ ft}^3/\text{s}}$$

(c) To determine the mass flow rate of dry air, we first need to calculate its specific volume,

$$P_a = P - P_v = 15 - 0.1795 = 14.82 \text{ psia}$$

$$\nu_1 = \frac{R_a T_1}{P_{a1}} = \frac{(0.3704 \text{ psia} \cdot \text{ft}^3 / \text{lbm} \cdot \text{R})(520 \text{ R})}{14.82 \text{ psia}} = 13.00 \text{ ft}^3 / \text{lbm dry air}$$

Thus,

$$\dot{m}_{a1} = \frac{\dot{V}_1}{\nu_1} = \frac{6.872 \text{ ft}^3 / \text{s}}{13.00 \text{ ft}^3 / \text{lbm dry air}} = \mathbf{0.529 \text{ lbm/s}}$$

14-127 Air flows steadily through an isentropic nozzle. The pressure, temperature, and velocity of the air at the nozzle exit are to be determined.

Assumptions **1** This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis The inlet state of the air is completely specified, and the total pressure is 200 kPa. The properties of the air at the inlet state may be determined from the psychrometric chart (Figure A-31) or using EES psychrometric functions to be (we used EES)

$$h_1 = 57.65 \text{ kJ/kg dry air}$$

$$\omega_1 = \omega_2 = 0.008803 \text{ kg H}_2\text{O/kg dry air} \quad (\text{no condensation})$$

$$s_1 = s_2 = 5.613 \text{ kJ/kg}\cdot\text{K dry air} \quad (\text{isentropic process})$$

We assume that the relative humidity at the nozzle exit is 100 percent since there is no condensation in the nozzle. Other exit state properties can be determined using EES built-in functions for moist air. The results are

$$h_2 = 42.53 \text{ kJ/kg dry air}$$

$$P_2 = \mathbf{168.2 \text{ kPa}}$$

$$T_2 = \mathbf{20^\circ\text{C}}$$

An energy balance on the control volume gives the velocity at the exit

$$h_1 = h_2 + (1 + \omega_2) \frac{V_2^2}{2}$$

$$57.65 \text{ kJ/kg} = 42.53 \text{ kJ/kg} + (1 + 0.008803) \frac{V_2^2}{2} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right)$$

$$V_2 = \mathbf{173.2 \text{ m/s}}$$

14-128 Air enters a cooling section at a specified pressure, temperature, and relative humidity. The temperature of the air at the exit and the rate of heat transfer are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis (a) The amount of moisture in the air also remains constant ($\omega_1 = \omega_2$) as it flows through the cooling section since the process involves no humidification or dehumidification. The total pressure is 97 kPa. The properties of the air at the inlet state are

$$P_{v1} = \phi_1 P_{g1} = \phi_1 P_{\text{sat}@35^\circ\text{C}} = (0.3)(5.629 \text{ kPa}) = 1.69 \text{ kPa}$$

$$P_{a1} = P_1 - P_{v1} = 97 - 1.69 = 95.31 \text{ kPa}$$

$$\begin{aligned} \nu_1 &= \frac{R_a T_1}{P_{a1}} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K})(308 \text{ K})}{95.31 \text{ kPa}} \\ &= 0.927 \text{ m}^3 / \text{kg dry air} \end{aligned}$$

$$\omega_1 = \frac{0.622 P_{v1}}{P_1 - P_{v1}} = \frac{0.622(1.69 \text{ kPa})}{(97 - 1.69) \text{ kPa}} = 0.0110 \text{ kg H}_2\text{O/kg dry air} (= \omega_2)$$

$$h_1 = c_p T_1 + \omega_1 h_{g1} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(35^\circ\text{C}) + (0.0110)(2564.6 \text{ kJ/kg}) = 63.44 \text{ kJ/kg dry air}$$

The air at the final state is saturated and the vapor pressure during this process remains constant. Therefore, the exit temperature of the air must be the dew-point temperature,

$$T_{\text{dp}} = T_{\text{sat}@P_v} = T_{\text{sat}@1.69 \text{ kPa}} = \mathbf{14.8^\circ\text{C}}$$

(b) The enthalpy of the air at the exit is

$$h_2 = c_p T_2 + \omega_2 h_{g2} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(14.8^\circ\text{C}) + (0.0110)(2528.1 \text{ kJ/kg}) = 42.78 \text{ kJ/kg dry air}$$

Also

$$\dot{m}_a = \frac{\dot{V}_1}{\nu_1} = \frac{6 \text{ m}^3 / \text{s}}{0.927 \text{ m}^3 / \text{kg dry air}} = 6.47 \text{ kg/min}$$

Then the rate of heat transfer from the air in the cooling section becomes

$$\dot{Q}_{\text{out}} = \dot{m}_a (h_1 - h_2) = (6.47 \text{ kg/min})(63.44 - 42.78) \text{ kJ/kg} = \mathbf{134 \text{ kJ/min}}$$

14-129 The outdoor air is first heated and then humidified by hot steam in an air-conditioning system. The rate of heat supply in the heating section and the mass flow rate of the steam required in the humidifying section are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Properties The amount of moisture in the air also remains constant as it flows through the heating section ($\omega_1 = \omega_2$), but increases in the humidifying section ($\omega_3 > \omega_2$). The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. The properties of the air at various states are determined from the psychrometric chart (Fig. A-31) to be

$$\begin{aligned} h_1 &= 23.47 \text{ kJ/kg dry air} \\ \omega_1 &= 0.005322 \text{ kg H}_2\text{O/kg dry air} (= \omega_2) \\ \nu_1 &= 0.8090 \text{ m}^3/\text{kg dry air} \\ h_2 &= 31.60 \text{ kJ/kg dry air} \\ \omega_2 &= \omega_1 = 0.005322 \text{ kg H}_2\text{O/kg dry air} \\ h_3 &= 52.90 \text{ kJ/kg dry air} \\ \omega_3 &= 0.01089 \text{ kg H}_2\text{O/kg dry air} \end{aligned}$$

Analysis (a) The mass flow rate of dry air is

$$\dot{m}_a = \frac{\dot{V}_1}{\nu_1} = \frac{26 \text{ m}^3/\text{min}}{0.8090 \text{ m}^3/\text{kg}} = 32.14 \text{ kg/min}$$

Then the rate of heat transfer to the air in the heating section becomes

$$\dot{Q}_{\text{in}} = \dot{m}_a (h_2 - h_1) = (32.14 \text{ kg/min})(31.60 - 23.47) \text{ kJ/kg} = \mathbf{261 \text{ kJ/min}}$$

(b) The conservation of mass equation for water in the humidifying section can be expressed as

$$\dot{m}_{a2}\omega_2 + \dot{m}_w = \dot{m}_{a3}\omega_3 \quad \text{or} \quad \dot{m}_w = \dot{m}_a(\omega_3 - \omega_2)$$

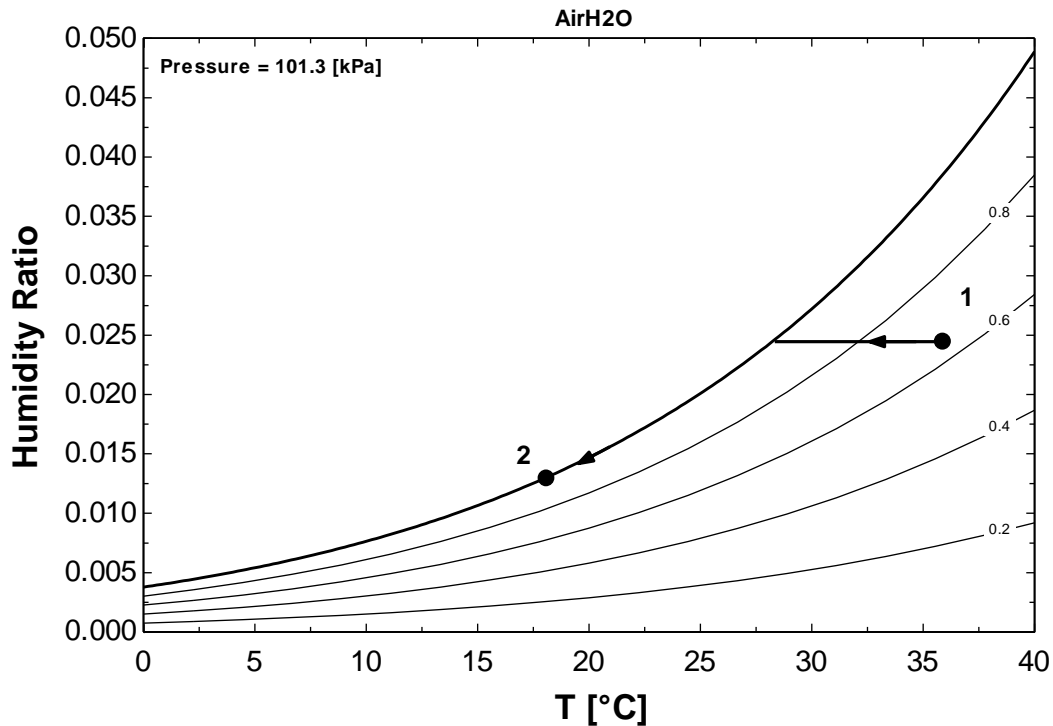

Thus,

$$\dot{m}_w = (32.14 \text{ kg/min})(0.01089 - 0.005322) = \mathbf{0.179 \text{ kg/min}}$$

14-130 Air is cooled and dehumidified at constant pressure. The system hardware and the psychrometric diagram are to be sketched and the heat transfer is to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Properties (a) The schematic of the cooling and dehumidification process and the process on the psychrometric chart are given below. The psychrometric chart is obtained from the Property Plot feature of EES.

(b) The inlet and the exit states of the air are completely specified, and the total pressure is 101.3 kPa (1 atm). The properties of the air at the inlet and exit states are determined from the psychrometric chart (Figure A-31 or EES, we used EES.) to be

$$T_{dp} = 28.37^\circ\text{C}$$

$$h_1 = 99.60 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.02467 \text{ kg H}_2\text{O/kg dry air}$$

and

$$T_2 = T_{dp} - 10 = 28.37 - 10 = 18.37^\circ\text{C}$$

$$\phi_2 = 1.0$$

$$h_2 = 52.09 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.01324 \text{ kg H}_2\text{O/kg dry air}$$

Also,

$$h_w \cong h_f @ 18.37^\circ\text{C} = 77.11 \text{ kJ/kg} \quad (\text{Table A-4})$$

Analysis Applying the water mass balance and energy balance equations to the combined cooling and dehumidification section,

Water Mass Balance:

$$\sum \dot{m}_{w,i} = \sum \dot{m}_{w,e} \longrightarrow \dot{m}_{a1}\omega_1 = \dot{m}_{a2}\omega_2 + \dot{m}_w$$

$$\dot{m}_w = \dot{m}_a(\omega_1 - \omega_2)$$

Energy Balance:

$$\begin{aligned}\dot{E}_{\text{in}} - \dot{E}_{\text{out}} &= \Delta \dot{E}_{\text{system}} \stackrel{\phi^0(\text{steady})}{=} 0 \\ \dot{E}_{\text{in}} &= \dot{E}_{\text{out}} \\ \sum \dot{m}_i h_i &= \dot{Q}_{\text{out}} + \sum \dot{m}_e h_e \\ \dot{Q}_{\text{out}} &= \dot{m}_{a1} h_1 - (\dot{m}_{a2} h_2 + \dot{m}_w h_w) \\ &= \dot{m}_a (h_1 - h_2) - \dot{m}_w h_w \\ &= \dot{m}_a (h_1 - h_2) - \dot{m}_a (\omega_1 - \omega_2) h_w\end{aligned}$$

Dividing by \dot{m}_a

$$q_{\text{out}} = (h_1 - h_2) - (\omega_1 - \omega_2) h_w$$

Substituting,

$$q_{\text{out}} = (h_1 - h_2) - (\omega_1 - \omega_2) h_w = (99.60 - 52.09) \text{ kJ/kg} - (0.02467 - 0.01324)(77.11 \text{ kJ/kg}) = \mathbf{46.6 \text{ kJ/kg}}$$

14-131 Air is cooled and dehumidified in an air-conditioning system with refrigerant-134a as the working fluid. The rate of dehumidification, the rate of heat transfer, and the mass flow rate of the refrigerant are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis (a) The saturation pressure of water at 30°C is 4.2469 kPa. Then the dew point temperature of the incoming air stream at 30°C becomes

$$T_{dp} = T_{sat @ P_v} = T_{sat @ 0.7 \times 4.2469 \text{ kPa}} = 24^\circ\text{C}$$

Since air is cooled to 20°C, which is below its dew point temperature, some of the moisture in the air will condense.

The mass flow rate of dry air remains constant during the entire process, but the amount of moisture in the air decreases due to dehumidification ($\omega_2 < \omega_1$). The inlet and the exit states of the air are completely specified, and the total pressure is 1 atm. Then the properties of the air at both states are determined from the psychrometric chart (Fig. A-31) to be

$$h_1 = 78.3 \text{ kJ/kg dry air}$$

$$\omega_1 = 0.0188 \text{ kg H}_2\text{O/kg dry air}$$

$$\nu_1 = 0.885 \text{ m}^3/\text{kg dry air}$$

and

$$h_2 = 57.5 \text{ kJ/kg dry air}$$

$$\omega_2 = 0.0147 \text{ kg H}_2\text{O/kg dry air}$$

Also, $h_w \cong h_f @ 20^\circ\text{C} = 83.915 \text{ kJ/kg}$ (Table A-4)

$$\text{Then, } \dot{m}_{a1} = \frac{\dot{V}_1}{\nu_1} = \frac{4 \text{ m}^3/\text{min}}{0.885 \text{ m}^3/\text{kg dry air}} = 4.52 \text{ kg/min}$$

Applying the water mass balance and the energy balance equations to the combined cooling and dehumidification section (excluding the refrigerant),

Water Mass Balance:

$$\sum \dot{m}_{w,i} = \sum \dot{m}_{w,e} \quad \longrightarrow \quad \dot{m}_{a1}\omega_1 = \dot{m}_{a2}\omega_2 + \dot{m}_w$$

$$\dot{m}_w = \dot{m}_a(\omega_1 - \omega_2) = (4.52 \text{ kg/min})(0.0188 - 0.0147) = \mathbf{0.0185 \text{ kg/min}}$$

(b) Energy Balance:

$$\dot{E}_{in} - \dot{E}_{out} = \Delta \dot{E}_{system} \stackrel{\text{no (steady)}}{=} 0$$

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\sum \dot{m}_i h_i = \dot{Q}_{out} + \sum \dot{m}_e h_e \quad \longrightarrow \quad \dot{Q}_{out} = \dot{m}_{a1}h_1 - (\dot{m}_{a2}h_2 + \dot{m}_w h_w) = \dot{m}_a(h_1 - h_2) - \dot{m}_w h_w$$

$$\dot{Q}_{out} = (4.52 \text{ kg/min})(78.3 - 57.5) \text{ kJ/kg} - (0.0185 \text{ kg/min})(83.915 \text{ kJ/kg}) = \mathbf{92.5 \text{ kJ/min}}$$

(c) The inlet and exit enthalpies of the refrigerant are

$$h_3 = h_g + x_3 h_{fg} = 88.82 + 0.2 \times 176.21 = 124.06 \text{ kJ/kg}$$

$$h_4 = h_g @ 700 \text{ kPa} = 265.03 \text{ kJ/kg}$$

Noting that the heat lost by the air is gained by the refrigerant, the mass flow rate of the refrigerant becomes

$$\dot{Q}_R = \dot{m}_R(h_4 - h_3) \quad \longrightarrow \quad \dot{m}_R = \frac{\dot{Q}_R}{h_4 - h_3} = \frac{92.5 \text{ kJ/min}}{(265.03 - 124.06) \text{ kJ/kg}} = \mathbf{0.66 \text{ kg/min}}$$

14-132 Air is cooled and dehumidified in an air-conditioning system with refrigerant-134a as the working fluid. The rate of dehumidification, the rate of heat transfer, and the mass flow rate of the refrigerant are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process. **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis (a) The dew point temperature of the incoming air stream at 30°C is

$$P_{v1} = \phi_1 P_{g1} = \phi_1 P_{\text{sat}@30^\circ\text{C}} = (0.7)(4.247 \text{ kPa}) = 2.973 \text{ kPa}$$

$$T_{\text{dp}} = T_{\text{sat}@P_v} = T_{\text{sat}@2.973 \text{ kPa}} = 23.9^\circ\text{C}$$

Since air is cooled to 20°C, which is below its dew point temperature, some of the moisture in the air will condense.

The amount of moisture in the air decreases due to dehumidification ($\omega_2 < \omega_1$). The inlet and the exit states of the air are completely specified, and the total pressure is 95 kPa. The properties of the air at both states are determined to be

$$P_{a1} = P_1 - P_{v1} = 90 - 2.973 = 87.03 \text{ kPa}$$

$$\nu_1 = \frac{R_a T_1}{P_{a1}} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K})(303 \text{ K})}{87.03 \text{ kPa}} = 0.9992 \text{ m}^3 / \text{kg dry air}$$

$$\omega_1 = \frac{0.622 P_{v1}}{P_1 - P_{v1}} = \frac{0.622(2.973 \text{ kPa})}{(90 - 2.973) \text{ kPa}} = 0.02125 \text{ kg H}_2\text{O/kg dry air}$$

$$h_1 = c_p T_1 + \omega_1 h_{g1} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(30^\circ\text{C}) + (0.02125)(2555.6 \text{ kJ/kg}) = 84.45 \text{ kJ/kg dry air}$$

and

$$P_{v2} = \phi_2 P_{g2} = (1.00)P_{\text{sat}@20^\circ\text{C}} = 2.3392 \text{ kPa}$$

$$\omega_2 = \frac{0.622 P_{v2}}{P_2 - P_{v2}} = \frac{0.622(2.3392 \text{ kPa})}{(95 - 2.3392) \text{ kPa}} = 0.01660 \text{ kg H}_2\text{O/kg dry air}$$

$$h_2 = c_p T_2 + \omega_2 h_{g2} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(20^\circ\text{C}) + (0.01660)(2537.4 \text{ kJ/kg}) = 62.22 \text{ kJ/kg dry air}$$

Also, $h_w \cong h_f @ 20^\circ\text{C} = 83.915 \text{ kJ/kg}$ (Table A-4)

Then, $\dot{m}_{a1} = \frac{\dot{V}_1}{\nu_1} = \frac{4 \text{ m}^3 / \text{min}}{0.9992 \text{ m}^3 / \text{kg dry air}} = 4.003 \text{ kg/min}$

Applying the water mass balance and the energy balance equations to the combined cooling and dehumidification section (excluding the refrigerant),

Water Mass Balance: $\sum \dot{m}_{w,i} = \sum \dot{m}_{w,e} \longrightarrow \dot{m}_{a1}\omega_1 = \dot{m}_{a2}\omega_2 + \dot{m}_w$

$$\dot{m}_w = \dot{m}_a(\omega_1 - \omega_2) = (4.003 \text{ kg/min})(0.02125 - 0.01660) = \mathbf{0.01861 \text{ kg/min}}$$

(b) **Energy Balance:**

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\approx 0 \text{ (steady)}}{=} 0$$

$$\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\sum \dot{m}_i h_i = \dot{Q}_{\text{out}} + \sum \dot{m}_e h_e \longrightarrow \dot{Q}_{\text{out}} = \dot{m}_{a1} h_1 - (\dot{m}_{a2} h_2 + \dot{m}_w h_w) = \dot{m}_a (h_1 - h_2) - \dot{m}_w h_w$$

$$\dot{Q}_{\text{out}} = (4.003 \text{ kg/min})(84.45 - 62.22) \text{ kJ/kg} - (0.01861 \text{ kg/min})(83.915 \text{ kJ/kg}) = \mathbf{87.44 \text{ kJ/min}}$$

(c) The inlet and exit enthalpies of the refrigerant are

$$h_3 = h_g + x_3 h_{fg} = 88.82 + 0.2 \times 176.26 = 124.07 \text{ kJ/kg}$$

$$h_4 = h_g @ 700 \text{ kPa} = 265.08 \text{ kJ/kg}$$

Noting that the heat lost by the air is gained by the refrigerant, the mass flow rate of the refrigerant is determined from

$$\dot{Q}_R = \dot{m}_R (h_4 - h_3)$$

$$\dot{m}_R = \frac{\dot{Q}_R}{h_4 - h_3} = \frac{87.44 \text{ kJ/min}}{(265.08 - 124.07) \text{ kJ/kg}} = \mathbf{0.620 \text{ kg/min}}$$

14-133 Air is heated and dehumidified in an air-conditioning system consisting of a heating section and an evaporative cooler. The temperature and relative humidity of the air when it leaves the heating section, the rate of heat transfer in the heating section, and the rate of water added to the air in the evaporative cooler are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible.

Analysis (a) Assuming the wet-bulb temperature of the air remains constant during the evaporative cooling process, the properties of air at various states are determined from the psychrometric chart (Fig. A-31 or EES) to be

$$\begin{aligned}
 \left. \begin{array}{l} T_1 = 15^\circ\text{C} \\ \phi_1 = 55\% \end{array} \right\} & \begin{array}{l} h_1 = 29.8 \text{ kJ/kg dry air} \\ \omega_1 = 0.00581 \text{ kg/H}_2\text{O/kg dry air} \\ \nu_1 = 0.824 \text{ m}^3/\text{kg} \end{array} \\
 \left. \begin{array}{l} \omega_2 = \omega_1 \\ T_{wb2} = T_{wb3} \end{array} \right\} & \begin{array}{l} T_2 = 32.5^\circ\text{C} \\ \phi_2 = 19.2\% \\ h_2 \cong h_3 = 47.8 \text{ kJ/kg dry air} \end{array} \\
 \left. \begin{array}{l} T_3 = 25^\circ\text{C} \\ \phi_3 = 45\% \end{array} \right\} & \begin{array}{l} h_3 = 47.8 \text{ kJ/kg dry air} \\ \omega_3 = 0.00888 \text{ kg/H}_2\text{O/kg dry air} \\ T_{wb3} = 17.1^\circ\text{C} \end{array}
 \end{aligned}$$

(b) The mass flow rate of dry air is

$$\dot{m}_a = \frac{\dot{V}_1}{\nu_1} = \frac{30 \text{ m}^3/\text{min}}{0.824 \text{ m}^3/\text{kg dry air}} = 36.4 \text{ kg/min}$$

Then the rate of heat transfer to air in the heating section becomes

$$\dot{Q}_{in} = \dot{m}_a (h_2 - h_1) = (36.4 \text{ kg/min})(47.8 - 29.8) \text{ kJ/kg} = \mathbf{655 \text{ kJ/min}}$$

(c) The rate of water added to the air in evaporative cooler is

$$\dot{m}_{w, \text{ added}} = \dot{m}_{w3} - \dot{m}_{w2} = \dot{m}_a (\omega_3 - \omega_2) = (36.4 \text{ kg/min})(0.00888 - 0.00581) = \mathbf{0.112 \text{ kg/min}}$$

14-134 Problem 14-133 is reconsidered. The effect of total pressure in the range 94 to 100 kPa on the results required in the problem is to be studied.

Analysis The problem is solved using EES, and the solution is given below.

```
P=101.325 [kPa]
Tdb[1] =15 [C]

14-135 Air is heated and dehumidified in an air-conditioning system consisting of a heating section and an evaporative cooler. The temperature and relative humidity of the air when it leaves the heating section, the rate of heat transfer in the heating section, and the rate at which water is added to the air in the evaporative cooler are to be determined.

Assumptions 1 This is a steady-flow process and thus the mass flow rate of dry air remains constant during the entire process ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$). **2** Dry air and water vapor are ideal gases. **3** The kinetic and potential energy changes are negligible.

Analysis (a) Assuming the wet-bulb temperature of the air remains constant during the evaporative cooling process, the properties of air at various states are determined to be

$$P_{v1} = \phi_1 P_{g1} = \phi_1 P_{\text{sat}@15^\circ\text{C}} = (0.55)(1.7057 \text{ kPa}) = 0.938 \text{ kPa}$$

$$P_{a1} = P_1 - P_{v1} = 96 - 0.938 = 95.06 \text{ kPa}$$

$$\nu_1 = \frac{R_a T_1}{P_{a1}} = \frac{(0.287 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K})(288 \text{ K})}{95.06 \text{ kPa}}$$

$$= 0.8695 \text{ m}^3 / \text{kg dry air}$$

$$\omega_1 = \frac{0.622 P_{v1}}{P_1 - P_{v1}} = \frac{0.622(0.938 \text{ kPa})}{(96 - 0.8695) \text{ kPa}} = 0.006138 \text{ kg H}_2\text{O/kg dry air}$$

$$h_1 = c_p T_1 + \omega_1 h_{g1} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(15^\circ\text{C}) + (0.006138)(2528.3 \text{ kJ/kg}) = 30.59 \text{ kJ/kg dry air}$$

and

$$P_{v3} = \phi_3 P_{g3} = \phi_3 P_{\text{sat}@25^\circ\text{C}} = (0.45)(3.17 \text{ kPa}) = 1.426 \text{ kPa}$$

$$P_{a3} = P_3 - P_{v3} = 96 - 1.426 = 94.57 \text{ kPa}$$

$$\omega_3 = \frac{0.622 P_{v3}}{P_3 - P_{v3}} = \frac{0.622(1.426 \text{ kPa})}{(96 - 1.426) \text{ kPa}} = 0.009381 \text{ kg H}_2\text{O/kg dry air}$$

$$h_3 = c_p T_3 + \omega_3 h_{g3} = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C})(25^\circ\text{C}) + (0.009381)(2546.5 \text{ kJ/kg}) = 49.01 \text{ kJ/kg dry air}$$

Also,

$$h_2 \cong h_3 = 49.01 \text{ kJ/kg}$$

$$\omega_2 = \omega_1 = 0.006138 \text{ kg H}_2\text{O/kg dry air}$$

Thus,

$$h_2 = c_p T_2 + \omega_2 h_{g2} \cong c_p T_2 + \omega_2 (2500.9 + 1.82 T_2) = (1.005 \text{ kJ/kg} \cdot ^\circ\text{C}) T_2 + (0.006138)(2500.9 + 1.82 T_2)$$

Solving for T_2 ,

$$T_2 = \mathbf{33.1^\circ\text{C}} \longrightarrow P_{g2} = P_{\text{sat}@33.1^\circ\text{C}} = 5.072 \text{ kPa}$$

$$\text{Thus, } \phi_2 = \frac{\omega_2 P_2}{(0.622 + \omega_2) P_{g2}} = \frac{(0.006138)(96)}{(0.622 + 0.006138)(5.072)} = 0.185 \text{ or } \mathbf{18.5\%}$$

(b) The mass flow rate of dry air is

$$\dot{m}_a = \frac{\dot{V}_1}{\nu_1} = \frac{30 \text{ m}^3 / \text{min}}{0.8695 \text{ m}^3 / \text{kg dry air}} = 34.5 \text{ kg/min}$$

Then the rate of heat transfer to air in the heating section becomes

$$\dot{Q}_{\text{in}} = \dot{m}_a (h_2 - h_1) = (34.5 \text{ kg/min})(49.01 - 30.59) \text{ kJ/kg} = \mathbf{636 \text{ kJ/min}}$$

(c) The rate of water addition to the air in evaporative cooler is

$$\dot{m}_{w, \text{added}} = \dot{m}_{w3} - \dot{m}_{w2} = \dot{m}_a (\omega_3 - \omega_2) = (34.5 \text{ kg/min})(0.009381 - 0.006138) = \mathbf{0.112 \text{ kg/min}}$$

14-136 Conditioned air is to be mixed with outside air. The ratio of the dry air mass flow rates of the conditioned- to-outside air, and the temperature of the mixture are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible. 4 The mixing chamber is adiabatic.

Properties The properties of each inlet stream are determined from the psychrometric chart (Fig. A-31) to be

$$h_1 = 34.3 \text{ kJ / kg dry air}$$

$$\omega_1 = 0.0084 \text{ kg H}_2\text{O / kg dry air}$$

and

$$h_2 = 68.5 \text{ kJ / kg dry air}$$

$$\omega_2 = 0.0134 \text{ kg H}_2\text{O / kg dry air}$$

Analysis The ratio of the dry air mass flow rates of the Conditioned air to the outside air can be determined from

$$\frac{\dot{m}_{a1}}{\dot{m}_{a2}} = \frac{\omega_2 - \omega_3}{\omega_3 - \omega_1} = \frac{h_2 - h_3}{h_3 - h_1}$$

But state 3 is not completely specified. However, we know that state 3 is on the straight line connecting states 1 and 2 on the psychrometric chart. At the intersection point of this line and $\phi = 60\%$ line we read

$$(b) \quad T_3 = 23.5^\circ\text{C}$$

$$\omega_3 = 0.0109 \text{ kg H}_2\text{O / kg dry air}$$

$$h_3 = 51.3 \text{ kJ / kg dry air}$$

Therefore, the mixture will leave at 23.5°C . The $\dot{m}_{a1}/\dot{m}_{a2}$ ratio is determined by substituting the specific humidity (or enthalpy) values into the above relation,

$$(a) \quad \frac{\dot{m}_{a1}}{\dot{m}_{a2}} = \frac{0.0134 - 0.0109}{0.0109 - 0.0084} = 1.00$$

Therefore, the mass flow rate of each stream must be the same.

14-137 Problem 14-136 is reconsidered. The desired quantities are to be determined using EES at 1 atm and 80 kPa pressures.

Analysis The problem is solved using EES, and the solution is given below.

"Without loss of generality assume the mass flow rate of the outside air is $m_{\dot{2}} = 1 \text{ kg/s}$."

```
P=101.325 [kPa]
Tdb[1] =13 [C] "State 1 is the conditioned air"

14-138 Waste heat from the cooling water is rejected to air in a natural-draft cooling tower. The mass flow rate of the cooling water, the volume flow rate of air, and the mass flow rate of the required makeup water are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Dry air and water vapor are ideal gases. 3 The kinetic and potential energy changes are negligible. 4 The cooling tower is adiabatic.

Analysis (a) The mass flow rate of dry air through the tower remains constant ($\dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$), but the mass flow rate of liquid water decreases by an amount equal to the amount of water that vaporizes in the tower during the cooling process. The water lost through evaporation is made up later in the cycle using water at 30°C. Applying the mass balance and the energy balance equations yields

Dry Air Mass Balance:

$$\sum \dot{m}_{a,i} = \sum \dot{m}_{a,e} \longrightarrow \dot{m}_{a1} = \dot{m}_{a2} = \dot{m}_a$$

Water Mass Balance:

$$\begin{aligned} \sum \dot{m}_{w,i} &= \sum \dot{m}_{w,e} \\ \dot{m}_3 + \dot{m}_{a1}\omega_1 &= \dot{m}_4 + \dot{m}_{a2}\omega_2 \\ \dot{m}_3 - \dot{m}_4 &= \dot{m}_a(\omega_2 - \omega_1) = \dot{m}_{\text{makeup}} \end{aligned}$$

Energy Balance:

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = \Delta \dot{E}_{\text{system}} \stackrel{\text{no (steady)}}{=} 0 \longrightarrow \dot{E}_{\text{in}} = \dot{E}_{\text{out}}$$

$$\begin{aligned} \sum \dot{m}_i h_i &= \sum \dot{m}_e h_e \quad (\text{since } \dot{Q} = \dot{W} = 0) \\ 0 &= \sum \dot{m}_e h_e - \sum \dot{m}_i h_i \\ 0 &= \dot{m}_{a2} h_2 + \dot{m}_4 h_4 - \dot{m}_{a1} h_1 - \dot{m}_3 h_3 \\ 0 &= \dot{m}_a (h_2 - h_1) + (\dot{m}_3 - \dot{m}_{\text{makeup}}) h_4 - \dot{m}_3 h_3 \end{aligned}$$

Solving for \dot{m}_a ,

$$\dot{m}_a = \frac{\dot{m}_3 (h_3 - h_4)}{(h_2 - h_1) - (\omega_2 - \omega_1) h_4}$$

From the psychrometric chart (Fig. A-31 or EES),

$$\begin{aligned} h_1 &= 44.67 \text{ kJ/kg dry air} \\ \omega_1 &= 0.008462 \text{ kg H}_2\text{O/kg dry air} \\ \nu_1 &= 0.8504 \text{ m}^3/\text{kg dry air} \end{aligned}$$

and

$$\begin{aligned} h_2 &= 110.69 \text{ kJ/kg dry air} \\ \omega_2 &= 0.03065 \text{ kg H}_2\text{O/kg dry air} \end{aligned}$$

From Table A-4,

$$\begin{aligned} h_3 &\cong h_f @ 42^\circ\text{C} = 175.90 \text{ kJ/kg H}_2\text{O} \\ h_4 &\cong h_f @ 30^\circ\text{C} = 125.74 \text{ kJ/kg H}_2\text{O} \end{aligned}$$

Substituting

$$\dot{m}_a = \frac{\dot{m}_3 (175.90 - 125.74) \text{ kJ/kg}}{(110.69 - 44.67) \text{ kJ/kg} - (0.03065 - 0.008462)(125.74) \text{ kJ/kg}} = 0.7933 \dot{m}_3$$

The mass flow rate of the cooling water is determined by applying the steady flow energy balance equation on the cooling water,

$$\begin{aligned}\dot{Q}_{\text{waste}} &= \dot{m}_3 h_3 - (\dot{m}_3 - \dot{m}_{\text{makeup}}) h_4 = \dot{m}_3 h_3 - [\dot{m}_3 - \dot{m}_a (\omega_2 - \omega_1)] h_4 \\ &= \dot{m}_3 h_3 - \dot{m}_3 [1 - 0.7933(0.03065 - 0.008462)] h_4 \\ &= \dot{m}_3 (h_3 - 0.9824 h_4)\end{aligned}$$

$$70,000 \text{ kJ/s} = \dot{m}_3 (175.90 - 0.9824 \times 125.74) \text{ kJ/kg} \longrightarrow \dot{m}_3 = \mathbf{1337 \text{ kg/s}}$$

and

$$\dot{m}_a = 0.7933 \dot{m}_3 = (0.7933)(1337 \text{ kg/s}) = 1061 \text{ kg/s}$$

(b) Then the volume flow rate of air into the cooling tower becomes

$$\dot{V}_1 = \dot{m}_a \nu_1 = (1061 \text{ kg/s})(0.8504 \text{ m}^3 / \text{kg}) = \mathbf{902 \text{ m}^3/\text{s}}$$

(c) The mass flow rate of the required makeup water is determined from

$$\dot{m}_{\text{makeup}} = \dot{m}_a (\omega_2 - \omega_1) = (1061 \text{ kg/s})(0.03065 - 0.008462) = \mathbf{23.5 \text{ kg/s}}$$

14-139 Problem 14-138 is reconsidered. The effect of air inlet wet-bulb temperature on the required air volume flow rate and the makeup water flow rate is to be investigated.

Analysis The problem is solved using EES, and the solution is given below.

14-145 On the psychrometric chart, a cooling and dehumidification process appears as a line that is

- (a) horizontal to the left,
 (b) vertical downward,
 (c) diagonal upwards to the right (NE direction)
 (d) diagonal upwards to the left (NW direction)
 (e) diagonal downwards to the left (SW direction)

Answer (e) diagonal downwards to the left (SW direction)

14-146 On the psychrometric chart, a heating and humidification process appears as a line that is

- (a) horizontal to the right,
 (b) vertical upward,
 (c) diagonal upwards to the right (NE direction)
 (d) diagonal upwards to the left (NW direction)
 (e) diagonal downwards to the right (SE direction)

Answer (c) diagonal upwards to the right (NE direction)

14-147 An air stream at a specified temperature and relative humidity undergoes evaporative cooling by spraying water into it at about the same temperature. The lowest temperature the air stream can be cooled to is

- (a) the dry bulb temperature at the given state
- (b) the wet bulb temperature at the given state
- (c) the dew point temperature at the given state
- (d) the saturation temperature corresponding to the humidity ratio at the given state
- (e) the triple point temperature of water

Answer (a) the dry bulb temperature at the given state

14-148 Air is cooled and dehumidified as it flows over the coils of a refrigeration system at 85 kPa from 35°C and a humidity ratio of 0.023 kg/kg dry air to 15°C and a humidity ratio of 0.015 kg/kg dry air. If the mass flow rate of dry air is 0.4 kg/s, the rate of heat removal from the air is

- (a) 4 kJ/s
- (b) 8 kJ/s
- (c) 12 kJ/s
- (d) 16 kJ/s
- (e) 20 kJ/s

Answer (d) 16 kJ/s

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
P=85 "kPa"
T1=35 "C"

Fuels and Combustion

15-1C Nitrogen, in general, does not react with other chemical species during a combustion process but its presence affects the outcome of the process because nitrogen absorbs a large proportion of the heat released during the chemical process.

15-2C The number of atoms are preserved during a chemical reaction, but the total mole numbers are not.

15-3C Air-fuel ratio is the ratio of the mass of air to the mass of fuel during a combustion process. Fuel-air ratio is the inverse of the air-fuel ratio.

15-4C No. Because the molar mass of the fuel and the molar mass of the air, in general, are different.

15-5C The dew-point temperature of the product gases is the temperature at which the water vapor in the product gases starts to condense as the gases are cooled at constant pressure. It is the saturation temperature corresponding to the vapor pressure of the product gases.

15-6 Sulfur is burned with oxygen to form sulfur dioxide. The minimum mass of oxygen required and the mass of sulfur dioxide in the products are to be determined when 1 kg of sulfur is burned.

Properties The molar masses of sulfur and oxygen are 32.06 kg/kmol and 32.00 kg/kmol, respectively (Table A-1).

Analysis The chemical reaction is given by

Hence, 1 kmol of oxygen is required to burn 1 kmol of sulfur which produces 1 kmol of sulfur dioxide whose molecular weight is

$$M_{\text{SO}_2} = M_{\text{S}} + M_{\text{O}_2} = 32.06 + 32.00 = 64.06 \text{ kg/kmol}$$

Then,

$$\frac{m_{\text{O}_2}}{m_{\text{S}}} = \frac{N_{\text{O}_2} M_{\text{O}_2}}{N_{\text{S}} M_{\text{S}}} = \frac{(1 \text{ kmol})(32 \text{ kg/kmol})}{(1 \text{ kmol})(32.06 \text{ kg/kmol})} = \mathbf{0.998 \text{ kg O}_2/\text{kg S}}$$

and

$$\frac{m_{\text{SO}_2}}{m_{\text{S}}} = \frac{N_{\text{SO}_2} M_{\text{SO}_2}}{N_{\text{S}} M_{\text{S}}} = \frac{(1 \text{ kmol})(64.06 \text{ kg/kmol})}{(1 \text{ kmol})(32.06 \text{ kg/kmol})} = \mathbf{1.998 \text{ kg SO}_2/\text{kg S}}$$

15-7E Methane is burned with diatomic oxygen. The mass of water vapor in the products is to be determined when 1 lbm of methane is burned.

Properties The molar masses of CH₄, O₂, CO₂, and H₂O are 16, 32, 44, and 18 lbm/lbmol, respectively (Table A-1E).

Analysis The chemical reaction is given by

Hence, for each lbmol of methane burned, 2 lbmol of water vapor are formed. Then,

$$\frac{m_{\text{H}_2\text{O}}}{m_{\text{CH}_4}} = \frac{N_{\text{H}_2\text{O}}M_{\text{H}_2\text{O}}}{N_{\text{CH}_4}M_{\text{CH}_4}} = \frac{(2 \text{ lbmol})(18 \text{ lbm/lbmol})}{(1 \text{ lbmol})(16 \text{ lbm/lbmol})} = \mathbf{2.25 \text{ lbm H}_2\text{O/lbm CH}_4}$$

Theoretical and Actual Combustion Processes

15-8C It represent the amount of air that contains the exact amount of oxygen needed for complete combustion.

15-9C Case (b).

15-10C No. The theoretical combustion is also complete, but the products of theoretical combustion does not contain any uncombined oxygen.

15-11C The causes of incomplete combustion are insufficient time, insufficient oxygen, insufficient mixing, and dissociation.

15-12C CO. Because oxygen is more strongly attracted to hydrogen than it is to carbon, and hydrogen is usually burned to completion even when there is a deficiency of oxygen.

15-13 Methane is burned with the stoichiometric amount of air during a combustion process. The AF and FA ratios are to be determined.

Assumptions 1 Combustion is complete. **2** The combustion products contain CO_2 , H_2O , and N_2 only.

Properties The molar masses of C, H_2 , and air are 12 kg/kmol, 2 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis This is a theoretical combustion process since methane is burned completely with stoichiometric amount of air. The stoichiometric combustion equation of CH_4 is

$$\text{O}_2 \text{ balance: } a_{\text{th}} = 1 + 1 \longrightarrow a_{\text{th}} = 2$$

Substituting,

The air-fuel ratio is determined by taking the ratio of the mass of the air to the mass of the fuel,

$$\text{AF} = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{(2 \times 4.76 \text{ kmol})(29 \text{ kg/kmol})}{(1 \text{ kmol})(12 \text{ kg/kmol}) + (2 \text{ kmol})(2 \text{ kg/kmol})} = \mathbf{17.3 \text{ kg air/kg fuel}}$$

The fuel-air ratio is the inverse of the air-fuel ratio,

$$\text{FA} = \frac{1}{\text{AF}} = \frac{1}{17.3 \text{ kg air/kg fuel}} = \mathbf{0.0578 \text{ kg fuel/kg air}}$$

15-14 Propane is burned with theoretical amount of air. The mass fraction of carbon dioxide and the mole and mass fractions of the water vapor in the products are to be determined.

Properties The molar masses of C_3H_8 , O_2 , N_2 , CO_2 , and H_2O are 44, 32, 28, 44, and 18 kg/kmol, respectively (Table A-1).

Analysis (a) The reaction in terms of undetermined coefficients is

Balancing the carbon in this reaction gives

$$y = 3$$

and the hydrogen balance gives

$$2z = 8 \longrightarrow z = 4$$

The oxygen balance produces

$$2x = 2y + z \longrightarrow x = y + z/2 = 3 + 4/2 = 5$$

A balance of the nitrogen in this reaction gives

$$2 \times 3.76x = 2p \longrightarrow p = 3.76x = 3.76 \times 5 = 18.8$$

In balanced form, the reaction is

The mass fraction of carbon dioxide is determined from

$$\begin{aligned} mf_{CO_2} &= \frac{m_{CO_2}}{m_{products}} = \frac{N_{CO_2}M_{CO_2}}{N_{CO_2}M_{CO_2} + N_{H_2O}M_{H_2O} + N_{N_2}M_{N_2}} \\ &= \frac{(3 \text{ kmol})(44 \text{ kg/kmol})}{(3 \text{ kmol})(44 \text{ kg/kmol}) + (4 \text{ kmol})(18 \text{ kg/kmol}) + (18.8 \text{ kmol})(28 \text{ kg/kmol})} \\ &= \frac{132 \text{ kg}}{730.4 \text{ kg}} = \mathbf{0.181} \end{aligned}$$

(b) The mole and mass fractions of water vapor are

$$y_{H_2O} = \frac{N_{H_2O}}{N_{products}} = \frac{N_{H_2O}}{N_{CO_2} + N_{H_2O} + N_{N_2}} = \frac{4 \text{ kmol}}{3 \text{ kmol} + 4 \text{ kmol} + 18.8 \text{ kmol}} = \frac{4 \text{ kmol}}{25.8 \text{ kmol}} = \mathbf{0.155}$$

$$\begin{aligned} mf_{H_2O} &= \frac{m_{H_2O}}{m_{products}} = \frac{N_{H_2O}M_{H_2O}}{N_{CO_2}M_{CO_2} + N_{H_2O}M_{H_2O} + N_{N_2}M_{N_2}} \\ &= \frac{(4 \text{ kmol})(18 \text{ kg/kmol})}{(3 \text{ kmol})(44 \text{ kg/kmol}) + (4 \text{ kmol})(18 \text{ kg/kmol}) + (18.8 \text{ kmol})(28 \text{ kg/kmol})} \\ &= \frac{72 \text{ kg}}{730.4 \text{ kg}} \\ &= \mathbf{0.0986} \end{aligned}$$

15-15 n-Butane is burned with stoichiometric amount of oxygen. The mole fractions of CO₂ water in the products and the mole number of CO₂ in the products per mole of fuel burned are to be determined.

Assumptions **1** Combustion is complete. **2** The combustion products contain CO₂ and H₂O. **3** Combustion gases are ideal gases.

Properties The molar masses of C, H₂, and O₂ are 12 kg/kmol, 2 kg/kmol, and 32 kg/kmol, respectively (Table A-1).

Analysis The combustion equation in this case is

The total mole of the products are $4+5 = 9$ kmol. Then the mole fractions are

$$y_{\text{CO}_2} = \frac{N_{\text{CO}_2}}{N_{\text{total}}} = \frac{4 \text{ kmol}}{9 \text{ kmol}} = \mathbf{0.4444}$$

$$y_{\text{H}_2\text{O}} = \frac{N_{\text{H}_2\text{O}}}{N_{\text{total}}} = \frac{5 \text{ kmol}}{9 \text{ kmol}} = \mathbf{0.5556}$$

Also,

$$N_{\text{CO}_2} = \mathbf{4 \text{ kmol CO}_2/\text{kmol C}_4\text{H}_{10}}$$

15-16 Acetylene is burned with 25 percent excess oxygen. The mass fractions of each of the products and the mass of oxygen used per unit mass of fuel burned are to be determined.

Assumptions 1 Combustion is complete. **2** The combustion products contain CO_2 , H_2O , and O_2 . **3** Combustion gases are ideal gases.

Properties The molar masses of C, H_2 , and O_2 are 12 kg/kmol, 2 kg/kmol, and 32 kg/kmol, respectively (Table A-1).

Analysis The stoichiometric combustion equation is

The combustion equation with 25% excess oxygen is

or

The mass of each product and the total mass are

$$m_{\text{CO}_2} = N_{\text{CO}_2} M_{\text{CO}_2} = (2 \text{ kmol})(44 \text{ kg/kmol}) = 88 \text{ kg}$$

$$m_{\text{H}_2\text{O}} = N_{\text{H}_2\text{O}} M_{\text{H}_2\text{O}} = (1 \text{ kmol})(18 \text{ kg/kmol}) = 18 \text{ kg}$$

$$m_{\text{O}_2} = N_{\text{O}_2} M_{\text{O}_2} = (0.625 \text{ kmol})(32 \text{ kg/kmol}) = 20 \text{ kg}$$

$$m_{\text{total}} = m_{\text{CO}_2} + m_{\text{H}_2\text{O}} + m_{\text{O}_2} = 88 + 18 + 20 = 126 \text{ kg}$$

Then the mass fractions are

$$\text{mf}_{\text{CO}_2} = \frac{m_{\text{CO}_2}}{m_{\text{total}}} = \frac{88 \text{ kg}}{126 \text{ kg}} = \mathbf{0.6984}$$

$$\text{mf}_{\text{H}_2\text{O}} = \frac{m_{\text{H}_2\text{O}}}{m_{\text{total}}} = \frac{18 \text{ kg}}{126 \text{ kg}} = \mathbf{0.1429}$$

$$\text{mf}_{\text{O}_2} = \frac{m_{\text{O}_2}}{m_{\text{total}}} = \frac{20 \text{ kg}}{126 \text{ kg}} = \mathbf{0.1587}$$

The mass of oxygen per unit mass of fuel burned is determined from

$$\frac{m_{\text{O}_2}}{m_{\text{C}_2\text{H}_2}} = \frac{(3.125 \times 32) \text{ kg}}{(1 \times 26) \text{ kg}} = \mathbf{3.846 \text{ kg O}_2/\text{kg C}_2\text{H}_2}$$

15-17 Propyl alcohol C_3H_7OH is burned with 50 percent excess air. The balanced reaction equation for complete combustion is to be written and the air-to-fuel ratio is to be determined.

Assumptions 1 Combustion is complete. 2 The combustion products contain CO_2 , H_2O , O_2 , and N_2 only.

Properties The molar masses of C, H_2 , O_2 and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis The combustion equation in this case can be written as

where a_{th} is the stoichiometric coefficient for air. We have automatically accounted for the 50% excess air by using the factor $1.5a_{th}$ instead of a_{th} for air. The coefficient a_{th} and other coefficients are to be determined from the mass balances

Carbon balance: $B = 3$

Hydrogen balance: $2D = 8 \longrightarrow D = 4$

Oxygen balance: $1 + 2 \times 1.5a_{th} = 2B + D + 2E$

$$0.5a_{th} = E$$

Nitrogen balance: $1.5a_{th} \times 3.76 = F$

Solving the above equations, we find the coefficients ($E = 2.25$, $F = 25.38$, and $a_{th} = 4.5$) and write the balanced reaction equation as

The air-fuel ratio is determined by taking the ratio of the mass of the air to the mass of the fuel,

$$AF = \frac{m_{air}}{m_{fuel}} = \frac{(6.75 \times 4.75 \text{ kmol})(29 \text{ kg/kmol})}{(3 \times 12 + 8 \times 1 + 1 \times 16) \text{ kg}} = \mathbf{15.51 \text{ kg air/kg fuel}}$$

15-18 n-Octane is burned with 50 percent excess air. The mole fractions of each of the products, the mass of water in the products per unit mass of the fuel, and the mass fraction of each reactant are to be determined.

Assumptions 1 Combustion is complete. **2** The combustion products contain CO_2 , H_2O , O_2 , and N_2 only.

Properties The molar masses of C, H_2 , O_2 , and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis The combustion equation in this case can be written as

where a_{th} is the stoichiometric coefficient for air. We have automatically accounted for the 50% excess air by using the factor $1.5a_{\text{th}}$ instead of a_{th} for air. The stoichiometric amount of oxygen ($a_{\text{th}}\text{O}_2$) will be used to oxidize the fuel, and the remaining excess amount ($0.5a_{\text{th}}\text{O}_2$) will appear in the products as free oxygen. The coefficient a_{th} is determined from the O_2 balance,

$$\text{O}_2 \text{ balance: } 1.5a_{\text{th}} = 8 + 4.5 + 0.5a_{\text{th}} \longrightarrow a_{\text{th}} = 12.5$$

$$\text{Substituting, } \text{C}_8\text{H}_{18} + 18.75[\text{O}_2 + 3.76\text{N}_2] \longrightarrow 8\text{CO}_2 + 9\text{H}_2\text{O} + 6.25\text{O}_2 + 70.5\text{N}_2$$

The mass of each product and the total mass are

$$m_{\text{CO}_2} = N_{\text{CO}_2}M_{\text{CO}_2} = (8 \text{ kmol})(44 \text{ kg/kmol}) = 352 \text{ kg}$$

$$m_{\text{H}_2\text{O}} = N_{\text{H}_2\text{O}}M_{\text{H}_2\text{O}} = (9 \text{ kmol})(18 \text{ kg/kmol}) = 162 \text{ kg}$$

$$m_{\text{O}_2} = N_{\text{O}_2}M_{\text{O}_2} = (6.25 \text{ kmol})(32 \text{ kg/kmol}) = 200 \text{ kg}$$

$$m_{\text{N}_2} = N_{\text{N}_2}M_{\text{N}_2} = (70.5 \text{ kmol})(28 \text{ kg/kmol}) = 1974 \text{ kg}$$

$$m_{\text{total}} = m_{\text{CO}_2} + m_{\text{H}_2\text{O}} + m_{\text{O}_2} + m_{\text{N}_2} = 352 + 162 + 200 + 1974 = 2688 \text{ kg}$$

Then the mass fractions are

$$\text{mf}_{\text{CO}_2} = \frac{m_{\text{CO}_2}}{m_{\text{total}}} = \frac{352 \text{ kg}}{2688 \text{ kg}} = \mathbf{0.1310}$$

$$\text{mf}_{\text{H}_2\text{O}} = \frac{m_{\text{H}_2\text{O}}}{m_{\text{total}}} = \frac{162 \text{ kg}}{2688 \text{ kg}} = \mathbf{0.0603}$$

$$\text{mf}_{\text{O}_2} = \frac{m_{\text{O}_2}}{m_{\text{total}}} = \frac{200 \text{ kg}}{2688 \text{ kg}} = \mathbf{0.0744}$$

$$\text{mf}_{\text{N}_2} = \frac{m_{\text{N}_2}}{m_{\text{total}}} = \frac{1974 \text{ kg}}{2688 \text{ kg}} = \mathbf{0.7344}$$

The mass of water per unit mass of fuel burned is

$$\frac{m_{\text{H}_2\text{O}}}{m_{\text{C}_8\text{H}_{18}}} = \frac{(9 \times 18) \text{ kg}}{(1 \times 114) \text{ kg}} = \mathbf{1.421 \text{ kg H}_2\text{O/kg C}_8\text{H}_{18}}$$

The mass of each reactant and the total mass are

$$m_{\text{C}_8\text{H}_{18}} = N_{\text{C}_8\text{H}_{18}}M_{\text{C}_8\text{H}_{18}} = (1 \text{ kmol})(114 \text{ kg/kmol}) = 114 \text{ kg}$$

$$m_{\text{air}} = N_{\text{air}}M_{\text{air}} = (17.75 \times 4.76 \text{ kmol})(29 \text{ kg/kmol}) = 2588 \text{ kg}$$

$$m_{\text{total}} = m_{\text{C}_8\text{H}_{18}} + m_{\text{air}} = 114 + 2588 = 2702 \text{ kg}$$

Then the mass fractions of reactants are

$$\text{mf}_{\text{C}_8\text{H}_{18}} = \frac{m_{\text{C}_8\text{H}_{18}}}{m_{\text{total}}} = \frac{114 \text{ kg}}{2702 \text{ kg}} = \mathbf{0.0422}$$

$$\text{mf}_{\text{air}} = \frac{m_{\text{air}}}{m_{\text{total}}} = \frac{2588 \text{ kg}}{2702 \text{ kg}} = \mathbf{0.9578}$$

15-19 Ethane is burned with air steadily. The mass flow rates of ethane and air are given. The percentage of excess air used is to be determined.

Assumptions 1 Combustion is complete. **2** The combustion products contain CO_2 , H_2O , and N_2 only.

Properties The molar masses of C, H_2 , and air are 12 kg/kmol, 2 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis The theoretical combustion equation in this case can be written as

where a_{th} is the stoichiometric coefficient for air. It is determined from

$$\text{O}_2 \text{ balance: } a_{\text{th}} = 2 + 1.5 \longrightarrow a_{\text{th}} = 3.5$$

The air-fuel ratio for the theoretical reaction is determined by taking the ratio of the mass of the air to the mass of the fuel for,

$$\text{AF}_{\text{th}} = \frac{m_{\text{air,th}}}{m_{\text{fuel}}} = \frac{(3.5 \times 4.76 \text{ kmol})(29 \text{ kg/kmol})}{(2 \text{ kmol})(12 \text{ kg/kmol}) + (3 \text{ kmol})(2 \text{ kg/kmol})} = 16.1 \text{ kg air/kg fuel}$$

The actual air-fuel ratio used is

$$\text{AF}_{\text{act}} = \frac{\dot{m}_{\text{air}}}{\dot{m}_{\text{fuel}}} = \frac{176 \text{ kg/h}}{8 \text{ kg/h}} = 22 \text{ kgair/kgfuel}$$

Then the percent theoretical air used can be determined from

$$\text{Percent theoretical air} = \frac{\text{AF}_{\text{act}}}{\text{AF}_{\text{th}}} = \frac{22 \text{ kg air/kg fuel}}{16.1 \text{ kg air/kg fuel}} = 137\%$$

Thus the excess air used during this process is **37%**.

15-20 Ethane is burned with an unknown amount of air during a combustion process. The AF ratio and the percentage of theoretical air used are to be determined.

Assumptions 1 Combustion is complete. **2** The combustion products contain CO_2 , H_2O , O_2 , and N_2 only.

Properties The molar masses of C, H_2 , and air are 12 kg/kmol, 2 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis (a) The combustion equation in this case can be written as

O_2 balance: $a = 2 + 1.5 + 3 \longrightarrow a = 6.5$

Substituting,

The air-fuel ratio is determined by taking the ratio of the mass of the air to the mass of the fuel,

$$\text{AF} = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{(6.5 \times 4.76 \text{ kmol})(29 \text{ kg/kmol})}{(2 \text{ kmol})(12 \text{ kg/kmol}) + (3 \text{ kmol})(2 \text{ kg/kmol})} = \mathbf{29.9 \text{ kg air/kg fuel}}$$

(b) To find the percent theoretical air used, we need to know the theoretical amount of air, which is determined from the theoretical combustion equation of C_2H_6 ,

O_2 balance: $a_{\text{th}} = 2 + 1.5 \longrightarrow a_{\text{th}} = 3.5$

Then,

$$\text{Percent theoretical air} = \frac{m_{\text{air,act}}}{m_{\text{air,th}}} = \frac{N_{\text{air,act}}}{N_{\text{air,th}}} = \frac{a}{a_{\text{th}}} = \frac{6.5}{3.5} = \mathbf{186\%}$$

15-21E Ethylene is burned with 175 percent theoretical air during a combustion process. The AF ratio and the dew-point temperature of the products are to be determined.

Assumptions 1 Combustion is complete. **2** The combustion products contain CO_2 , H_2O , O_2 , and N_2 only. **3** Combustion gases are ideal gases.

Properties The molar masses of C, H_2 , and air are 12 lbm/lbmol, 2 lbm/lbmol, and 29 lbm/lbmol, respectively (Table A-1E).

Analysis (a) The combustion equation in this case can be written as

where a_{th} is the stoichiometric coefficient for air. It is determined from

$$\text{O}_2 \text{ balance: } 1.75a_{\text{th}} = 2 + 1 + 0.75a_{\text{th}} \longrightarrow a_{\text{th}} = 3$$

Substituting,

The air-fuel ratio is determined by taking the ratio of the mass of the air to the mass of the fuel,

$$\text{AF} = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{(5.25 \times 4.76 \text{ lbmol})(29 \text{ lbm/lbmol})}{(2 \text{ lbmol})(12 \text{ lbm/lbmol}) + (2 \text{ lbmol})(2 \text{ lbm/lbmol})} = \mathbf{25.9 \text{ lbm air/lbm fuel}}$$

(b) The dew-point temperature of a gas-vapor mixture is the saturation temperature of the water vapor in the product gases corresponding to its partial pressure. That is,

$$P_v = \left(\frac{N_v}{N_{\text{prod}}} \right) P_{\text{prod}} = \left(\frac{2 \text{ lbmol}}{25.99 \text{ lbmol}} \right) (14.5 \text{ psia}) = 1.116 \text{ psia}$$

Thus,

$$T_{\text{dp}} = T_{\text{sat}@1.116 \text{ psia}} = \mathbf{105.4^\circ\text{F}}$$

15-22 Butane is burned with air. The masses of butane and air are given. The percentage of theoretical air used and the dew-point temperature of the products are to be determined.

Assumptions 1 Combustion is complete. **2** The combustion products contain CO_2 , H_2O , and N_2 only. **3** Combustion gases are ideal gases.

Properties The molar masses of C, H_2 , and air are 12 kg/kmol, 2 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis (a) The theoretical combustion equation in this case can be written as

where a_{th} is the stoichiometric coefficient for air. It is determined from

$$\text{O}_2 \text{ balance: } a_{\text{th}} = 4 + 2.5 \longrightarrow a_{\text{th}} = 6.5$$

The air-fuel ratio for the theoretical reaction is determined by taking the ratio of the mass of the air to the mass of the fuel for,

$$\text{AF}_{\text{th}} = \frac{m_{\text{air,th}}}{m_{\text{fuel}}} = \frac{(6.5 \times 4.76 \text{ kmol})(29 \text{ kg/kmol})}{(4 \text{ kmol})(12 \text{ kg/kmol}) + (5 \text{ kmol})(2 \text{ kg/kmol})} = 15.5 \text{ kg air/kg fuel}$$

The actual air-fuel ratio used is

$$\text{AF}_{\text{act}} = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{25 \text{ kg}}{1 \text{ kg}} = 25 \text{ kg air / kg fuel}$$

Then the percent theoretical air used can be determined from

$$\text{Percent theoretical air} = \frac{\text{AF}_{\text{act}}}{\text{AF}_{\text{th}}} = \frac{25 \text{ kg air/kg fuel}}{15.5 \text{ kg air/kg fuel}} = \mathbf{161\%}$$

(b) The combustion is complete, and thus products will contain only CO_2 , H_2O , O_2 and N_2 . The air-fuel ratio for this combustion process on a mole basis is

$$\overline{\text{AF}} = \frac{N_{\text{air}}}{N_{\text{fuel}}} = \frac{m_{\text{air}} / M_{\text{air}}}{m_{\text{fuel}} / M_{\text{fuel}}} = \frac{(25 \text{ kg}) / (29 \text{ kg/kmol})}{(1 \text{ kg}) / (58 \text{ kg/kmol})} = 50 \text{ kmol air/kmol fuel}$$

Thus the combustion equation in this case can be written as

The dew-point temperature of a gas-vapor mixture is the saturation temperature of the water vapor in the product gases corresponding to its partial pressure. That is,

$$P_v = \left(\frac{N_v}{N_{\text{prod}}} \right) P_{\text{prod}} = \left(\frac{5 \text{ kmol}}{52.5 \text{ kmol}} \right) (90 \text{ kPa}) = 8.571 \text{ kPa}$$

Thus,

$$T_{\text{dp}} = T_{\text{sat}@8.571 \text{ kPa}} = \mathbf{42.8^\circ\text{C}}$$

15-23E Butane is burned with air. The masses of butane and air are given. The percentage of theoretical air used and the dew-point temperature of the products are to be determined.

Assumptions 1 Combustion is complete. **2** The combustion products contain CO_2 , H_2O , and N_2 only. **3** Combustion gases are ideal gases.

Properties The molar masses of C, H_2 , and air are 12 lbm/lbmol, 2 lbm/lbmol, and 29 lbm/lbmol, respectively (Table A-1).

Analysis (a) The theoretical combustion equation in this case can be written as

where a_{th} is the stoichiometric coefficient for air. It is determined from

$$\text{O}_2 \text{ balance: } a_{\text{th}} = 4 + 2.5 \longrightarrow a_{\text{th}} = 6.5$$

The air-fuel ratio for the theoretical reaction is determined by taking the ratio of the mass of the air to the mass of the fuel for,

$$\text{AF}_{\text{th}} = \frac{m_{\text{air,th}}}{m_{\text{fuel}}} = \frac{(6.5 \times 4.76 \text{ lbmol})(29 \text{ lbm/lbmol})}{(4 \text{ lbmol})(12 \text{ lbm/lbmol}) + (5 \text{ lbmol})(2 \text{ lbm/lbmol})} = 15.5 \text{ lbm air/lbm fuel}$$

The actual air-fuel ratio used is

$$\text{AF}_{\text{act}} = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{25 \text{ lbm}}{1 \text{ lbm}} = 25 \text{ lbm air/lbm fuel}$$

Then the percent theoretical air used can be determined from

$$\text{Percent theoretical air} = \frac{\text{AF}_{\text{act}}}{\text{AF}_{\text{th}}} = \frac{25 \text{ lbm air/lbm fuel}}{15.5 \text{ lbm air/lbm fuel}} = \mathbf{161\%}$$

(b) The combustion is complete, and thus products will contain only CO_2 , H_2O , O_2 and N_2 . The air-fuel ratio for this combustion process on a mole basis is

$$\overline{\text{AF}} = \frac{N_{\text{air}}}{N_{\text{fuel}}} = \frac{m_{\text{air}} / M_{\text{air}}}{m_{\text{fuel}} / M_{\text{fuel}}} = \frac{(25 \text{ lbm}) / (29 \text{ lbm/lbmol})}{(1 \text{ lbm}) / (58 \text{ lbm/lbmol})} = 50 \text{ lbmol air/lbmol fuel}$$

Thus the combustion equation in this case can be written as

The dew-point temperature of a gas-vapor mixture is the saturation temperature of the water vapor in the product gases corresponding to its partial pressure. That is,

$$P_v = \left(\frac{N_v}{N_{\text{prod}}} \right) P_{\text{prod}} = \left(\frac{5 \text{ lbmol}}{52.5 \text{ lbmol}} \right) (14.7 \text{ psia}) = 1.4 \text{ psia}$$

Thus,

$$T_{\text{dp}} = T_{\text{sat}@1.4 \text{ psia}} = \mathbf{113.2^\circ\text{F}}$$

15-24 Butane C_4H_{10} is burned with 200 percent theoretical air. The kmol of water that needs to be sprayed into the combustion chamber per kmol of fuel is to be determined.

Assumptions 1 Combustion is complete. **2** The combustion products contain CO_2 , H_2O , O_2 , and N_2 only.

Properties The molar masses of C, H_2 , O_2 and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis The reaction equation for 200% theoretical air without the additional water is

where a_{th} is the stoichiometric coefficient for air. We have automatically accounted for the 100% excess air by using the factor $2a_{th}$ instead of a_{th} for air. The coefficient a_{th} and other coefficients are to be determined from the mass balances

Carbon balance: $B = 4$

Hydrogen balance: $2D = 10 \longrightarrow D = 5$

Oxygen balance: $2 \times 2a_{th} = 2B + D + 2E$

$$a_{th} = E$$

Nitrogen balance: $2a_{th} \times 3.76 = F$

Solving the above equations, we find the coefficients ($E = 6.5$, $F = 48.88$, and $a_{th} = 6.5$) and write the balanced reaction equation as

With the additional water sprayed into the combustion chamber, the balanced reaction equation is

The partial pressure of water in the saturated product mixture at the dew point is

$$P_{v,prod} = P_{sat @ 50^\circ C} = 12.35 \text{ kPa}$$

The vapor mole fraction is

$$y_v = \frac{P_{v,prod}}{P_{prod}} = \frac{12.35 \text{ kPa}}{100 \text{ kPa}} = 0.1235$$

The amount of water that needs to be sprayed into the combustion chamber can be determined from

$$y_v = \frac{N_{water}}{N_{total,product}} \longrightarrow 0.1235 = \frac{5 + N_v}{4 + 5 + N_v + 6.5 + 48.88} \longrightarrow N_v = \mathbf{3.37 \text{ kmol}}$$

15-25 A fuel mixture of 60% by mass methane, CH_4 , and 40% by mass ethanol, $\text{C}_2\text{H}_6\text{O}$, is burned completely with theoretical air. The required flow rate of air is to be determined.

Assumptions 1 Combustion is complete. **2** The combustion products contain CO_2 , H_2O , and N_2 only.

Properties The molar masses of C, H_2 , O_2 and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis For 100 kg of fuel mixture, the mole numbers are

$$N_{\text{CH}_4} = \frac{mf_{\text{CH}_4}}{M_{\text{CH}_4}} = \frac{60 \text{ kg}}{16 \text{ kg/kmol}} = 3.75 \text{ kmol}$$

$$N_{\text{C}_2\text{H}_6\text{O}} = \frac{mf_{\text{C}_2\text{H}_6\text{O}}}{M_{\text{C}_2\text{H}_6\text{O}}} = \frac{40 \text{ kg}}{46 \text{ kg/kmol}} = 0.8696 \text{ kmol}$$

The mole fraction of methane and ethanol in the fuel mixture are

$$x = \frac{N_{\text{CH}_4}}{N_{\text{CH}_4} + N_{\text{C}_2\text{H}_6\text{O}}} = \frac{3.75 \text{ kmol}}{(3.75 + 0.8696) \text{ kmol}} = 0.8118$$

$$y = \frac{N_{\text{C}_2\text{H}_6\text{O}}}{N_{\text{CH}_4} + N_{\text{C}_2\text{H}_6\text{O}}} = \frac{0.8696 \text{ kmol}}{(3.75 + 0.8696) \text{ kmol}} = 0.1882$$

The combustion equation in this case can be written as

where a_{th} is the stoichiometric coefficient for air. The coefficient a_{th} and other coefficients are to be determined from the mass balances

$$\begin{aligned} \text{Carbon balance:} \quad & x + 2y = B \\ \text{Hydrogen balance:} \quad & 4x + 6y = 2D \\ \text{Oxygen balance:} \quad & 2a_{\text{th}} + y = 2B + D \\ \text{Nitrogen balance:} \quad & 3.76a_{\text{th}} = F \end{aligned}$$

Substituting x and y values into the equations and solving, we find the coefficients as

$$\begin{aligned} x &= 0.8118 & B &= 1.188 \\ y &= 0.1882 & D &= 2.188 \\ a_{\text{th}} &= 2.188 & F &= 8.228 \end{aligned}$$

Then, we write the balanced reaction equation as

The air-fuel ratio is determined by taking the ratio of the mass of the air to the mass of the fuel,

$$\begin{aligned} \text{AF} &= \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{(2.188 \times 4.76 \text{ kmol})(29 \text{ kg/kmol})}{(0.8118 \text{ kmol})(12 + 4 \times 1) \text{ kg/kmol} + (0.1882 \text{ kmol})(2 \times 12 + 6 \times 1 + 16) \text{ kg/kmol}} \\ &= 13.94 \text{ kg air/kg fuel} \end{aligned}$$

Then, the required flow rate of air becomes

$$\dot{m}_{\text{air}} = \text{AF} \dot{m}_{\text{fuel}} = (13.94)(10 \text{ kg/s}) = \mathbf{139.4 \text{ kg/s}}$$

15-26 The volumetric fractions of the constituents of a certain natural gas are given. The AF ratio is to be determined if this gas is burned with the stoichiometric amount of dry air.

Assumptions 1 Combustion is complete. **2** The combustion products contain CO_2 , H_2O , and N_2 only.

Properties The molar masses of C, H_2 , N_2 , O_2 , and air are 12 kg/kmol, 2 kg/kmol, 28 kg/kmol, 32 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis Considering 1 kmol of fuel, the combustion equation can be written as

The unknown coefficients in the above equation are determined from mass balances,

$$\text{C: } 0.65 + 0.06 = x \quad \longrightarrow x = 0.71$$

$$\text{H: } 0.65 \times 4 + 0.08 \times 2 = 2y \quad \longrightarrow y = 1.38$$

$$\text{O}_2: 0.03 + 0.06 + a_{\text{th}} = x + y/2 \quad \longrightarrow a_{\text{th}} = 1.31$$

$$\text{N}_2: 0.18 + 3.76a_{\text{th}} = z \quad \longrightarrow z = 5.106$$

Thus,

The air-fuel ratio for this reaction is determined by taking the ratio of the mass of the air to the mass of the fuel,

$$m_{\text{air}} = (1.31 \times 4.76 \text{ kmol})(29 \text{ kg/kmol}) = 180.8 \text{ kg}$$

$$m_{\text{fuel}} = (0.65 \times 16 + 0.08 \times 2 + 0.18 \times 28 + 0.03 \times 32 + 0.06 \times 44) \text{ kg} = 19.2 \text{ kg}$$

and

$$\text{AF}_{\text{th}} = \frac{m_{\text{air,th}}}{m_{\text{fuel}}} = \frac{180.8 \text{ kg}}{19.2 \text{ kg}} = \mathbf{9.42 \text{ kg air/kg fuel}}$$

15-27 The composition of a certain natural gas is given. The gas is burned with stoichiometric amount of moist air. The AF ratio is to be determined.

Assumptions 1 Combustion is complete. **2** The combustion products contain CO_2 , H_2O , and N_2 only.

Properties The molar masses of C, H_2 , N_2 , O_2 , and air are 12 kg/kmol, 2 kg/kmol, 28 kg/kmol, 32 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis The fuel is burned completely with the stoichiometric amount of air, and thus the products will contain only H_2O , CO_2 and N_2 , but no free O_2 . The moisture in the air does not react with anything; it simply shows up as additional H_2O in the products. Therefore, we can simply balance the combustion equation using dry air, and then add the moisture to both sides of the equation. Considering 1 kmol of fuel, the combustion equation can be written as

The unknown coefficients in the above equation are determined from mass balances,

$$\text{C: } 0.65 + 0.06 = x \longrightarrow x = 0.71$$

$$\text{H: } 0.65 \times 4 + 0.08 \times 2 = 2y \longrightarrow y = 1.38$$

$$\text{O}_2: 0.03 + 0.06 + a_{\text{th}} = x + y/2 \longrightarrow a_{\text{th}} = 1.31$$

$$\text{N}_2: 0.18 + 3.76a_{\text{th}} = z \longrightarrow z = 5.106$$

Thus,

Next we determine the amount of moisture that accompanies $4.76a_{\text{th}} = (4.76)(1.31) = 6.24$ kmol of dry air. The partial pressure of the moisture in the air is

$$P_{v,\text{in}} = \phi_{\text{air}} P_{\text{sat}@25^\circ\text{C}} = (0.70)(3.1698 \text{ kPa}) = 2.219 \text{ kPa}$$

Assuming ideal gas behavior, the number of moles of the moisture in the air ($N_{v,\text{in}}$) is determined to be

$$N_{v,\text{in}} = \left(\frac{P_{v,\text{in}}}{P_{\text{total}}} \right) N_{\text{total}} = \left(\frac{2.219 \text{ kPa}}{101.325 \text{ kPa}} \right) (6.24 + N_{v,\text{in}}) \longrightarrow N_{v,\text{air}} = 0.1396 \text{ kmol}$$

The balanced combustion equation is obtained by substituting the coefficients determined earlier and adding 0.17 kmol of H_2O to both sides of the equation,

The air-fuel ratio for this reaction is determined by taking the ratio of the mass of the air to the mass of the fuel,

$$m_{\text{air}} = (1.31 \times 4.76 \text{ kmol})(29 \text{ kg/kmol}) + (0.1396 \text{ kmol} \times 18 \text{ kg/kmol}) = 183.3 \text{ kg}$$

$$m_{\text{fuel}} = (0.65 \times 16 + 0.08 \times 2 + 0.18 \times 28 + 0.03 \times 32 + 0.06 \times 44) \text{ kg} = 19.20 \text{ kg}$$

and

$$\text{AF}_{\text{th}} = \frac{m_{\text{air,th}}}{m_{\text{fuel}}} = \frac{183.3 \text{ kg}}{19.20 \text{ kg}} = \mathbf{9.55 \text{ kg air/kg fuel}}$$

15-28 The composition of a gaseous fuel is given. It is burned with 130 percent theoretical air. The AF ratio and the fraction of water vapor that would condense if the product gases were cooled are to be determined.

Assumptions 1 Combustion is complete. **2** The combustion products contain CO_2 , H_2O , O_2 , and N_2 only.

Properties The molar masses of C, H_2 , N_2 , and air are 12 kg/kmol, 2 kg/kmol, 28 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis (a) The fuel is burned completely with excess air, and thus the products will contain H_2O , CO_2 , N_2 , and some free O_2 . Considering 1 kmol of fuel, the combustion equation can be written as

The unknown coefficients in the above equation are determined from mass balances,

$$\text{C: } 0.45 = x \quad \longrightarrow x = 0.45$$

$$\text{H: } 0.45 \times 4 + 0.35 \times 2 = 2y \quad \longrightarrow y = 1.2$$

$$\text{O}_2: 1.3a_{\text{th}} = x + y/2 + 0.3a_{\text{th}} \quad \longrightarrow a_{\text{th}} = 1.05$$

$$\text{N}_2: 0.20 + 3.76 \times 1.3a_{\text{th}} = z \quad \longrightarrow z = 5.332$$

Thus,

The air-fuel ratio for the this reaction is determined by taking the ratio of the mass of the air to the mass of the fuel,

$$m_{\text{air}} = (1.365 \times 4.76 \text{ kmol})(29 \text{ kg/kmol}) = 188.4 \text{ kg}$$

$$m_{\text{fuel}} = (0.45 \times 16 + 0.35 \times 2 + 0.2 \times 28) \text{ kg} = 13.5 \text{ kg}$$

and

$$\text{AF} = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{188.4 \text{ kg}}{13.5 \text{ kg}} = \mathbf{13.96 \text{ kg air/kg fuel}}$$

(b) For each kmol of fuel burned, $0.45 + 1.2 + 0.315 + 5.332 = 7.297$ kmol of products are formed, including 1.2 kmol of H_2O . Assuming that the dew-point temperature of the products is above 25°C , some of the water vapor will condense as the products are cooled to 25°C . If N_w kmol of H_2O condenses, there will be $1.2 - N_w$ kmol of water vapor left in the products. The mole number of the products in the gas phase will also decrease to $7.297 - N_w$ as a result. Treating the product gases (including the remaining water vapor) as ideal gases, N_w is determined by equating the mole fraction of the water vapor to its pressure fraction,

$$\frac{N_w}{N_{\text{prod gas}}} = \frac{P_w}{P_{\text{prod}}} \longrightarrow \frac{1.2 - N_w}{7.297 - N_w} = \frac{3.1698 \text{ kPa}}{101.325 \text{ kPa}} \longrightarrow N_w = 1.003 \text{ kmol}$$

since $P_w = P_{\text{sat}} @ 25^\circ\text{C} = 3.1698 \text{ kPa}$. Thus the fraction of water vapor that condenses is

$$1.003/1.2 = 0.836 \text{ or } \mathbf{84\%}.$$

15-29 Problem 15-28 is reconsidered. The effects of varying the percentages of CH₄, H₂ and N₂ making up the fuel and the product gas temperature are to be studied.

Analysis The problem is solved using EES, and the solution is given below.

Let's modify this problem to include the fuels butane, ethane, methane, and propane in pull down menu. Adiabatic Combustion of fuel C_nH_m entering at T_{fuel} with Stoichiometric Air at T_{air}:
 Reaction: $aC_xH_y + bH_2 + cN_2 + (a*y/4 + a*x + b/2) (Theo_air/100) (O_2 + 3.76 N_2)$
 $\leftrightarrow a*xCO_2 + ((a*y/2) + b) H_2O + (c + 3.76 (a*y/4 + a*x + b/2) (Theo_air/100)) N_2 + (a*y/4 + a*x + b/2) (Theo_air/100 - 1) O_2$

T_{prod} is the product gas temperature.

Theo_{air} is the % theoretical air. "

15-30 Methane is burned with dry air. The volumetric analysis of the products is given. The AF ratio and the percentage of theoretical air used are to be determined.

Assumptions 1 Combustion is complete. **2** The combustion products contain CO_2 , CO , H_2O , O_2 , and N_2 only.

Properties The molar masses of C, H_2 , and air are 12 kg/kmol, 2 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis Considering 100 kmol of dry products, the combustion equation can be written as

The unknown coefficients x , a , and b are determined from mass balances,

$$\text{N}_2 : 3.76a = 83.23 \longrightarrow a = 22.14$$

$$\text{C} : x = 5.20 + 0.33 \longrightarrow x = 5.53$$

$$\text{H} : 4x = 2b \longrightarrow b = 11.06$$

$$(\text{Check } \text{O}_2 : a = 5.20 + 0.165 + 11.24 + b/2 \longrightarrow 22.14 = 22.14)$$

Thus,

The combustion equation for 1 kmol of fuel is obtained by dividing the above equation by 5.53,

(a) The air-fuel ratio is determined from its definition,

$$\text{AF} = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{(4.0 \times 4.76 \text{ kmol})(29 \text{ kg/kmol})}{(1 \text{ kmol})(12 \text{ kg/kmol}) + (2 \text{ kmol})(2 \text{ kg/kmol})} = \mathbf{34.5 \text{ kg air/kg fuel}}$$

(b) To find the percent theoretical air used, we need to know the theoretical amount of air, which is determined from the theoretical combustion equation of the fuel,

$$\text{O}_2 : a_{\text{th}} = 1 + 1 \longrightarrow a_{\text{th}} = 2.0$$

Then,

$$\text{Percent theoretical air} = \frac{m_{\text{air,act}}}{m_{\text{air,th}}} = \frac{N_{\text{air,act}}}{N_{\text{air,th}}} = \frac{(4.0)(4.76) \text{ kmol}}{(2.0)(4.76) \text{ kmol}} = \mathbf{200\%}$$

15-31 Octane is burned with dry air. The volumetric fractions of the products are given. The AF ratio and the percentage of theoretical air used are to be determined.

Assumptions 1 Combustion is complete. **2** The combustion products contain CO_2 , CO , H_2O , O_2 , and N_2 only.

Properties The molar masses of C, H_2 , and air are 12 kg/kmol, 2 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis Considering 100 kmol of dry products, the combustion equation can be written as

The unknown coefficients x , a , and b are determined from mass balances,

$$\text{N}_2 : 3.76a = 83.12 \longrightarrow a = 22.11$$

$$\text{C} : 8x = 9.21 + 0.61 \longrightarrow x = 1.23$$

$$\text{H} : 18x = 2b \longrightarrow b = 11.07$$

$$(\text{Check } \text{O}_2 : a = 9.21 + 0.305 + 7.06 + b/2 \longrightarrow 22.11 \cong 22.10)$$

Thus,

The combustion equation for 1 kmol of fuel is obtained by dividing the above equation by 1.23,

(a) The air-fuel ratio is determined by taking the ratio of the mass of the air to the mass of the fuel,

$$\text{AF} = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{(18.0 \times 4.76 \text{ kmol})(29 \text{ kg/kmol})}{(8 \text{ kmol})(12 \text{ kg/kmol}) + (9 \text{ kmol})(2 \text{ kg/kmol})} = \mathbf{21.8 \text{ kg air/kg fuel}}$$

(b) To find the percent theoretical air used, we need to know the theoretical amount of air, which is determined from the theoretical combustion equation of the fuel,

$$\text{O}_2 : a_{\text{th}} = 8 + 4.5 \longrightarrow a_{\text{th}} = 12.5$$

Then,

$$\text{Percent theoretical air} = \frac{m_{\text{air,act}}}{m_{\text{air,th}}} = \frac{N_{\text{air,act}}}{N_{\text{air,th}}} = \frac{(18.0)(4.76) \text{ kmol}}{(12.5)(4.76) \text{ kmol}} = \mathbf{144\%}$$

15-32 n-Octane is burned with 60% excess air. The combustion is incomplete. The mole fractions of products and the dew-point temperature of the water vapor in the products are to be determined.

Assumptions 1 Combustion is complete. 2 The combustion products contain CO_2 , CO , H_2O , O_2 , and N_2 only.

Properties The molar masses of C, H_2 , O_2 , N_2 and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, 28 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis The combustion reaction for stoichiometric air is

The combustion equation with 60% excess air and incomplete combustion is

The coefficient for CO is determined from a mass balance,

$$\text{O}_2 \text{ balance: } 1.6 \times 12.5 = 0.85 \times 8 + 0.5 \times 0.15 \times 8 + 0.5 \times 9 + x \longrightarrow x = 8.100$$

Substituting,

The mole fractions of the products are

$$N_{\text{prod}} = 6.8 + 1.2 + 9 + 8.1 + 75.2 = 100.3 \text{ kmol}$$

$$y_{\text{CO}_2} = \frac{N_{\text{CO}_2}}{N_{\text{prod}}} = \frac{6.8 \text{ kmol}}{100.3 \text{ kmol}} = \mathbf{0.0678}$$

$$y_{\text{CO}} = \frac{N_{\text{CO}}}{N_{\text{prod}}} = \frac{1.2 \text{ kmol}}{100.3 \text{ kmol}} = \mathbf{0.0120}$$

$$y_{\text{H}_2\text{O}} = \frac{N_{\text{H}_2\text{O}}}{N_{\text{prod}}} = \frac{9 \text{ kmol}}{100.3 \text{ kmol}} = \mathbf{0.0897}$$

$$y_{\text{O}_2} = \frac{N_{\text{O}_2}}{N_{\text{prod}}} = \frac{8.1 \text{ kmol}}{100.3 \text{ kmol}} = \mathbf{0.0808}$$

$$y_{\text{N}_2} = \frac{N_{\text{N}_2}}{N_{\text{prod}}} = \frac{75.2 \text{ kmol}}{100.3 \text{ kmol}} = \mathbf{0.7498}$$

The dew-point temperature of a gas-vapor mixture is the saturation temperature of the water vapor in the product gases corresponding to its partial pressure. That is,

$$P_v = \left(\frac{N_v}{N_{\text{prod}}} \right) P_{\text{prod}} = \left(\frac{9 \text{ kmol}}{100.3 \text{ kmol}} \right) (101.325 \text{ kPa}) = 9.092 \text{ kPa}$$

Thus,

$$T_{\text{dp}} = T_{\text{sat}@9.092\text{kPa}} = \mathbf{44.0^\circ\text{C}} \quad (\text{Table A-5 or EES})$$

15-33 Methyl alcohol is burned with 100% excess air. The combustion is incomplete. The balanced chemical reaction is to be written and the air-fuel ratio is to be determined.

Assumptions 1 Combustion is incomplete. 2 The combustion products contain CO_2 , CO , H_2O , O_2 , and N_2 only.

Properties The molar masses of C, H_2 , O_2 , N_2 and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, 28 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis The balanced reaction equation for stoichiometric air is

The stoichiometric coefficient a_{th} is determined from an O_2 balance:

$$0.5 + a_{\text{th}} = 1 + 1 \longrightarrow a_{\text{th}} = 1.5$$

Substituting,

The reaction with 100% excess air and incomplete combustion can be written as

The coefficient for O_2 is determined from a mass balance,

$$\text{O}_2 \text{ balance: } 0.5 + 2 \times 1.5 = 0.6 + 0.2 + 1 + x \longrightarrow x = 1.7$$

Substituting,

The air-fuel mass ratio is

$$\text{AF} = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{(3 \times 4.76 \times 29) \text{ kg}}{(1 \times 32) \text{ kg}} = \frac{414.1 \text{ kg}}{32 \text{ kg}} = \mathbf{12.94 \text{ kg air/kg fuel}}$$

15-34 Ethyl alcohol is burned with stoichiometric amount of air. The combustion is incomplete. The apparent molecular weight of the products is to be determined.

Assumptions 1 Combustion is complete. 2 The combustion products contain CO_2 , CO , H_2O , OH , and N_2 only.

Properties The molar masses of C, H_2 , OH , N_2 and air are 12 kg/kmol, 2 kg/kmol, 17 kg/kmol, 28 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis The reaction with stoichiometric air is

where

$$0.5 + a_{th} = 2 + 1.5 \longrightarrow a_{th} = 3$$

Substituting,

The balanced reaction equation with incomplete combustion is

$$\text{O}_2 \text{ balance: } 0.5 + 3 = 1.8 + 0.05 + 3.15/2 + b \rightarrow b = 0.075$$

which can be written as

The total moles of the products is

$$N_m = 1.8 + 0.1 + 2.85 + 0.3 + 0.075 + 11.28 = 16.41 \text{ kmol}$$

The apparent molecular weight of the product gas is

$$M_m = \frac{m_m}{N_m} = \frac{(1.8 \times 44 + 0.1 \times 28 + 2.85 \times 18 + 0.3 \times 17 + 0.075 \times 32 + 11.28 \times 28) \text{ kg}}{16.41 \text{ kmol}} = \mathbf{27.84 \text{ kg/kmol}}$$

15-35 Coal whose mass percentages are specified is burned with 40% excess air. The air-fuel ratio and the apparent molecular weight of the product gas are to be determined.

Assumptions 1 Combustion is complete. **2** The combustion products contain CO_2 , CO , H_2O , SO_2 , and N_2 . **3** Combustion gases are ideal gases.

Properties The molar masses of C, H_2 , O_2 , S, and air are 12, 2, 32, 32, and 29 kg/kmol, respectively (Table A-1).

Analysis We consider 100 kg of coal for simplicity. Noting that the mass percentages in this case correspond to the masses of the constituents, the mole numbers of the constituent of the coal are determined to be

$$N_{\text{C}} = \frac{m_{\text{C}}}{M_{\text{C}}} = \frac{67.40 \text{ kg}}{12 \text{ kg/kmol}} = 5.617 \text{ kmol}$$

$$N_{\text{H}_2} = \frac{m_{\text{H}_2}}{M_{\text{H}_2}} = \frac{5.31 \text{ kg}}{2 \text{ kg/kmol}} = 2.655 \text{ kmol}$$

$$N_{\text{O}_2} = \frac{m_{\text{O}_2}}{M_{\text{O}_2}} = \frac{15.11 \text{ kg}}{32 \text{ kg/kmol}} = 0.4722 \text{ kmol}$$

$$N_{\text{N}_2} = \frac{m_{\text{N}_2}}{M_{\text{N}_2}} = \frac{1.44 \text{ kg}}{28 \text{ kg/kmol}} = 0.05143 \text{ kmol}$$

$$N_{\text{S}} = \frac{m_{\text{S}}}{M_{\text{S}}} = \frac{2.36 \text{ kg}}{32 \text{ kg/kmol}} = 0.07375 \text{ kmol}$$

67.40% C
5.31% H_2
15.11% O_2
1.44% N_2
2.36% S
8.38% ash (by mass)

The mole number of the mixture and the mole fractions are

$$N_m = 5.617 + 2.655 + 0.4722 + 0.05143 + 0.07375 = 8.869 \text{ kmol}$$

$$y_{\text{C}} = \frac{N_{\text{C}}}{N_m} = \frac{5.617 \text{ kmol}}{8.869 \text{ kmol}} = 0.6333$$

$$y_{\text{H}_2} = \frac{N_{\text{H}_2}}{N_m} = \frac{2.655 \text{ kmol}}{8.869 \text{ kmol}} = 0.2994$$

$$y_{\text{O}_2} = \frac{N_{\text{O}_2}}{N_m} = \frac{0.4722 \text{ kmol}}{8.869 \text{ kmol}} = 0.05323$$

$$y_{\text{N}_2} = \frac{N_{\text{N}_2}}{N_m} = \frac{0.05143 \text{ kmol}}{8.869 \text{ kmol}} = 0.00580$$

$$y_{\text{S}} = \frac{N_{\text{S}}}{N_m} = \frac{0.07375 \text{ kmol}}{8.869 \text{ kmol}} = 0.00832$$

Ash consists of the non-combustible matter in coal. Therefore, the mass of ash content that enters the combustion chamber is equal to the mass content that leaves. Disregarding this non-reacting component for simplicity, the combustion equation may be written as

According to the species balances,

$$\text{C balance : } x = 0.6333$$

$$\text{H}_2 \text{ balance : } y = 0.2994$$

$$\text{S balance : } z = 0.00832$$

$$\text{O}_2 \text{ balance :}$$

$$0.05323 + a_{\text{th}} = x + 0.5y + z$$

$$a_{\text{th}} = 0.6333 + 0.5 \times 0.2994 + 0.00832 - 0.05323 = 0.7381$$

$$\text{N}_2 \text{ balance : } k = 0.00580 + 1.4 \times 3.76a_{\text{th}} = 0.00580 + 1.4 \times 3.76 \times 0.7381 = 3.891$$

$$m = 0.4a_{\text{th}} = 0.4 \times 0.7381 = 0.2952$$

Substituting,

The total mass of the products is

$$m_{\text{total}} = 0.6333 \times 44 + 0.2994 \times 18 + 0.00832 \times 64 + 3.891 \times 28 + 0.2952 \times 32 = 152.2 \text{ kg}$$

The total mole number of the products is

$$N_m = 0.6333 + 0.2994 + 0.00832 + 3.891 + 0.2952 = 5.127 \text{ kmol}$$

The apparent molecular weight of the product gas is

$$M_m = \frac{m_m}{N_m} = \frac{152.2 \text{ kg}}{5.127 \text{ kmol}} = \mathbf{29.68 \text{ kg/kmol}}$$

The air-fuel mass ratio is then

$$\text{AF} = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{(1.033 \times 4.76 \times 29) \text{ kg}}{(0.6333 \times 12 + 0.2994 \times 2 + 0.05323 \times 32 + 0.00580 \times 28 + 0.00832 \times 32) \text{ kg}} \\ = \frac{142.6 \text{ kg}}{10.33 \text{ kg}} \\ = \mathbf{13.80 \text{ kg air/kg fuel}}$$

15-36 The composition of a certain coal is given. The coal is burned with 50 percent excess air. The AF ratio is to be determined.

Assumptions 1 Combustion is complete. **2** The combustion products contain CO_2 , H_2O , O_2 , N_2 , and ash only.

Properties The molar masses of C, H_2 , O_2 , and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis The composition of the coal is given on a mass basis, but we need to know the composition on a mole basis to balance the combustion equation. Considering 1 kg of coal, the numbers of mole of the each component are determined to be

$$\begin{aligned} N_{\text{C}} &= (m/M)_{\text{C}} = 0.82/12 = 0.0683 \text{ kmol} \\ N_{\text{H}_2\text{O}} &= (m/M)_{\text{H}_2\text{O}} = 0.05/18 = 0.0028 \text{ kmol} \\ N_{\text{H}_2} &= (m/M)_{\text{H}_2} = 0.02/2 = 0.01 \text{ kmol} \\ N_{\text{O}_2} &= (m/M)_{\text{O}_2} = 0.01/32 = 0.00031 \text{ kmol} \end{aligned}$$

Considering 1 kg of coal, the combustion equation can be written as

The unknown coefficients in the above equation are determined from mass balances,

$$\begin{aligned} \text{C: } 0.0683 &= x \longrightarrow x = 0.0683 \\ \text{H: } 0.0028 \times 2 + 0.01 \times 2 &= 2y \longrightarrow y = 0.0128 \\ \text{O}_2: 0.0028/2 + 0.00031 + 1.5a_{\text{th}} &= x + y/2 + 0.5a_{\text{th}} \longrightarrow a_{\text{th}} = 0.073 \end{aligned}$$

Thus,

The air-fuel ratio for the this reaction is determined by taking the ratio of the mass of the air to the mass of the coal, which is taken to be 1 kg,

$$\begin{aligned} m_{\text{air}} &= (0.1095 \times 4.76 \text{ kmol})(29 \text{ kg/kmol}) = 15.1 \text{ kg} \\ m_{\text{fuel}} &= 1 \text{ kg} \end{aligned}$$

and

$$\text{AF} = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{15.1 \text{ kg}}{1 \text{ kg}} = \mathbf{15.1 \text{ kg air/kg fuel}}$$

Enthalpy of Formation and Enthalpy of Combustion

15-37C Enthalpy of formation is the enthalpy of a substance due to its chemical composition. The enthalpy of formation is related to elements or compounds whereas the enthalpy of combustion is related to a particular fuel.

15-38C For combustion processes the enthalpy of reaction is referred to as the enthalpy of combustion, which represents the amount of heat released during a steady-flow combustion process.

15-39C The heating value is called the higher heating value when the H₂O in the products is in the liquid form, and it is called the lower heating value when the H₂O in the products is in the vapor form. The heating value of a fuel is equal to the absolute value of the enthalpy of combustion of that fuel.

15-40C No. The enthalpy of formation of N₂ is simply assigned a value of zero at the standard reference state for convenience.

15-41C 1 kmol of H₂. This is evident from the observation that when chemical bonds of H₂ are destroyed to form H₂O a large amount of energy is released.

15-42 The enthalpy of combustion of methane at a 25°C and 1 atm is to be determined using the data from Table A-26 and to be compared to the value listed in Table A-27.

Assumptions The water in the products is in the liquid phase.

Analysis The stoichiometric equation for this reaction is

Both the reactants and the products are at the standard reference state of 25°C and 1 atm. Also, N₂ and O₂ are stable elements, and thus their enthalpy of formation is zero. Then the enthalpy of combustion of CH₄ becomes

$$h_C = H_P - H_R = \sum N_P \bar{h}_{f,P}^\circ - \sum N_R \bar{h}_{f,R}^\circ = (N \bar{h}_f^\circ)_{\text{CO}_2} + (N \bar{h}_f^\circ)_{\text{H}_2\text{O}} - (N \bar{h}_f^\circ)_{\text{CH}_4}$$

Using \bar{h}_f° values from Table A-26,

$$\begin{aligned} h_C &= (1 \text{ kmol})(-393,520 \text{ kJ/kmol}) + (2 \text{ kmol})(-285,830 \text{ kJ/kmol}) \\ &\quad - (1 \text{ kmol})(-74,850 \text{ kJ/kmol}) \\ &= \mathbf{-890,330 \text{ kJ}} \text{ (per kmol CH}_4\text{)} \end{aligned}$$

The listed value in Table A-27 is -890,868 kJ/kmol, which is almost identical to the calculated value. Since the water in the products is assumed to be in the liquid phase, this h_C value corresponds to the higher heating value of CH₄.

15-43  Problem 15-42 is reconsidered. The effect of temperature on the enthalpy of combustion is to be studied.

Analysis The problem is solved using EES, and the solution is given below.

```

15-44 The enthalpy of combustion of gaseous ethane at a 25°C and 1 atm is to be determined using the data from Table A-26 and to be compared to the value listed in Table A-27.

Assumptions The water in the products is in the liquid phase.

Analysis The stoichiometric equation for this reaction is

Both the reactants and the products are at the standard reference state of 25°C and 1 atm. Also, N₂ and O₂ are stable elements, and thus their enthalpy of formation is zero. Then the enthalpy of combustion of C₂H₆ becomes

$$h_C = H_P - H_R = \sum N_P \bar{h}_{f,P}^\circ - \sum N_R \bar{h}_{f,R}^\circ = (N\bar{h}_f^\circ)_{\text{CO}_2} + (N\bar{h}_f^\circ)_{\text{H}_2\text{O}} - (N\bar{h}_f^\circ)_{\text{C}_2\text{H}_6}$$

Using \bar{h}_f° values from Table A-26,

$$\begin{aligned} h_C &= (2 \text{ kmol})(-393,520 \text{ kJ/kmol}) + (3 \text{ kmol})(-285,830 \text{ kJ/kmol}) \\ &\quad - (1 \text{ kmol})(-84,680 \text{ kJ/kmol}) \\ &= \mathbf{-1,559,850 \text{ kJ}} \text{ (per kmol C}_2\text{H}_6) \end{aligned}$$

The listed value in Table A-27 is -1,560,633 kJ/kmol, which is almost identical to the calculated value. Since the water in the products is assumed to be in the liquid phase, this h_c value corresponds to the higher heating value of C₂H₆.

15-45 The enthalpy of combustion of liquid octane at a 25°C and 1 atm is to be determined using the data from Table A-26 and to be compared to the value listed in Table A-27.

Assumptions The water in the products is in the liquid phase.

Analysis The stoichiometric equation for this reaction is

Both the reactants and the products are at the standard reference state of 25°C and 1 atm. Also, N₂ and O₂ are stable elements, and thus their enthalpy of formation is zero. Then the enthalpy of combustion of C₈H₁₈ becomes

$$h_C = H_P - H_R = \sum N_P \bar{h}_{f,P}^\circ - \sum N_R \bar{h}_{f,R}^\circ = (N\bar{h}_f^\circ)_{\text{CO}_2} + (N\bar{h}_f^\circ)_{\text{H}_2\text{O}} - (N\bar{h}_f^\circ)_{\text{C}_8\text{H}_{18}}$$

Using \bar{h}_f° values from Table A-26,

$$\begin{aligned} h_C &= (8 \text{ kmol})(-393,520 \text{ kJ/kmol}) + (9 \text{ kmol})(-285,830 \text{ kJ/kmol}) \\ &\quad - (1 \text{ kmol})(-249,950 \text{ kJ/kmol}) \\ &= \mathbf{-5,470,680 \text{ kJ}} \end{aligned}$$

The listed value in Table A-27 is -5,470,523 kJ/kmol, which is almost identical to the calculated value. Since the water in the products is assumed to be in the liquid phase, this h_c value corresponds to the higher heating value of C₈H₁₈.

15-46 Ethane is burned with stoichiometric amount of air. The heat transfer is to be determined if both the reactants and products are at 25°C.

Assumptions The water in the products is in the vapor phase.

Analysis The stoichiometric equation for this reaction is

Since both the reactants and the products are at the standard reference state of 25°C and 1 atm, the heat transfer for this process is equal to enthalpy of combustion. Note that N₂ and O₂ are stable elements, and thus their enthalpy of formation is zero. Then,

$$Q = h_C = H_P - H_R = \sum N_P \bar{h}_{f,P}^\circ - \sum N_R \bar{h}_{f,R}^\circ = (N \bar{h}_f^\circ)_{\text{CO}_2} + (N \bar{h}_f^\circ)_{\text{H}_2\text{O}} - (N \bar{h}_f^\circ)_{\text{C}_2\text{H}_6}$$

Using \bar{h}_f° values from Table A-26,

$$\begin{aligned} Q = h_C &= (2 \text{ kmol})(-393,520 \text{ kJ/kmol}) + (3 \text{ kmol})(-241,820 \text{ kJ/kmol}) - (1 \text{ kmol})(-84,680 \text{ kJ/kmol}) \\ &= \mathbf{-1,427,820 \text{ kJ/kmol C}_2\text{H}_6} \end{aligned}$$

15-47 Ethane is burned with stoichiometric amount of air at 1 atm and 25°C. The minimum pressure of the products which will assure that the water in the products will be in vapor form is to be determined.

Assumptions The water in the products is in the vapor phase.

Analysis The stoichiometric equation for this reaction is

At the minimum pressure, the product mixture will be saturated with water vapor and

$$P_v = P_{\text{sat}@25^\circ\text{C}} = 3.1698 \text{ kPa}$$

The mole fraction of water in the products is

$$y_v = \frac{N_{\text{H}_2\text{O}}}{N_{\text{prod}}} = \frac{3 \text{ kmol}}{(2 + 3 + 13.16) \text{ kmol}} = 0.1652$$

The minimum pressure of the products is then

$$P_{\text{min}} = \frac{P_v}{y_v} = \frac{3.1698 \text{ kPa}}{0.1652} = \mathbf{19.2 \text{ kPa}}$$

15-48 The higher and lower heating values of liquid propane are to be determined and compared to the listed values.

Assumptions 1 Combustion is complete. **2** The combustion products contain CO_2 , H_2O , and N_2 . **3** Combustion gases are ideal gases.

Properties The molar masses of C, O_2 , H_2 , and air are 12, 32, 2, and 29 kg/kmol, respectively (Table A-1).

Analysis The combustion reaction with stoichiometric air is

Both the reactants and the products are taken to be at the standard reference state of 25°C and 1 atm for the calculation of heating values. The heat transfer for this process is equal to enthalpy of combustion. Note that N_2 and O_2 are stable elements, and thus their enthalpy of formation is zero. Then,

$$q = h_C = H_P - H_R = \sum N_P \bar{h}_{f,P}^\circ - \sum N_R \bar{h}_{f,R}^\circ = (N \bar{h}_f^\circ)_{\text{CO}_2} + (N \bar{h}_f^\circ)_{\text{H}_2\text{O}} - (N \bar{h}_f^\circ)_{\text{C}_3\text{H}_8}$$

The \bar{h}_f° of liquid propane is obtained by adding \bar{h}_{fg} of propane at 25°C to \bar{h}_f° of gas propane ($103,850 + 44.097 \times 335 = 118,620$ kJ/kmol). For the HHV, the water in the products is taken to be liquid. Then,

$$\begin{aligned} h_C &= (3 \text{ kmol})(-393,520 \text{ kJ/kmol}) + (4 \text{ kmol})(-285,830 \text{ kJ/kmol}) - (1 \text{ kmol})(-118,620 \text{ kJ/kmol}) \\ &= -2,205,260 \text{ kJ/kmol propane} \end{aligned}$$

The HHV of the liquid propane is

$$\text{HHV} = \frac{-h_C}{M_m} = \frac{2,205,260 \text{ kJ/kmol C}_3\text{H}_8}{44.097 \text{ kg/kmol C}_3\text{H}_8} = \mathbf{50,010 \text{ kJ/kg C}_3\text{H}_8}$$

The listed value from Table A-27 is **50,330 kJ/kg**. For the LHV, the water in the products is taken to be vapor. Then,

$$\begin{aligned} h_C &= (3 \text{ kmol})(-393,520 \text{ kJ/kmol}) + (4 \text{ kmol})(-241,820 \text{ kJ/kmol}) - (1 \text{ kmol})(-118,620 \text{ kJ/kmol}) \\ &= -2,029,220 \text{ kJ/kmol propane} \end{aligned}$$

The LHV of the propane is then

$$\text{LHV} = \frac{-h_C}{M_m} = \frac{2,029,220 \text{ kJ/kmol C}_3\text{H}_8}{44.097 \text{ kg/kmol C}_3\text{H}_8} = \mathbf{46,020 \text{ kJ/kg C}_3\text{H}_8}$$

The listed value from Table A-27 is **46,340 kJ/kg**. The calculated and listed values are practically identical.

15-49 The higher and lower heating values of coal from Illinois are to be determined.

Assumptions 1 Combustion is complete. **2** The combustion products contain CO_2 , CO , H_2O , SO_2 , and N_2 . **3** Combustion gases are ideal gases.

Properties The molar masses of C, H_2 , O_2 , S, and air are 12, 2, 32, 32, and 29 kg/kmol, respectively (Table A-1).

Analysis We consider 100 kg of coal for simplicity. Noting that the mass percentages in this case correspond to the masses of the constituents, the mole numbers of the constituent of the coal are determined to be

$$N_{\text{C}} = \frac{m_{\text{C}}}{M_{\text{C}}} = \frac{67.40 \text{ kg}}{12 \text{ kg/kmol}} = 5.617 \text{ kmol}$$

$$N_{\text{H}_2} = \frac{m_{\text{H}_2}}{M_{\text{H}_2}} = \frac{5.31 \text{ kg}}{2 \text{ kg/kmol}} = 2.655 \text{ kmol}$$

$$N_{\text{O}_2} = \frac{m_{\text{O}_2}}{M_{\text{O}_2}} = \frac{15.11 \text{ kg}}{32 \text{ kg/kmol}} = 0.4722 \text{ kmol}$$

$$N_{\text{N}_2} = \frac{m_{\text{N}_2}}{M_{\text{N}_2}} = \frac{1.44 \text{ kg}}{28 \text{ kg/kmol}} = 0.05143 \text{ kmol}$$

$$N_{\text{S}} = \frac{m_{\text{S}}}{M_{\text{S}}} = \frac{2.36 \text{ kg}}{32 \text{ kg/kmol}} = 0.07375 \text{ kmol}$$

67.40% C
5.31% H_2
15.11% O_2
1.44% N_2
2.36% S
8.38% ash (by mass)

The mole number of the mixture and the mole fractions are

$$N_m = 5.617 + 2.655 + 0.4722 + 0.05143 + 0.07375 = 8.869 \text{ kmol}$$

$$y_{\text{C}} = \frac{N_{\text{C}}}{N_m} = \frac{5.617 \text{ kmol}}{8.869 \text{ kmol}} = 0.6333$$

$$y_{\text{H}_2} = \frac{N_{\text{H}_2}}{N_m} = \frac{2.655 \text{ kmol}}{8.869 \text{ kmol}} = 0.2994$$

$$y_{\text{O}_2} = \frac{N_{\text{O}_2}}{N_m} = \frac{0.4722 \text{ kmol}}{8.869 \text{ kmol}} = 0.05323$$

$$y_{\text{N}_2} = \frac{N_{\text{N}_2}}{N_m} = \frac{0.05143 \text{ kmol}}{8.869 \text{ kmol}} = 0.00580$$

$$y_{\text{S}} = \frac{N_{\text{S}}}{N_m} = \frac{0.07375 \text{ kmol}}{8.869 \text{ kmol}} = 0.00832$$

Ash consists of the non-combustible matter in coal. Therefore, the mass of ash content that enters the combustion chamber is equal to the mass content that leaves. Disregarding this non-reacting component for simplicity, the combustion equation may be written as

According to the species balances,

$$\text{C balance: } x = 0.6333$$

$$\text{H}_2 \text{ balance: } y = 0.2994$$

$$\text{S balance: } z = 0.00832$$

$$\text{O}_2 \text{ balance:}$$

$$0.05323 + a_{\text{th}} = x + 0.5y + z$$

$$a_{\text{th}} = 0.6333 + 0.5 \times 0.2994 + 0.00832 - 0.05323 = 0.7381$$

$$\text{N}_2 \text{ balance: } k = 0.00580 + 3.76a_{\text{th}} = 0.00580 + 3.76 \times 0.7381 = 2.781$$

Substituting,

Both the reactants and the products are taken to be at the standard reference state of 25°C and 1 atm for the calculation of heating values. The heat transfer for this process is equal to enthalpy of combustion. Note that C, S, H₂, N₂ and O₂ are stable elements, and thus their enthalpy of formation is zero. Then,

$$q = h_C = H_P - H_R = \sum N_P \bar{h}_{f,P}^\circ - \sum N_R \bar{h}_{f,R}^\circ = (N\bar{h}_f^\circ)_{\text{CO}_2} + (N\bar{h}_f^\circ)_{\text{H}_2\text{O}} + (N\bar{h}_f^\circ)_{\text{SO}_2}$$

For the HHV, the water in the products is taken to be liquid. Then,

$$h_C = (0.6333 \text{ kmol})(-393,520 \text{ kJ/kmol}) + (0.2994 \text{ kmol})(-285,830 \text{ kJ/kmol}) \\ + (0.00832 \text{ kmol})(-297,100 \text{ kJ/kmol}) \\ = -337,270 \text{ kJ/kmol coal}$$

The apparent molecular weight of the coal is

$$M_m = \frac{m_m}{N_m} = \frac{(0.6333 \times 12 + 0.2994 \times 2 + 0.05323 \times 32 + 0.00580 \times 28 + 0.00832 \times 32) \text{ kg}}{(0.6333 + 0.2994 + 0.05323 + 0.00580 + 0.00832) \text{ kmol}} \\ = \frac{10.33 \text{ kg}}{1.000 \text{ kmol}} = 10.33 \text{ kg/kmol coal}$$

The HHV of the coal is then

$$\text{HHV} = \frac{-h_C}{M_m} = \frac{337,270 \text{ kJ/kmol coal}}{10.33 \text{ kg/kmol coal}} = \mathbf{32,650 \text{ kJ/kg coal}}$$

For the LHV, the water in the products is taken to be vapor. Then,

$$h_C = (0.6333 \text{ kmol})(-393,520 \text{ kJ/kmol}) + (0.2994 \text{ kmol})(-241,820 \text{ kJ/kmol}) \\ + (0.00832 \text{ kmol})(-297,100 \text{ kJ/kmol}) \\ = -324,090 \text{ kJ/kmol coal}$$

The LHV of the coal is then

$$\text{LHV} = \frac{-h_C}{M_m} = \frac{324,090 \text{ kJ/kmol coal}}{10.33 \text{ kg/kmol coal}} = \mathbf{31,370 \text{ kJ/kg coal}}$$

First Law Analysis of Reacting Systems

15-50C The heat transfer will be the same for all cases. The excess oxygen and nitrogen enters and leaves the combustion chamber at the same state, and thus has no effect on the energy balance.

15-51C For case (b), which contains the maximum amount of nonreacting gases. This is because part of the chemical energy released in the combustion chamber is absorbed and transported out by the nonreacting gases.

15-52C In this case $\Delta U + W_b = \Delta H$, and the conservation of energy relation reduces to the form of the steady-flow energy relation.

15-53 Acetylene gas is burned with 20 percent excess air during a steady-flow combustion process. The AF ratio and the heat transfer are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 Combustion is complete.

Properties The molar masses of C_2H_2 and air are 26 kg/kmol and 29 kg/kmol, respectively (Table A-1).

Analysis The fuel is burned completely with the excess air, and thus the products will contain only CO_2 , H_2O , N_2 , and some free O_2 . Considering 1 kmol of C_2H_2 , the combustion equation can be written as

where a_{th} is the stoichiometric coefficient and is determined from the O_2 balance,

$$1.2a_{th} = 2 + 0.5 + 0.2a_{th} \longrightarrow a_{th} = 2.5$$

Thus,

$$(a) \quad AF = \frac{m_{air}}{m_{fuel}} = \frac{(3 \times 4.76 \text{ kmol})(29 \text{ kg/kmol})}{(2 \text{ kmol})(12 \text{ kg/kmol}) + (1 \text{ kmol})(2 \text{ kg/kmol})} = \mathbf{15.9 \text{ kg air/kg fuel}}$$

(b) The heat transfer for this combustion process is determined from the energy balance $E_{in} - E_{out} = \Delta E_{system}$ applied on the combustion chamber with $W = 0$. It reduces to

$$-Q_{out} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R \bar{h}_{f,R}^\circ$$

since all of the reactants are at $25^\circ C$. Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298 \text{ K}}$ kJ/kmol	$\bar{h}_{1500 \text{ K}}$ kJ/kmol
C_2H_2	226,730	---	---
O_2	0	8682	49,292
N_2	0	8669	47,073
$H_2O(g)$	-241,820	9904	57,999
CO_2	-393,520	9364	71,078

Thus,

$$\begin{aligned} -Q_{out} &= (2)(-393,520 + 71,078 - 9364) + (1)(-241,820 + 57,999 - 9904) + (0.5)(0 + 49,292 - 8682) \\ &\quad + (11.28)(0 + 47,073 - 8669) - (1)(226,730) - 0 - 0 \\ &= -630,565 \text{ kJ/kmol } C_2H_2 \end{aligned}$$

or

$$Q_{out} = \mathbf{630,565 \text{ kJ / kmol } } C_2H_2$$

15-54E Liquid propane is burned with 150 percent excess air during a steady-flow combustion process. The mass flow rate of air and the rate of heat transfer from the combustion chamber are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 Combustion is complete.

Properties The molar masses of propane and air are 44 lbm/lbmol and 29 lbm/lbmol, respectively (Table A-1E).

Analysis The fuel is burned completely with the excess air, and thus the products will contain only CO_2 , H_2O , N_2 , and some free O_2 . Considering 1 kmol of C_3H_8 , the combustion equation can be written as

where a_{th} is the stoichiometric coefficient and is determined from the O_2 balance,

$$2.5a_{\text{th}} = 3 + 2 + 1.5a_{\text{th}} \longrightarrow a_{\text{th}} = 5$$

Thus,

(a) The air-fuel ratio for this combustion process is

$$\text{AF} = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{(12.5 \times 4.76 \text{ lbmol})(29 \text{ lbm/lbmol})}{(3 \text{ lbmol})(12 \text{ lbm/lbmol}) + (4 \text{ lbmol})(2 \text{ lbm/lbmol})} = 39.2 \text{ lbm air/lbm fuel}$$

Thus, $\dot{m}_{\text{air}} = (\text{AF})(\dot{m}_{\text{fuel}}) = (39.2 \text{ lbm air/lbm fuel})(0.75 \text{ lbm fuel/min}) = \mathbf{29.4 \text{ lbm air/min}}$

(b) The heat transfer for this combustion process is determined from the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $W = 0$. It reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° Btu/lbmol	$\bar{h}_{500\text{R}}$ Btu/lbmol	$\bar{h}_{537\text{R}}$ Btu/lbmol	$\bar{h}_{1800\text{R}}$ Btu/lbmol
$\text{C}_3\text{H}_8(\ell)$	-51,160	---	---	---
O_2	0	3466.2	3725.1	13,485.8
N_2	0	3472.2	3729.5	12,956.3
CO_2	-169,300	---	4027.5	18,391.5
$\text{H}_2\text{O}(g)$	-104,040	---	4258.0	15,433.0

The \bar{h}_f° of liquid propane is obtained by adding the \bar{h}_{fg} of propane at 77°F to the \bar{h}_f° of gas propane. Substituting,

$$\begin{aligned} -Q_{\text{out}} &= (3)(-169,300 + 18,391.5 - 4027.5) + (4)(-104,040 + 15,433 - 4258) + (7.5)(0 + 13,485.8 - 3725.1) \\ &\quad + (47)(0 + 12,956.3 - 3729.5) - (1)(-51,160 + h_{537} - h_{537}) - (12.5)(0 + 3466.2 - 3725.1) \\ &\quad - (47)(0 + 3472.2 - 3729.5) \\ &= -262,773 \text{ Btu/lbmol C}_3\text{H}_8 \end{aligned}$$

or $Q_{\text{out}} = 262,773 \text{ Btu/lbmol C}_3\text{H}_8$

Then the rate of heat transfer for a mass flow rate of 0.75 kg/min for the propane becomes

$$\dot{Q}_{\text{out}} = \dot{N} Q_{\text{out}} = \left(\frac{\dot{m}}{N} \right) Q_{\text{out}} = \left(\frac{0.75 \text{ lbm/min}}{44 \text{ lbm/lbmol}} \right) (262,773 \text{ Btu/lbmol}) = \mathbf{4479 \text{ Btu/min}}$$

15-55 Propane is burned with an air-fuel ratio of 25. The heat transfer per kilogram of fuel burned when the temperature of the products is such that liquid water just begins to form in the products is to be determined.

Assumptions 1 Steady operating conditions exist. **2** Air and combustion gases are ideal gases. **3** Kinetic and potential energies are negligible. **4** Combustion is complete. **5** The reactants are at 25°C and 1 atm. **6** The fuel is in vapor phase.

Properties The molar masses of propane and air are 44 kg/kmol and 29 kg/kmol, respectively (Table A-1).

Analysis The mass of air per kmol of fuel is

$$m_{\text{air}} = (\text{AF})m_{\text{fuel}} \\ = (25 \text{ kg air/kg fuel})(1 \times 44 \text{ kg/kmol fuel}) = 1100 \text{ kg air/kmol fuel}$$

The mole number of air per kmol of fuel is then

$$N_{\text{air}} = \frac{m_{\text{air}}}{M_{\text{air}}} = \frac{1100 \text{ kg air/kmol fuel}}{29 \text{ kg air/kmol air}} = 37.93 \text{ kmol air/kmol fuel}$$

The combustion equation can be written as

The coefficient for O₂ is obtained from O₂ balance:

$$(37.93/4.76) = 3 + 2 + x \longrightarrow x = 2.968$$

The mole fraction of water in the products is

$$y_v = \frac{N_{\text{H}_2\text{O}}}{N_{\text{prod}}} = \frac{4 \text{ kmol}}{(3 + 4 + 2.968 + 29.96) \text{ kmol}} = \frac{4 \text{ kmol}}{39.93 \text{ kmol}} = 0.1002$$

The partial pressure of water vapor at 1 atm total pressure is

$$P_v = y_v P = (0.1002)(101.325 \text{ kPa}) = 10.15 \text{ kPa}$$

When this mixture is at the dew-point temperature, the water vapor pressure is the same as the saturation pressure. Then,

$$T_{\text{dp}} = T_{\text{sat}@10.15\text{kPa}} = 46.1^\circ\text{C} = 319.1 \text{ K} \approx 320 \text{ K}$$

We obtain properties at 320 K (instead of 319.1 K) to avoid iterations in the ideal gas tables. The heat transfer for this combustion process is determined from the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with

$W = 0$. It reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° , kJ/kmol	$\bar{h}_{298\text{K}}$, kJ/kmol	$\bar{h}_{320\text{K}}$, kJ/kmol
C ₃ H ₈	-103,850	---	---
O ₂	0	8682	9325
N ₂	0	8669	9306
H ₂ O (g)	-241,820	9904	10,639
CO ₂	-393,520	9364	10,186

Substituting,

$$-\bar{Q}_{\text{out}} = (3)(-393,520 + 10,186 - 9364) + (4)(-241,820 + 10,639 - 9904) + (2.968)(0 + 9325 - 8682) \\ + (29.96)(0 + 9306 - 8669) - (1)(-103,850) - 0 \\ = -2,017,590 \text{ kJ/kmol C}_3\text{H}_8$$

or $\bar{Q}_{\text{out}} = 2,017,590 \text{ kJ/kmol C}_3\text{H}_8$

Then the heat transfer per kg of fuel is

$$Q_{\text{out}} = \frac{\bar{Q}_{\text{out}}}{M_{\text{fuel}}} = \frac{2,017,590 \text{ kJ/kmol fuel}}{44 \text{ kg/kmol}} = \mathbf{45,850 \text{ kJ/kg C}_3\text{H}_8}$$

15-56 Hydrogen is burned completely during a steady-flow combustion process. The heat transfer from the combustion chamber is to be determined for two cases.

Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 Combustion is complete.

Analysis The H_2 is burned completely with the stoichiometric amount of air, and thus the products will contain only H_2O and N_2 , but no free O_2 . Considering 1 kmol of H_2 , the theoretical combustion equation can be written as

where a_{th} is determined from the O_2 balance to be $a_{\text{th}} = 0.5$.
Substituting,

The heat transfer for this combustion process is determined from the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $W = 0$. It reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R = \sum N_P \bar{h}_{f,P}^\circ - \sum N_R \bar{h}_{f,R}^\circ$$

since both the reactants and the products are at 25°C and both the air and the combustion gases can be treated as ideal gases. From the tables,

Substance	\bar{h}_f° kJ/kmol
H_2	0
O_2	0
N_2	0
$\text{H}_2\text{O} (\ell)$	-285,830

Substituting,

$$-Q_{\text{out}} = (1)(-285,830) + 0 - 0 - 0 - 0 = -285,830 \text{ kJ / kmol H}_2$$

or

$$Q_{\text{out}} = \mathbf{285,830 \text{ kJ / kmol H}_2}$$

If combustion is achieved with 50% excess air, the answer would still be the same since it would enter and leave at 25°C , and absorb no energy.

15-57 n-Octane is burned with 80 percent excess air. The heat transfer per kilogram of fuel burned for a product temperature of 217°C is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 Combustion is complete. 5 The fuel is in vapor phase.

Properties The molar masses of propane and air are 44 kg/kmol and 29 kg/kmol, respectively (Table A-1).

Analysis The combustion reaction for stoichiometric air is

The combustion equation with 80% excess air is

or

The heat transfer for this combustion process is determined from the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $W = 0$. It reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{K}}$ kJ/kmol	$\bar{h}_{490\text{K}}$ kJ/kmol
$\text{C}_8\text{H}_{18} (g)$	-208,450	---	---
O_2	0	8682	14,460
N_2	0	8669	14,285
$\text{H}_2\text{O} (g)$	-241,820	9904	16,477
CO_2	-393,520	9364	17,232

Substituting,

$$\begin{aligned} -\bar{Q}_{\text{out}} &= (8)(-393,520 + 17,232 - 9364) + (9)(-241,820 + 16,477 - 9904) + (10)(0 + 14,460 - 8682) \\ &\quad + (84.6)(0 + 14,285 - 8669) - (1)(-208,450) - 0 - 0 \\ &= -4,239,880 \text{ kJ/kmol C}_8\text{H}_{18} \end{aligned}$$

or

$$\bar{Q}_{\text{out}} = 4,461,095 \text{ kJ/kmol C}_8\text{H}_{18}$$

Then the heat transfer per kg of fuel is

$$Q_{\text{out}} = \frac{\bar{Q}_{\text{out}}}{M_{\text{fuel}}} = \frac{4,461,095 \text{ kJ/kmol fuel}}{114 \text{ kg/kmol}} = \mathbf{39,130 \text{ kJ/kg C}_8\text{H}_{18}}$$

15-58 A certain coal is burned steadily with 40% excess air. The heat transfer for a given product temperature is to be determined.

Assumptions 1 Combustion is complete. 2 The combustion products contain CO_2 , CO , H_2O , SO_2 , and N_2 . 3 Combustion gases are ideal gases.

Properties The molar masses of C, H_2 , N_2 , O_2 , S, and air are 12, 2, 28, 32, 32, and 29 kg/kmol, respectively (Table A-1).

Analysis We consider 100 kg of coal for simplicity. Noting that the mass percentages in this case correspond to the masses of the constituents, the mole numbers of the constituent of the coal are determined to be

$$N_{\text{C}} = \frac{m_{\text{C}}}{M_{\text{C}}} = \frac{39.25 \text{ kg}}{12 \text{ kg/kmol}} = 3.271 \text{ kmol}$$

$$N_{\text{H}_2} = \frac{m_{\text{H}_2}}{M_{\text{H}_2}} = \frac{6.93 \text{ kg}}{2 \text{ kg/kmol}} = 3.465 \text{ kmol}$$

$$N_{\text{O}_2} = \frac{m_{\text{O}_2}}{M_{\text{O}_2}} = \frac{41.11 \text{ kg}}{32 \text{ kg/kmol}} = 1.285 \text{ kmol}$$

$$N_{\text{N}_2} = \frac{m_{\text{N}_2}}{M_{\text{N}_2}} = \frac{0.72 \text{ kg}}{28 \text{ kg/kmol}} = 0.0257 \text{ kmol}$$

$$N_{\text{S}} = \frac{m_{\text{S}}}{M_{\text{S}}} = \frac{0.79 \text{ kg}}{32 \text{ kg/kmol}} = 0.0247 \text{ kmol}$$

39.25% C
6.93% H_2
41.11% O_2
0.72% N_2
0.79% S
11.20% ash (by mass)

The mole number of the mixture and the mole fractions are

$$N_m = 3.271 + 3.465 + 1.285 + 0.0257 + 0.0247 = 8.071 \text{ kmol}$$

$$y_{\text{C}} = \frac{N_{\text{C}}}{N_m} = \frac{3.271 \text{ kmol}}{8.071 \text{ kmol}} = 0.4052$$

$$y_{\text{H}_2} = \frac{N_{\text{H}_2}}{N_m} = \frac{3.465 \text{ kmol}}{8.071 \text{ kmol}} = 0.4293$$

$$y_{\text{O}_2} = \frac{N_{\text{O}_2}}{N_m} = \frac{1.285 \text{ kmol}}{8.071 \text{ kmol}} = 0.1592$$

$$y_{\text{N}_2} = \frac{N_{\text{N}_2}}{N_m} = \frac{0.0257 \text{ kmol}}{8.071 \text{ kmol}} = 0.00319$$

$$y_{\text{S}} = \frac{N_{\text{S}}}{N_m} = \frac{0.0247 \text{ kmol}}{8.071 \text{ kmol}} = 0.00306$$

Ash consists of the non-combustible matter in coal. Therefore, the mass of ash content that enters the combustion chamber is equal to the mass content that leaves. Disregarding this non-reacting component for simplicity, the combustion equation may be written as

According to the O_2 mass balance,

$$0.1592 + 1.4a_{\text{th}} = 0.4052 + 0.5 \times 0.4293 + 0.4a_{\text{th}} + 0.00306 \longrightarrow a_{\text{th}} = 0.4637$$

Substituting,

The heat transfer for this combustion process is determined from the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $W = 0$. It reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{K}}$ kJ/kmol	$\bar{h}_{400\text{K}}$ kJ/kmol
O ₂	0	8682	11,711
N ₂	0	8669	11,640
H ₂ O (g)	-241,820	9904	13,356
CO ₂	-393,520	9364	13,372
SO ₂	-297,100	-	-

The enthalpy change of sulfur dioxide between the standard temperature and the product temperature using constant specific heat assumption is

$$\Delta \bar{h}_{\text{SO}_2} = c_p \Delta T = (41.7 \text{ kJ/kmol} \cdot \text{K})(127 - 25)\text{K} = 4253 \text{ kJ/kmol}$$

Substituting into the energy balance relation,

$$\begin{aligned} -\bar{Q}_{\text{out}} &= (0.4052)(-393,520 + 13,372 - 9364) + (0.4293)(-241,820 + 13,356 - 9904) \\ &\quad + (0.1855)(0 + 11,711 - 8682) + (2.441)(0 + 11,640 - 8669) + (0.00306)(-297,100 + 4253) - 0 \\ &= -253,244 \text{ kJ/kmol C}_8\text{H}_{18} \end{aligned}$$

or $\bar{Q}_{\text{out}} = 253,244 \text{ kJ/kmol fuel}$

Then the heat transfer per kg of fuel is

$$\begin{aligned} Q_{\text{out}} &= \frac{\bar{Q}_{\text{out}}}{M_{\text{fuel}}} = \frac{253,244 \text{ kJ/kmol fuel}}{(0.4052 \times 12 + 0.4293 \times 2 + 0.1592 \times 32 + 0.00319 \times 28 + 0.00306 \times 32) \text{ kg/kmol}} \\ &= \frac{253,244 \text{ kJ/kmol fuel}}{11.00 \text{ kg/kmol}} \\ &= \mathbf{23,020 \text{ kJ/kg coal}} \end{aligned}$$

15-59 Octane gas is burned with 30 percent excess air during a steady-flow combustion process. The heat transfer per unit mass of octane is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 Combustion is complete.

Properties The molar mass of C_8H_{18} is 114 kg/kmol (Table A-1).

Analysis The fuel is burned completely with the excess air, and thus the products will contain only CO_2 , H_2O , N_2 , and some free O_2 . The moisture in the air does not react with anything; it simply shows up as additional H_2O in the products.

Therefore, for simplicity, we will balance the combustion equation using dry air, and then add the moisture to both sides of the equation. Considering 1 kmol of C_8H_{18} , the combustion equation can be written as

where a_{th} is the stoichiometric coefficient for air. It is determined from

$$O_2 \text{ balance : } 1.8a_{th} = 8 + 4.5 + 0.8a_{th} \longrightarrow a_{th} = 12.5$$

Thus,

Therefore, $22.5 \times 4.76 = 107.1$ kmol of dry air will be used per kmol of the fuel. The partial pressure of the water vapor present in the incoming air is

$$P_{v,in} = \phi_{air} P_{sat@25^\circ C} = (0.40)(3.1698 \text{ kPa}) = 1.268 \text{ kPa}$$

Assuming ideal gas behavior, the number of moles of the moisture that accompanies 107.1 kmol of incoming dry air is determined to be

$$N_{v,in} = \left(\frac{P_{v,in}}{P_{total}} \right) N_{total} = \left(\frac{1.268 \text{ kPa}}{101.325 \text{ kPa}} \right) (107.1 + N_{v,in}) \longrightarrow N_{v,in} = 1.36 \text{ kmol}$$

The balanced combustion equation is obtained by adding 1.36 kmol of H_2O to both sides of the equation,

The heat transfer for this combustion process is determined from the energy balance $E_{in} - E_{out} = \Delta E_{system}$ applied on the combustion chamber with $W = 0$. It reduces to

$$-Q_{out} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R \bar{h}_{f,R}^\circ$$

since all of the reactants are at $25^\circ C$. Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° , kJ/kmol	\bar{h}_{298K} , kJ/kmol	\bar{h}_{1000K} , kJ/kmol
$C_8H_{18}(g)$	-208,450	---	---
O_2	0	8682	31,389
N_2	0	8669	30,129
$H_2O(g)$	-241,820	9904	35,882
CO_2	-393,520	9364	42,769

Substituting,

$$\begin{aligned} -Q_{out} &= (8)(-393,520 + 42,769 - 9364) + (10.36)(-241,820 + 35,882 - 9904) \\ &\quad + (10)(0 + 31,389 - 8682) + (84.6)(0 + 30,129 - 8669) \\ &\quad - (1)(-208,450) - (1.36)(-241,820) - 0 - 0 \\ &= -2,537,130 \text{ kJ/kmol } C_8H_{18} \end{aligned}$$

Thus 2,537,130 kJ of heat is transferred from the combustion chamber for each kmol (114 kg) of C_8H_{18} . Then the heat transfer per kg of C_8H_{18} becomes

$$q = \frac{Q_{out}}{M} = \frac{2,537,130 \text{ kJ}}{114 \text{ kg}} = \mathbf{22,260 \text{ kJ/kg } C_8H_{18}}$$

15-60 Problem 15-59 is reconsidered. The effect of the amount of excess air on the heat transfer for the combustion process is to be investigated.

Analysis The problem is solved using EES, and the solution is given below.

```

15-61 Diesel fuel is burned with 20 percent excess air during a steady-flow combustion process. The required mass flow rate of the diesel fuel to supply heat at a specified rate is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 Combustion is complete.

Analysis The fuel is burned completely with the excess air, and thus the products will contain only CO_2 , H_2O , N_2 , and some free O_2 . Considering 1 kmol of $\text{C}_{12}\text{H}_{26}$, the combustion equation can be written as

where a_{th} is the stoichiometric coefficient and is determined from the O_2 balance,

$$1.2a_{\text{th}} = 12 + 6.5 + 0.2a_{\text{th}} \longrightarrow a_{\text{th}} = 18.5$$

Substituting,

The heat transfer for this combustion process is determined from the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $W = 0$. It reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R \bar{h}_{f,R}^\circ$$

since all of the reactants are at 25°C . Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{ K}}$ kJ/kmol	$\bar{h}_{500\text{ K}}$ kJ/kmol
$\text{C}_{12}\text{H}_{26}$	-291,010	---	---
O_2	0	8682	14,770
N_2	0	8669	14,581
$\text{H}_2\text{O} (g)$	-241,820	9904	16,828
CO_2	-393,520	9364	17,678

Thus,

$$\begin{aligned} -Q_{\text{out}} &= (12)(-393,520 + 17,678 - 9364) + (13)(-241,820 + 16,828 - 9904) \\ &\quad + (3.7)(0 + 14,770 - 8682) + (83.47)(0 + 14,581 - 8669) - (1)(-291,010) - 0 - 0 \\ &= -6,869,110 \text{ kJ/kmol } \text{C}_{12}\text{H}_{26} \end{aligned}$$

or $\dot{Q}_{\text{out}} = 6,869,110 \text{ kJ/kmol } \text{C}_{12}\text{H}_{26}$

Then the required mass flow rate of fuel for a heat transfer rate of 2000 kJ/s becomes

$$\dot{m} = \dot{N}M = \left(\frac{\dot{Q}_{\text{out}}}{Q_{\text{out}}} \right) M = \left(\frac{2000 \text{ kJ/s}}{6,869,110 \text{ kJ/kmol}} \right) (170 \text{ kg/kmol}) = 0.0495 \text{ kg/s} = \mathbf{49.5 \text{ g/s}}$$

15-62 Liquid ethyl alcohol, C_2H_5OH (liq), is burned in a steady-flow combustion chamber with 40 percent excess air. The required volume flow rate of the liquid ethyl alcohol is to be determined.

Assumptions 1 Combustion is complete. **2** The combustion products contain CO_2 , H_2O , O_2 , and N_2 only.

Properties The molar masses of C, H_2 , O_2 and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis The reaction equation for 40% excess air is

where a_{th} is the stoichiometric coefficient for air. We have automatically accounted for the 40% excess air by using the factor $1.4a_{th}$ instead of a_{th} for air. The coefficient a_{th} and other coefficients are to be determined from the mass balances

$$\text{Carbon balance:} \quad B = 2$$

$$\text{Hydrogen balance:} \quad 2D = 6 \longrightarrow D = 3$$

$$\text{Oxygen balance:} \quad 1 + 2 \times 1.4a_{th} = 2B + D + 2E$$

$$0.4a_{th} = E$$

$$\text{Nitrogen balance:} \quad 1.4a_{th} \times 3.76 = F$$

Solving the above equations, we find the coefficients ($E = 1.2$, $F = 15.79$, and $a_{th} = 3$) and write the balanced reaction equation as

The steady-flow energy balance is expressed as

$$\dot{N}_{fuel} H_R = \dot{Q}_{out} + \dot{N}_{fuel} H_P$$

where

$$\begin{aligned} H_R &= (\bar{h}_f^\circ - \bar{h}_{fg})_{fuel} + 4.2\bar{h}_{O_2@298.15K} + (4.2 \times 3.76)\bar{h}_{N_2@298.15K} \\ &= -235,310 \text{ kJ/kmol} - 42,340 \text{ kJ/kmol} + 4.2(-4.425 \text{ kJ/kmol}) + (4.2 \times 3.76)(-4.376 \text{ kJ/kmol}) \\ &= -277,650 \text{ kJ/kmol} \end{aligned}$$

$$\begin{aligned} H_P &= 2\bar{h}_{CO_2@600K} + 3\bar{h}_{H_2O@600K} + 1.2\bar{h}_{O_2@600K} + 15.79\bar{h}_{N_2@600K} \\ &= 2(-380,623 \text{ kJ/kmol}) + 3(-231,333 \text{ kJ/kmol}) + 1.2(9251 \text{ kJ/kmol}) + 15.79(8889 \text{ kJ/kmol}) \\ &= -1.304 \times 10^6 \text{ kJ/kmol} \end{aligned}$$

The enthalpies are obtained from EES except for the enthalpy of formation of the fuel, which is obtained in Table A-27 of the book. Substituting into the energy balance equation,

$$\begin{aligned} \dot{N}_{fuel} H_R &= \dot{Q}_{out} + \dot{N}_{fuel} H_P \\ \dot{N}_{fuel} (-277,650 \text{ kJ/kmol}) &= 2000 \text{ kJ/s} + \dot{N}_{fuel} (-1.304 \times 10^6 \text{ kJ/kmol}) \longrightarrow \dot{N}_{fuel} = 0.001949 \text{ kmol/s} \end{aligned}$$

The fuel mass flow rate is

$$\dot{m}_{fuel} = \dot{N}_{fuel} M_{fuel} = (0.001949 \text{ kmol/s})(2 \times 12 + 6 \times 1 + 16) \text{ kg/kmol} = 0.08966 \text{ kg/s}$$

Then, the volume flow rate of the fuel is determined to be

$$\dot{V}_{fuel} = \frac{\dot{m}_{fuel}}{\rho_{fuel}} = \frac{0.08966 \text{ kg/s}}{790 \text{ kg/m}^3} \left(\frac{6000 \text{ L/min}}{1 \text{ m}^3/\text{s}} \right) = \mathbf{6.81 \text{ L/min}}$$

15-63 A mixture of propane and methane is burned with theoretical air. The balanced chemical reaction is to be written, and the amount of water vapor condensed and the the required air flow rate for a given heat transfer rate are to be determined.

Assumptions 1 Combustion is complete. 2 The combustion products contain CO_2 , CO , H_2O , O_2 , and N_2 only.

Properties The molar masses of C, H_2 , O_2 , N_2 and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, 28 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis (a) The balanced reaction equation for stoichiometric air is

The stoichiometric coefficient a_{th} is determined from an O_2 balance:

$$a_{\text{th}} = 1.8 + 1.4 = 3.2$$

Substituting,

(b) The partial pressure of water vapor is

$$P_v = \frac{N_{\text{H}_2\text{O}}}{N_{\text{total}}} P_{\text{total}} = \frac{2.8}{1.8 + 2.8 + 12.032} (100 \text{ kPa}) = \frac{2.8 \text{ kmol}}{16.632 \text{ kmol}} (100 \text{ kPa}) = 16.84 \text{ kPa}$$

The dew point temperature of the product gases is the saturation temperature of water at this pressure:

$$T_{dp} = T_{\text{sat}@16.84\text{kPa}} = 56.2^\circ\text{C} \quad (\text{Table A-5})$$

Since the temperature of the product gases are at 423 K (150°C), there will be no condensation of water vapor.

(c) The heat transfer for this combustion process is determined from the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $W = 0$. It reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

The products are at 125°C , and the enthalpy of products can be expressed as

$$(\bar{h} - \bar{h}^\circ) = \bar{c}_p \Delta T$$

where $\Delta T = 150 - 25 = 125^\circ\text{C} = 125 \text{ K}$. Then, using the values given in the table,

$$\begin{aligned} -Q_{\text{out}} &= (1.8)(-393,520 + 41.16 \times 125) + (2.8)(-241,820 + 34.28 \times 125) + (12.032)(0 + 29.27 \times 125) \\ &\quad - (0.4)(-103,850) - (0.6)(-74,850) \\ &= -1,233,700 \text{ kJ/kmol fuel} \end{aligned}$$

or $Q_{\text{out}} = 1,233,700 \text{ kJ/kmol fuel}$

For a heat transfer rate of 140,000 kJ/h, the molar flow rate of fuel is

$$\dot{N}_{\text{fuel}} = \frac{\dot{Q}_{\text{out}}}{Q_{\text{out}}} = \frac{140,000 \text{ kJ/h}}{1,246,760 \text{ kJ/kmol fuel}} = 0.1135 \text{ kmol fuel/h}$$

The molar mass of the fuel mixture is

$$M_{\text{fuel}} = 0.4 \times 44 + 0.6 \times 16 = 27.2 \text{ kg/kmol}$$

The mass flow rate of fuel is

$$\dot{m}_{\text{fuel}} = \dot{N}_{\text{fuel}} M_{\text{fuel}} = (0.1135 \text{ kmol/h})(27.2 \text{ kg/kmol}) = 3.087 \text{ kg/h}$$

The air-fuel ratio is

$$\text{AF} = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{(3.2 \times 4.76 \times 29) \text{ kg}}{(0.4 \times 44 + 0.6 \times 16) \text{ kg}} = 16.24 \text{ kg air/kg fuel}$$

The mass flow rate of air is then

$$\dot{m}_{\text{air}} = \dot{m}_{\text{fuel}} \text{AF} = (3.087 \text{ kg/h})(16.24) = \mathbf{50.1 \text{ kg/h}}$$

15-64 A mixture of ethanol and octane is burned with 10% excess air. The combustion is incomplete. The balanced chemical reaction is to be written, and the dew-point temperature of the products, the heat transfer for the process, and the relative humidity of atmospheric air for specified conditions are to be determined.

Assumptions 1 Combustion is incomplete. **2** The combustion products contain CO_2 , CO , H_2O , O_2 , and N_2 only.

Properties The molar masses of C, H_2 , O_2 , N_2 and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, 28 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis (a) The balanced reaction equation for stoichiometric air is

The stoichiometric coefficient a_{th} is determined from an O_2 balance:

$$0.1/2 + a_{\text{th}} = 7.4 + 8.4/2 \longrightarrow a_{\text{th}} = 11.55$$

Substituting,

The reaction with 10% excess air and incomplete combustion can be written as

The coefficient for O_2 is determined from a mass balance,

$$\text{O}_2 \text{ balance: } 0.5 \times 0.1 + 1.1 \times 11.55 = 0.9 \times 7.4 + 0.5 \times (0.1 \times 7.4) + 0.5 \times 8.4 + x \longrightarrow x = 1.525$$

Substituting,

(b) The partial pressure of water vapor is

$$P_v = \frac{N_{\text{H}_2\text{O}}}{N_{\text{total}}} P_{\text{total}} = \frac{8.4}{6.66 + 0.74 + 8.4 + 1.525 + 47.77} (100 \text{ kPa}) = \frac{8.4 \text{ kmol}}{65.10 \text{ kmol}} (100 \text{ kPa}) = 12.9 \text{ kPa}$$

The dew point temperature of the product gases is the saturation temperature of water at this pressure:

$$T_{dp} = T_{\text{sat}@12.9\text{kPa}} = \mathbf{50.5^\circ\text{C}} \quad (\text{Table A-5})$$

(c) The heat transfer for this combustion process is determined from the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $W = 0$. It reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Both the reactants and products are at 25°C . Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. Then, using the values given in the table,

$$\begin{aligned} -Q_{\text{out}} &= (6.66)(-393,520) + (0.74)(-110,530) + (8.4)(-241,820) - (0.1)(-235,310) - (0.9)(-208,450) \\ &= -4,522,790 \text{ kJ/kmol fuel} \end{aligned}$$

or $Q_{\text{out}} = 4,522,790 \text{ kJ/kmol fuel}$

The molar mass of the fuel is

$$M = 0.1 \times 46 + 0.9 \times 114 = 107.2 \text{ kg/kmol}$$

Then the heat transfer for a 2.5 kg of fuel becomes

$$Q_{\text{out}} = NQ_{\text{out}} = \left(\frac{m}{M} \right) Q_{\text{out}} = \frac{2.5 \text{ kg}}{107.2 \text{ kg/kmol}} (4,522,790 \text{ kJ/mol}) = \mathbf{105,480 \text{ kJ}}$$

(d) For 9.57 kmol of water vapor in the products, the air must carry $9.57 - 8.4 = 1.17$ kmol of water vapor in the atmospheric air. The partial pressure of this water vapor in the atmospheric air is

$$P_v = \frac{N_{\text{H}_2\text{O}}}{N_{\text{total}}} P_{\text{total}} = \frac{1.17}{12.705 \times 4.76 + 1.17} (100 \text{ kPa}) = \frac{1.17 \text{ kmol}}{61.65 \text{ kmol}} (100 \text{ kPa}) = 1.8979 \text{ kPa}$$

The saturation pressure of water at 25°C is 3.17 kPa (Table A-4). The relative humidity of water vapor in the atmospheric air is then

$$\phi = \frac{P_v}{P_{\text{total}}} = \frac{1.8979 \text{ kPa}}{3.17 \text{ kPa}} = 0.599 = \mathbf{59.9\%}$$

15-65  A mixture of methane and oxygen contained in a tank is burned at constant volume. The final pressure in the tank and the heat transfer during this process are to be determined.

Assumptions **1** Air and combustion gases are ideal gases. **2** Combustion is complete.

Properties The molar masses of CH_4 and O_2 are 16 kg/kmol and 32 kg/kmol, respectively (Table A-1).

Analysis (a) The combustion is assumed to be complete, and thus all the carbon in the methane burns to CO_2 and all of the hydrogen to H_2O . The number of moles of CH_4 and O_2 in the tank are

$$N_{\text{CH}_4} = \frac{m_{\text{CH}_4}}{M_{\text{CH}_4}} = \frac{0.12 \text{ kg}}{16 \text{ kg/kmol}} = 7.5 \times 10^{-3} \text{ kmol} = 7.5 \text{ mol}$$

$$N_{\text{O}_2} = \frac{m_{\text{O}_2}}{M_{\text{O}_2}} = \frac{0.6 \text{ kg}}{32 \text{ kg/kmol}} = 18.75 \times 10^{-3} \text{ kmol} = 18.75 \text{ mol}$$

Then the combustion equation can be written as

At 1200 K, water exists in the gas phase. Assuming both the reactants and the products to be ideal gases, the final pressure in the tank is determined to be

$$\left. \begin{array}{l} P_R \mathcal{V} = N_R R_u T_R \\ P_P \mathcal{V} = N_P R_u T_P \end{array} \right\} P_P = P_R \left(\frac{N_P}{N_R} \right) \left(\frac{T_P}{T_R} \right)$$

Substituting,

$$P_P = (200 \text{ kPa}) \left(\frac{26.25 \text{ mol}}{26.25 \text{ mol}} \right) \left(\frac{1200 \text{ K}}{298 \text{ K}} \right) = \mathbf{805 \text{ kPa}}$$

which is relatively low. Therefore, the ideal gas assumption utilized earlier is appropriate.

(b) The heat transfer for this constant volume combustion process is determined from the energy balance

$E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $W = 0$. It reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_R$$

Since both the reactants and products are assumed to be ideal gases, all the internal energy and enthalpies depend on temperature only, and the $P\bar{v}$ terms in this equation can be replaced by $R_u T$. It yields

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h}_{1200 \text{ K}} - \bar{h}_{298 \text{ K}} - R_u T)_P - \sum N_R (\bar{h}_f^\circ - R_u T)_R$$

since the reactants are at the standard reference temperature of 25°C. From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298 \text{ K}}$ kJ/kmol	$\bar{h}_{1200 \text{ K}}$ kJ/kmol
CH_4	-74,850	---	---
O_2	0	8682	38,447
$\text{H}_2\text{O} (g)$	-241,820	9904	44,380
CO_2	-393,520	9364	53,848

Thus,

$$\begin{aligned} -Q_{\text{out}} &= (7.5)(-393,520 + 53,848 - 9364 - 8.314 \times 1200) \\ &\quad + (15)(-241,820 + 44,380 - 9904 - 8.314 \times 1200) \\ &\quad + (3.75)(0 + 38,447 - 8682 - 8.314 \times 1200) \\ &\quad - (7.5)(-74,850 - 8.314 \times 298) - (18.75)(-8.314 \times 298) \\ &= -5,251,791 \text{ J} = \mathbf{-5252 \text{ kJ}} \end{aligned}$$

Thus $Q_{\text{out}} = \mathbf{5252 \text{ kJ}}$ of heat is transferred from the combustion chamber as 120 g of CH_4 burned in this combustion chamber.

15-66 Problem 15-65 is reconsidered. The effect of the final temperature on the final pressure and the heat transfer for the combustion process is to be investigated.

Analysis The problem is solved using EES, and the solution is given below.

1300	5151	872.5
1500	4943	1007

15-67E Methane is burned with stoichiometric amount of air in a rigid container. The heat rejected from the container is to be determined.

Assumptions 1 Air and combustion gases are ideal gases. **2** Combustion is complete.

Properties The molar masses of CH₄ and air are 16 lbm/lbmol and 29 lbm/lbmol, respectively (Table A-1E).

Analysis The combustion equation for 1 lbmol of fuel is

The heat transfer for this constant volume combustion process is determined from the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $W = 0$. It reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_R$$

Since both the reactants and products are assumed to be ideal gases, all the internal energy and enthalpies depend on temperature only, and the $P\bar{v}$ terms in this equation can be replaced by $R_u T$. It yields

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h}_{1520R} - \bar{h}_{537R} - R_u T)_P - \sum N_R (\bar{h}_f^\circ - R_u T)_R$$

since the reactants are at the standard reference temperature of 77°F. From the tables,

Substance	\bar{h}_f° Btu/lbmol	\bar{h}_{537R} Btu/lbmol	\bar{h}_{1260R} Btu/lbmol
CH ₄	-32,210	---	---
O ₂	0	3725.1	9096.7
N ₂	0	3729.5	8859.3
H ₂ O (g)	-104,040	4258.0	10,354.9
CO ₂	-169,300	4027.5	11,661.0

Thus,

$$\begin{aligned} -Q_{\text{out}} &= (1)(-169,300 + 11,661.0 - 4027.5 - 1.9858 \times 1260) \\ &\quad + (2)(-104,040 + 10,354.9 - 4258.0 - 1.9858 \times 1260) \\ &\quad + (7.52)(0 + 8859.3 - 3729.5 - 1.9858 \times 1260) \\ &\quad - (1)(-32,210 - 1.9858 \times 537) - (2)(-1.9858 \times 537) - (7.52)(-1.9858 \times 537) \\ &= -301,900 \text{ Btu/lbmol CH}_4 \end{aligned}$$

Thus

$$Q_{\text{out}} = \mathbf{301,900 \text{ Btu/lbmol CH}_4}$$

15-68 A stoichiometric mixture of octane gas and air contained in a closed combustion chamber is ignited. The heat transfer from the combustion chamber is to be determined.

Assumptions 1 Both the reactants and products are ideal gases. **2** Combustion is complete.

Analysis The theoretical combustion equation of C_8H_{18} with stoichiometric amount of air is

where a_{th} is the stoichiometric coefficient and is determined from the O_2 balance,

$$a_{th} = 8 + 4.5 = 12.5$$

Thus,

The heat transfer for this constant volume combustion process is determined from the energy balance $E_{in} - E_{out} = \Delta E_{system}$ applied on the combustion chamber with $W_{other} = 0$,

$$-Q_{out} = \sum N_P(\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_P - \sum N_R(\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_R$$

For a constant pressure quasi-equilibrium process $\Delta U + W_b = \Delta H$. Then the first law relation in this case is

$$-Q_{out} = \sum N_P(\bar{h}_f^\circ + \bar{h}_{1000K} - \bar{h}_{298K})_P - \sum N_R\bar{h}_{f,R}^\circ$$

since the reactants are at the standard reference temperature of 25°C . Since both the reactants and the products behave as ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{ K}}$ kJ/kmol	$\bar{h}_{1000\text{ K}}$ kJ/kmol
$C_8H_{18}(g)$	-208,450	---	---
O_2	0	8682	31,389
N_2	0	8669	30,129
$H_2O(g)$	-241,820	9904	35,882
CO_2	-393,520	9364	42,769

Thus,

$$\begin{aligned} -Q_{out} &= (8)(-393,520 + 42,769 - 9364) + (9)(-241,820 + 35,882 - 9904) \\ &\quad + (47)(0 + 30,129 - 8669) - (1)(-208,450) - 0 - 0 \\ &= -3,606,428 \text{ kJ (per kmol of } C_8H_{18}) \end{aligned}$$

or $Q_{out} = 3,606,428 \text{ kJ (per kmol of } C_8H_{18})$.

Total mole numbers initially present in the combustion chamber is determined from the ideal gas relation,

$$N_1 = \frac{P_1 V_1}{R_u T_1} = \frac{(300 \text{ kPa})(0.5 \text{ m}^3)}{(8.314 \text{ kPa} \cdot \text{m}^3/\text{kmol} \cdot \text{K})(298 \text{ K})} = 0.06054 \text{ kmol}$$

Of these, $0.06054 / (1 + 12.5 \times 4.76) = 1.001 \times 10^{-3}$ kmol of them is C_8H_{18} . Thus the amount of heat transferred from the combustion chamber as 1.001×10^{-3} kmol of C_8H_{18} is burned is

$$Q_{out} = (1.001 \times 10^{-3} \text{ kmol } C_8H_{18})(3,606,428 \text{ kJ/kmol } C_8H_{18}) = \mathbf{3610 \text{ kJ}}$$

15-69 A high efficiency gas furnace burns gaseous propane C_3H_8 with 140 percent theoretical air. The volume flow rate of water condensed from the product gases is to be determined.

Assumptions 1 Combustion is complete. **2** The combustion products contain CO_2 , H_2O , O_2 , and N_2 only.

Properties The molar masses of C, H_2 , O_2 and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis The reaction equation for 40% excess air (140% theoretical air) is

where a_{th} is the stoichiometric coefficient for air. We have automatically accounted for the 40% excess air by using the factor $1.4a_{th}$ instead of a_{th} for air. The coefficient a_{th} and other coefficients are to be determined from the mass balances

$$\text{Carbon balance:} \quad B = 3$$

$$\text{Hydrogen balance:} \quad 2D = 8 \longrightarrow D = 4$$

$$\text{Oxygen balance:} \quad 2 \times 1.4a_{th} = 2B + D + 2E$$

$$0.4a_{th} = E$$

$$\text{Nitrogen balance:} \quad 1.4a_{th} \times 3.76 = F$$

Solving the above equations, we find the coefficients ($E = 2$, $F = 26.32$, and $a_{th} = 5$) and write the balanced reaction equation as

The partial pressure of water in the saturated product mixture at the dew point is

$$P_{v,prod} = P_{sat@40^\circ C} = 7.3851 \text{ kPa}$$

The vapor mole fraction is

$$y_v = \frac{P_{v,prod}}{P_{prod}} = \frac{7.3851 \text{ kPa}}{100 \text{ kPa}} = 0.07385$$

The kmoles of water condensed is determined from

$$y_v = \frac{N_{water}}{N_{total,product}} \longrightarrow 0.07385 = \frac{4 - N_w}{3 + 4 - N_w + 2 + 26.32} \longrightarrow N_w = 1.503 \text{ kmol}$$

The steady-flow energy balance is expressed as

$$\dot{N}_{fuel} H_R = \dot{Q}_{fuel} + \dot{N}_{fuel} H_P$$

where $\dot{Q}_{fuel} = \frac{\dot{Q}_{out}}{\eta_{furnace}} = \frac{31,650 \text{ kJ/h}}{0.96} = 32,969 \text{ kJ/h}$

$$H_R = \bar{h}_{f, fuel@25^\circ C}^o + 7\bar{h}_{O_2@25^\circ C} + 26.32\bar{h}_{N_2@25^\circ C}$$

$$= (-103,847 \text{ kJ/kmol}) + 7(0) + 26.32(0) = -103,847 \text{ kJ/kmol}$$

$$H_P = 3\bar{h}_{CO_2@25^\circ C} + 4\bar{h}_{H_2O@25^\circ C} + 2\bar{h}_{O_2@25^\circ C} + 26.32\bar{h}_{N_2@25^\circ C} + N_w(\bar{h}_{H_2O(liq)}^o)$$

$$= 3(-393,520 \text{ kJ/kmol}) + 4(-241,820 \text{ kJ/kmol}) + 2(0) + 26.32(0) + 1.503(-285,830 \text{ kJ/kmol})$$

$$= -2.577 \times 10^6 \text{ kJ/kmol}$$

Substituting into the energy balance equation,

$$\dot{N}_{fuel} H_R = \dot{Q}_{fuel} + \dot{N}_{fuel} H_P$$

$$\dot{N}_{fuel}(-103,847 \text{ kJ/kmol}) = 32,969 \text{ kJ/h} + \dot{N}_{fuel}(-2.577 \times 10^6 \text{ kJ/kmol}) \longrightarrow \dot{N}_{fuel} = 0.01333 \text{ kmol/h}$$

The molar and mass flow rates of the liquid water are

$$\dot{N}_w = N_w \dot{N}_{fuel} = (1.503 \text{ kmol/kmol fuel})(0.01333 \text{ kmol fuel/h}) = 0.02003 \text{ kmol/h}$$

$$\dot{m}_w = \dot{N}_w M_w = (0.02003 \text{ kmol/h})(18 \text{ kg/kmol}) = 0.3608 \text{ kg/h}$$

The volume flow rate of liquid water is

$$\dot{V}_w = (v_{f@25^\circ C}) \dot{m}_w = (0.001003 \text{ m}^3/\text{kg})(0.3608 \text{ kg/h}) = 0.0003619 \text{ m}^3/\text{h} = \mathbf{8.7 \text{ L/day}}$$

Adiabatic Flame Temperature

15-70C For the case of stoichiometric amount of pure oxygen since we have the same amount of chemical energy released but a smaller amount of mass to absorb it.

15-71C Under the conditions of complete combustion with stoichiometric amount of air.

15-72 Acetylene is burned with stoichiometric amount of oxygen. The adiabatic flame temperature is to be determined.

Assumptions 1 Steady operating conditions exist. **2** Air and combustion gases are ideal gases. **3** Kinetic and potential energies are negligible. **4** There are no work interactions. **5** The combustion chamber is adiabatic.

Analysis Under steady-flow conditions the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $Q = W = 0$ reduces to

$$\sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P = \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R \longrightarrow \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P = \sum N_R \bar{h}_{f,R}^\circ$$

since all the reactants are at the standard reference temperature of 25°C. Then, for the stoichiometric oxygen

From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{K}}$ kJ/kmol
C ₂ H ₂ (g)	226,730	---
O ₂	0	8682
N ₂	0	8669
H ₂ O (g)	-241,820	9904
CO ₂	-393,520	9364

Thus,

$$(2)(-393,520 + \bar{h}_{\text{CO}_2} - 9364) + (1)(-241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904) = (1)(226,730) + 0 + 0$$

It yields $2\bar{h}_{\text{CO}_2} + \bar{h}_{\text{H}_2\text{O}} = 1,284,220 \text{ kJ}$

The adiabatic flame temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields $2,284,220/(2+1) = 428,074 \text{ kJ/kmol}$. The ideal gas tables do not list enthalpy values this high. Therefore, we cannot use the tables to estimate the adiabatic flame temperature. In Table A-2b, the highest available value of specific heat is $c_p = 1.234 \text{ kJ/kg}\cdot\text{K}$ for CO₂ at 1000 K. The specific heat of water vapor is $c_p = 1.8723 \text{ kJ/kg}\cdot\text{K}$ (Table A-2a). Using these specific heat values,

$$(2)(-393,520 + \bar{c}_p \Delta T) + (1)(-241,820 + \bar{c}_p \Delta T) = (1)(226,730) + 0 + 0$$

where $\Delta T = (T_{\text{af}} - 25)^\circ\text{C}$. The specific heats on a molar base are

$$\bar{c}_{p,\text{CO}_2} = \bar{c}_p M = (1.234 \text{ kJ/kg}\cdot\text{K})(44 \text{ kg/kmol}) = 54.3 \text{ kJ/kmol}\cdot\text{K}$$

$$\bar{c}_{p,\text{H}_2\text{O}} = \bar{c}_p M = (1.8723 \text{ kJ/kg}\cdot\text{K})(18 \text{ kg/kmol}) = 33.7 \text{ kJ/kmol}\cdot\text{K}$$

Substituting,

$$(2)(-393,520 + 54.3\Delta T) + (1)(-241,820 + 33.7\Delta T) = 226,730$$

$$(2 \times 54.3)\Delta T + 33.7\Delta T = 1,255,590$$

$$\Delta T = \frac{1,255,590 \text{ kJ/kmol}}{(2 \times 54.3 + 33.7) \text{ kJ/kmol}\cdot\text{K}} = 8824 \text{ K}$$

Then the adiabatic flame temperature is estimated as

$$T_{\text{af}} = \Delta T + 25 = 8824 + 25 = \mathbf{8849^\circ\text{C}}$$

15-73 Propane is burned with stoichiometric and 50 percent excess air. The adiabatic flame temperature is to be determined for both cases.

Assumptions 1 Steady operating conditions exist. **2** Air and combustion gases are ideal gases. **3** Kinetic and potential energies are negligible. **4** There are no work interactions. **5** The combustion chamber is adiabatic.

Analysis Under steady-flow conditions the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $Q = W = 0$ reduces to

$$\sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P = \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R \longrightarrow \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P = \sum N_R \bar{h}_{f,R}^\circ$$

since all the reactants are at the standard reference temperature of 25°C. Then, for the stoichiometric air

where a_{th} is the stoichiometric coefficient and is determined from the O_2 balance,

$$a_{\text{th}} = 3 + 2 = 5$$

Thus,

From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{K}}$ kJ/kmol
$\text{C}_3\text{H}_8(g)$	-103,850	---
O_2	0	8682
N_2	0	8669
$\text{H}_2\text{O}(g)$	-241,820	9904
CO_2	-393,520	9364

Thus,

$$(3)(-393,520 + \bar{h}_{\text{CO}_2} - 9364) + (4)(-241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904) + (18.8)(0 + \bar{h}_{\text{N}_2} - 8669) = (1)(-103,850) + 0 + 0$$

It yields $3\bar{h}_{\text{CO}_2} + 4\bar{h}_{\text{H}_2\text{O}} + 18.8\bar{h}_{\text{N}_2} = 2,274,680 \text{ kJ}$

The adiabatic flame temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields $2,274,680/(3 + 4 + 18.8) = 88,166 \text{ kJ/kmol}$. This enthalpy value corresponds to about 2650 K for N_2 . Noting that the majority of the moles are N_2 , T_P will be close to 2650 K, but somewhat under it because of the higher specific heat of H_2O .

At 2500 K:

$$\begin{aligned} 3\bar{h}_{\text{CO}_2} + 4\bar{h}_{\text{H}_2\text{O}} + 18.8\bar{h}_{\text{N}_2} &= 3 \times 131,290 + 4 \times 108,868 + 18.8 \times 82,981 \\ &= 2,389,380 \text{ kJ (Higher than 2,274,680 kJ)} \end{aligned}$$

At 2450 K:

$$\begin{aligned} 3\bar{h}_{\text{CO}_2} + 4\bar{h}_{\text{H}_2\text{O}} + 18.8\bar{h}_{\text{N}_2} &= 3 \times 128,219 + 4 \times 106,183 + 18.8 \times 81,149 \\ &= 2,334,990 \text{ kJ (Higher than 2,274,680 kJ)} \end{aligned}$$

At 2400 K:

$$\begin{aligned} 3\bar{h}_{\text{CO}_2} + 4\bar{h}_{\text{H}_2\text{O}} + 18.8\bar{h}_{\text{N}_2} &= 3 \times 125,152 + 4 \times 103,508 + 18.8 \times 79,320 \\ &= 2,280,704 \text{ kJ (Higher than 2,274,680 kJ)} \end{aligned}$$

At 2350 K:

$$3\bar{h}_{\text{CO}_2} + 4\bar{h}_{\text{H}_2\text{O}} + 18.8\bar{h}_{\text{N}_2} = 3 \times 122,091 + 4 \times 100,846 + 18.8 \times 77,496 \\ = 2,226,580 \text{ kJ (Lower than 2,274,680 kJ)}$$

By interpolation of the two results,

$$T_p = \mathbf{2394 \text{ K} = 2121^\circ\text{C}}$$

When propane is burned with 20% excess air, the reaction equation may be written as

where a_{th} is the stoichiometric coefficient and is determined from the O_2 balance,

$$1.2a_{\text{th}} = 3 + 2 + 0.2a_{\text{th}} \longrightarrow a_{\text{th}} = 5$$

Thus,

Using the values in the table,

$$(3)(-393,520 + \bar{h}_{\text{CO}_2} - 9364) + (4)(-241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904) + (1)(0 + \bar{h}_{\text{O}_2} - 8682) \\ + (22.56)(0 + \bar{h}_{\text{N}_2} - 8669) = (1)(-103,850) + 0 + 0$$

It yields

$$3\bar{h}_{\text{CO}_2} + 4\bar{h}_{\text{H}_2\text{O}} + 1\bar{h}_{\text{O}_2} + 22.56\bar{h}_{\text{N}_2} = 2,315,950 \text{ kJ}$$

The adiabatic flame temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields $2,315,950/(3+4+1+22.56) = 75,784 \text{ kJ/kmol}$. This enthalpy value corresponds to about 2300 K for N_2 . Noting that the majority of the moles are N_2 , T_p will be close to 2300 K, but somewhat under it because of the higher specific heat of H_2O .

At 2100 K:

$$3\bar{h}_{\text{CO}_2} + 4\bar{h}_{\text{H}_2\text{O}} + 1\bar{h}_{\text{O}_2} + 22.56\bar{h}_{\text{N}_2} = 3 \times 106,864 + 4 \times 87,735 + 1 \times 71,668 + 22.56 \times 68,417 \\ = 2,286,690 \text{ kJ (Lower than 2,315,950 kJ)}$$

At 2150 K:

$$3\bar{h}_{\text{CO}_2} + 4\bar{h}_{\text{H}_2\text{O}} + 1\bar{h}_{\text{O}_2} + 22.56\bar{h}_{\text{N}_2} = 3 \times 109,898 + 4 \times 90,330 + 1 \times 73,573 + 22.56 \times 70,226 \\ = 2,348,890 \text{ kJ (Higher than 2,315,950 kJ)}$$

By interpolation,

$$T_p = 2124 \text{ K} = \mathbf{1851^\circ\text{C}}$$

15-74 Acetylene gas is burned with 30 percent excess air during a steady-flow combustion process. The exit temperature of product gases is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 There are no work interactions.

Analysis The fuel is burned completely with the excess air, and thus the products will contain only CO_2 , H_2O , N_2 , and some free O_2 . Considering 1 kmol of C_2H_2 , the combustion equation can be written as

where a_{th} is the stoichiometric coefficient and is determined from the O_2 balance,

$$1.3a_{\text{th}} = 2 + 0.5 + 0.3a_{\text{th}} \longrightarrow a_{\text{th}} = 2.5$$

Thus,

Under steady-flow conditions the energy balance

$E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with

$W = 0$ reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{ K}}$ kJ/kmol	$\bar{h}_{300\text{ K}}$ kJ/kmol
C_2H_2	226,730	---	---
O_2	0	8682	8736
N_2	0	8669	8723
$\text{H}_2\text{O} (g)$	-241,820	9904	---
CO_2	-393,520	9364	---

Thus,

$$\begin{aligned} -75,000 &= (2)(-393,520 + \bar{h}_{\text{CO}_2} - 9364) + (1)(-241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904) \\ &+ (0.75)(0 + \bar{h}_{\text{O}_2} - 8682) + (12.22)(0 + \bar{h}_{\text{N}_2} - 8669) - (1)(226,730) \\ &- (3.25)(0 + 8736 - 8682) + (12.22)(0 + 8723 - 8669) \end{aligned}$$

It yields

$$2\bar{h}_{\text{CO}_2} + \bar{h}_{\text{H}_2\text{O}} + 0.75\bar{h}_{\text{O}_2} + 12.22\bar{h}_{\text{N}_2} = 1,321,184 \text{ kJ}$$

The temperature of the product gases is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields $1,321,184 / (2 + 1 + 0.75 + 12.22) = 82,729$ kJ/kmol. This enthalpy value corresponds to about 2500 K for N_2 . Noting that the majority of the moles are N_2 , T_P will be close to 2500 K, but somewhat under it because of the higher specific heats of CO_2 and H_2O .

At 2350 K:

$$\begin{aligned} 2\bar{h}_{\text{CO}_2} + \bar{h}_{\text{H}_2\text{O}} + 0.75\bar{h}_{\text{O}_2} + 12.22\bar{h}_{\text{N}_2} &= (2)(122,091) + (1)(100,846) + (0.75)(81,243) + (12.22)(77,496) \\ &= 1,352,961 \text{ kJ (Higher than 1,321,184 kJ)} \end{aligned}$$

At 2300 K:

$$\begin{aligned} 2\bar{h}_{\text{CO}_2} + \bar{h}_{\text{H}_2\text{O}} + 0.75\bar{h}_{\text{O}_2} + 12.22\bar{h}_{\text{N}_2} &= (2)(119,035) + (1)(98,199) + (0.75)(79,316) + (12.22)(75,676) \\ &= 1,320,517 \text{ kJ (Lower than 1,321,184 kJ)} \end{aligned}$$

By interpolation,

$$T_P = \mathbf{2301 \text{ K}}$$

15-75 Octane gas is burned with 30 percent excess air during a steady-flow combustion process. The exit temperature of product gases is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 There are no work interactions. 5 The combustion chamber is adiabatic.

Analysis Under steady-flow conditions the energy balance $E_{in} - E_{out} = \Delta E_{system}$ applied on the combustion chamber with $Q = W = 0$ reduces to

$$\sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P = \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R \longrightarrow \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P = \sum N_R \bar{h}_{f,R}^\circ$$

since all the reactants are at the standard reference temperature of 25°C. Then,

where a_{th} is the stoichiometric coefficient and is determined from the O_2 balance,

$$1.3a_{\text{th}} = 8 + 4.5 + 0.3a_{\text{th}} \longrightarrow a_{\text{th}} = 12.5$$

Therefore, $16.25 \times 4.76 = 77.35$ kmol of dry air will be used per kmol of the fuel. The partial pressure of the water vapor present in the incoming air is

$$P_{v,\text{in}} = \phi_{\text{air}} P_{\text{sat}@25^\circ\text{C}} = (0.60)(3.1698 \text{ kPa}) = 1.902 \text{ kPa}$$

Assuming ideal gas behavior, the number of moles of the moisture that accompanies 77.35 kmol of incoming dry air is determined to be

$$N_{v,\text{in}} = \left(\frac{P_{v,\text{in}}}{P_{\text{total}}} \right) N_{\text{total}} = \left(\frac{1.902 \text{ kPa}}{101.325 \text{ kPa}} \right) (77.35 + N_{v,\text{in}}) \longrightarrow N_{v,\text{in}} = 1.48 \text{ kmol}$$

The balanced combustion equation is obtained by adding 1.48 kmol of H_2O to both sides of the equation,

From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298 \text{ K}}$ kJ/kmol
$\text{C}_8\text{H}_{18}(\text{g})$	-208,450	---
O_2	0	8682
N_2	0	8669
$\text{H}_2\text{O}(\text{g})$	-241,820	9904
CO_2	-393,520	9364

Thus,

$$(8)(-393,520 + \bar{h}_{\text{CO}_2}) + (10.48)(-241,820 + \bar{h}_{\text{H}_2\text{O}}) + (3.75)(0 + \bar{h}_{\text{O}_2} - 8682) + (61.1)(0 + \bar{h}_{\text{N}_2} - 8669) = (1)(-208,450) + (1.48)(-241,820) + 0 + 0$$

$$\text{It yields } 8\bar{h}_{\text{CO}_2} + 10.48\bar{h}_{\text{H}_2\text{O}} + 3.75\bar{h}_{\text{O}_2} + 61.1\bar{h}_{\text{N}_2} = 5,857,029 \text{ kJ}$$

The adiabatic flame temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields $5,857,029 / (8 + 10.48 + 3.75 + 61.1) = 70,287$ kJ/kmol. This enthalpy value corresponds to about 2150 K for N_2 . Noting that the majority of the moles are N_2 , T_P will be close to 2150 K, but somewhat under it because of the higher specific heat of H_2O .

At 2000 K:

$$8\bar{h}_{\text{CO}_2} + 10.48\bar{h}_{\text{H}_2\text{O}} + 3.75\bar{h}_{\text{O}_2} + 61.1\bar{h}_{\text{N}_2} = (8)(100,804) + (10.48)(82,593) + (3.75)(67,881) + (61.1)(64,810) = 5,886,451 \text{ kJ (Higher than 5,857,029 kJ)}$$

At 1980 K:

$$8\bar{h}_{\text{CO}_2} + 10.48\bar{h}_{\text{H}_2\text{O}} + 3.75\bar{h}_{\text{O}_2} + 61.1\bar{h}_{\text{N}_2} = (8)(99,606) + (10.48)(81,573) + (3.75)(67,127) + (61.1)(64,090) = 5,819,358 \text{ kJ (Lower than 5,857,029 kJ)}$$

By interpolation, $T_P = 1991 \text{ K}$

15-76 Problem 15-75 is reconsidered. The effect of the relative humidity on the exit temperature of the product gases is to be investigated.

Analysis The problem is solved using EES, and the solution is given below.

"The percent excess air and relative humidity are input by the diagram window."

{PercentEX = 30["%"]}

{RelHum=60["%"]}

"Other input data:"

Fuel\$ = 'Octane (C8H18)'

T_fuel = (25+273) "[K]"

Ex = PercentEX/100 "[%Excess air/100]"

P_air1 = 101.3 [kPa]

T_air1 = 25+273 "[K]"

RH_1 = RelHum/100

M_air = 28.97 [kg/kmol]

M_water = 18 [kg/kmol]

M_C8H18=(8*12+18*1) "[kg/kmol]"

"For theoretical dry air, the complete combustion equation is"

"C8H18 + A_th(O2+3.76 N2)=8 CO2+9 H2O + A_th (3.76) N2 "

A_th*2=8*2+9*1 "theoretical O balance"

"now to find the amount of water vapor associated with the dry air"

w_1=HUMRAT(AirH2O,T=T_air1,P=P_air1,R=RH_1) "Humidity ratio, kgv/kg"

N_w=w_1*((1+Ex)*A_th*4.76*M_air)/M_water "Moles of water in the atmospheric air, kmol/kmol_fuel"

"The balanced combustion equation with Ex% excess moist air is"

"C8H18 + (1+EX)[A_th(O2+3.76 N2)+N_w H2O]=8 CO2+(9+N_w) H2O + (1+Ex) A_th (3.76) N2+ Ex (A_th) O2 "

"Apply First Law SSSF"

H_fuel = -208450 [kJ/kmol] "from Table A-26"

HR=H_fuel+ (1+Ex)*A_th*enthalpy(O2,T=T_air1)+(1+Ex)*A_th*3.76

*enthalpy(N2,T=T_air1)+N_w*enthalpy(H2O,T=T_air1)

15-77 A certain coal is burned with 100 percent excess air adiabatically during a steady-flow combustion process. The temperature of product gases is to be determined for complete combustion and incomplete combustion cases.

Assumptions 1 Steady operating conditions exist. **2** Air and combustion gases are ideal gases. **3** Kinetic and potential energies are negligible. **4** There are no work interactions. **5** The combustion chamber is adiabatic.

Properties The molar masses of C, H₂, N₂, O₂, S, and air are 12, 2, 28, 32, 32, and 29 kg/kmol, respectively (Table A-1).

Analysis We consider 100 kg of coal for simplicity. Noting that the mass percentages in this case correspond to the masses of the constituents, the mole numbers of the constituent of the coal are determined to be

$$N_C = \frac{m_C}{M_C} = \frac{84.36 \text{ kg}}{12 \text{ kg/kmol}} = 7.03 \text{ kmol}$$

$$N_{H_2} = \frac{m_{H_2}}{M_{H_2}} = \frac{1.89 \text{ kg}}{2 \text{ kg/kmol}} = 0.945 \text{ kmol}$$

$$N_{O_2} = \frac{m_{O_2}}{M_{O_2}} = \frac{4.40 \text{ kg}}{32 \text{ kg/kmol}} = 0.1375 \text{ kmol}$$

$$N_{N_2} = \frac{m_{N_2}}{M_{N_2}} = \frac{0.63 \text{ kg}}{28 \text{ kg/kmol}} = 0.0225 \text{ kmol}$$

$$N_S = \frac{m_S}{M_S} = \frac{0.89 \text{ kg}}{32 \text{ kg/kmol}} = 0.0278 \text{ kmol}$$

84.36% C
1.89% H ₂
4.40% O ₂
0.63% N ₂
0.89% S
7.83% ash (by mass)

The mole number of the mixture and the mole fractions are

$$N_m = 7.03 + 0.945 + 0.1375 + 0.0225 + 0.0278 = 8.163 \text{ kmol}$$

$$y_C = \frac{N_C}{N_m} = \frac{7.03 \text{ kmol}}{8.163 \text{ kmol}} = 0.8611$$

$$y_{H_2} = \frac{N_{H_2}}{N_m} = \frac{0.945 \text{ kmol}}{8.163 \text{ kmol}} = 0.1158$$

$$y_{O_2} = \frac{N_{O_2}}{N_m} = \frac{0.1375 \text{ kmol}}{8.163 \text{ kmol}} = 0.01684$$

$$y_{N_2} = \frac{N_{N_2}}{N_m} = \frac{0.0225 \text{ kmol}}{8.163 \text{ kmol}} = 0.00276$$

$$y_S = \frac{N_S}{N_m} = \frac{0.0278 \text{ kmol}}{8.163 \text{ kmol}} = 0.003407$$

Ash consists of the non-combustible matter in coal. Therefore, the mass of ash content that enters the combustion chamber is equal to the mass content that leaves. Disregarding this non-reacting component for simplicity, the combustion equation may be written as

According to the species balances,

$$\text{C balance: } x = 0.8611$$

$$\text{H}_2 \text{ balance: } y = 0.1158$$

$$\text{S balance: } z = 0.00341$$

$$\text{O}_2 \text{ balance:}$$

$$0.01684 + 2a_{th} = 0.97x + 0.015x + 0.5y + z + a_{th}$$

$$a_{th} = (0.97)(0.8611) + (0.015)(0.8611) + (0.5)(0.1158) + 0.00341 - 0.01684 = 0.8927$$

$$\text{N}_2 \text{ balance: } 0.00276 + 2 \times 3.76a_{th} = k \longrightarrow k = 0.00276 + 2 \times 3.76 \times 0.8927 = 6.72$$

Substituting,

Under steady-flow conditions the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $Q = W = 0$ reduces to

$$\sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P = \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R \longrightarrow \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P = \sum N_R \bar{h}_{f,R}^\circ$$

From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{K}}$ kJ/kmol
O ₂	0	8682
N ₂	0	8669
H ₂ O (g)	-241,820	9904
CO	-110,530	8669
CO ₂	-110,530	8669

Thus,

$$(0.8353)(-393,520 + \bar{h}_{\text{CO}_2}) + (0.0258)(-110,530 + \bar{h}_{\text{CO}} - 8669) + (0.1158)(-241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904) \\ + (0.8927)(0 + \bar{h}_{\text{O}_2} - 8682) + (6.72)(0 + \bar{h}_{\text{N}_2} - 8669) = 0$$

It yields

$$0.8353\bar{h}_{\text{CO}_2} + 0.0258\bar{h}_{\text{CO}} + 0.1158\bar{h}_{\text{H}_2\text{O}} + 0.8927\bar{h}_{\text{O}_2} + 6.72\bar{h}_{\text{N}_2} = 434,760 \text{ kJ}$$

The product temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields

$$434,760 / (0.8353 + 0.0258 + 0.1158 + 0.00341 + 6.72 + 0.8927) = 50,595 \text{ kJ/kmol.}$$

This enthalpy value corresponds to about 1600 K for N₂. Noting that the majority of the moles are N₂, T_P will be close to 1600 K, but somewhat under it because of the higher specific heat of H₂O.

At 1500 K:

$$0.8353\bar{h}_{\text{CO}_2} + 0.0258\bar{h}_{\text{CO}} + 0.1158\bar{h}_{\text{H}_2\text{O}} + 0.9095\bar{h}_{\text{O}_2} + 6.842\bar{h}_{\text{N}_2} \\ = (0.8353)(71,078) + (0.0258)(47,517) + (0.1158)(57,999) + (0.8927)(49,292) + (6.72)(47,073) \\ = 427,647 \text{ kJ (Lower than 434,760 kJ)}$$

At 1520 K:

$$0.8353\bar{h}_{\text{CO}_2} + 0.0258\bar{h}_{\text{CO}} + 0.1158\bar{h}_{\text{H}_2\text{O}} + 0.9095\bar{h}_{\text{O}_2} + 6.842\bar{h}_{\text{N}_2} \\ = (0.8353)(72,246) + (0.0258)(48,222) + (0.1158)(58,942) + (0.8927)(50,024) + (6.72)(47,771) \\ = 434,094 \text{ kJ (Lower than 434,760 kJ)}$$

By extrapolation, $T_P = \mathbf{1522 \text{ K} = 1249^\circ\text{C}}$

We repeat the calculations for the complete combustion now:

The combustion equation in this case may be written as

According to the species balances,

C balance : $x = 0.8611$

H₂ balance : $y = 0.1158$

S balance : $z = 0.00341$

O₂ balance :

$$0.01684 + 2a_{\text{th}} = x + 0.5y + z + a_{\text{th}} \longrightarrow a_{\text{th}} = 0.8611 + (0.5)(0.1158) + 0.00341 - 0.01684 = 0.9056$$

$$\text{N}_2 \text{ balance : } 0.00276 + 2 \times 3.76a_{\text{th}} = k \longrightarrow k = 0.00276 + 2 \times 3.76 \times 0.9056 = 6.81$$

Substituting,

$$0.8611\text{C} + 0.1158\text{H}_2 + 0.01684\text{O}_2 + 0.00276\text{N}_2 + 0.003407\text{S} + 1.819(\text{O}_2 + 3.76\text{N}_2) \\ \longrightarrow 0.8611\text{CO}_2 + 0.1158\text{H}_2\text{O} + 0.00341\text{SO}_2 + 6.81\text{N}_2 + 0.9056\text{O}_2$$

Under steady-flow conditions the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $Q = W = 0$ reduces to

$$\sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P = \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R \longrightarrow \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P = \sum N_R \bar{h}_{f,R}^\circ$$

From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{K}}$ kJ/kmol
O ₂	0	8682
N ₂	0	8669
H ₂ O (g)	-241,820	9904
CO	-110,530	8669
CO ₂	0	8682

Thus,

$$(0.8611)(-393,520 + \bar{h}_{\text{CO}_2} - 9364) + (0.1158)(-241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904) \\ + (0.9056)(0 + \bar{h}_{\text{O}_2} - 8682) + (6.81)(0 + \bar{h}_{\text{N}_2} - 8669) = 0$$

It yields

$$0.8611\bar{h}_{\text{CO}_2} + 0.1158\bar{h}_{\text{H}_2\text{O}} + 0.9056\bar{h}_{\text{O}_2} + 6.81\bar{h}_{\text{N}_2} = 442,971 \text{ kJ}$$

The product temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields

$$442,971 / (0.8611 + 0.1158 + 0.00341 + 6.81 + 0.9056) = 50,940 \text{ kJ/kmol.}$$

This enthalpy value corresponds to about 1600 K for N₂. Noting that the majority of the moles are N₂, T_p will be close to 1600 K, but somewhat under it because of the higher specific heat of H₂O.

At 1500 K:

$$0.8611\bar{h}_{\text{CO}_2} + 0.1158\bar{h}_{\text{H}_2\text{O}} + 0.9056\bar{h}_{\text{O}_2} + 6.81\bar{h}_{\text{N}_2} \\ = (0.8611)(71,078) + (0.1158)(57,999) + (0.9056)(49,292) + (6.81)(47,073) \\ = 433,128 \text{ kJ (Lower than 442,971 kJ)}$$

At 1520 K:

$$0.8611\bar{h}_{\text{CO}_2} + 0.1158\bar{h}_{\text{H}_2\text{O}} + 0.9056\bar{h}_{\text{O}_2} + 6.81\bar{h}_{\text{N}_2} \\ = (0.8611)(72,246) + (0.1158)(58,942) + (0.9056)(50,024) + (6.81)(47,771) \\ = 439,658 \text{ kJ (Lower than 442,971 kJ)}$$

By extrapolation, $T_p = \mathbf{1530 \text{ K} = 1257^\circ\text{C}}$

15-78 A mixture of hydrogen and the stoichiometric amount of air contained in a constant-volume tank is ignited. The final temperature in the tank is to be determined.

Assumptions 1 The tank is adiabatic. **2** Both the reactants and products are ideal gases. **3** There are no work interactions. **4** Combustion is complete.

Analysis The combustion equation of H_2 with stoichiometric amount of air is

The final temperature in the tank is determined from the energy balance relation $E_{in} - E_{out} = \Delta E_{system}$ for reacting closed systems under adiabatic conditions ($Q = 0$) with no work interactions ($W = 0$),

$$\sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_P = \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_R$$

Since both the reactants and the products behave as ideal gases, all the internal energy and enthalpies depend on temperature only, and the $P\bar{v}$ terms in this equation can be replaced by $R_u T$.

It yields

$$\sum N_P (\bar{h}_f^\circ + \bar{h}_{T_P} - \bar{h}_{298K} - R_u T)_P = \sum N_R (\bar{h}_f^\circ R_u T)_R$$

since the reactants are at the standard reference temperature of 25°C . From the tables,

Substance	\bar{h}_f°	$\bar{h}_{298\text{ K}}$
	kJ/kmol	kJ/kmol
H_2	0	8468
O_2	0	8682
N_2	0	8669
$H_2O(g)$	-241,820	9904

Thus,

$$\begin{aligned} (1)(-241,820 + \bar{h}_{H_2O} - 9904 - 8.314 \times T_P) + (1.88)(0 + \bar{h}_{N_2} - 8669 - 8.314 \times T_P) \\ = (1)(0 - 8.314 \times 298) + (0.5)(0 - 8.314 \times 298) + (1.88)(0 - 8.314 \times 298) \end{aligned}$$

It yields

$$\bar{h}_{H_2O} + 1.88\bar{h}_{N_2} - 23.94 \times T_P = 259,648 \text{ kJ}$$

The temperature of the product gases is obtained from a trial and error solution,

$$\begin{aligned} \text{At } 3050 \text{ K: } \quad \bar{h}_{H_2O} + 1.88\bar{h}_{N_2} - 23.94 \times T_P &= (1)(139,051) + (1.88)(103,260) - (23.94)(3050) \\ &= 260,163 \text{ kJ (Higher than } 259,648 \text{ kJ)} \end{aligned}$$

$$\begin{aligned} \text{At } 3000 \text{ K: } \quad \bar{h}_{H_2O} + 1.88\bar{h}_{N_2} - 23.94 \times T_P &= (1)(136,264) + (1.88)(101,407) - (23.94)(3000) \\ &= 255,089 \text{ kJ (Lower than } 259,648 \text{ kJ)} \end{aligned}$$

By interpolation,

$$T_P = \mathbf{3045 \text{ K}}$$

15-79 Methane is burned with 200 percent excess air adiabatically in a constant volume container. The final pressure and temperature of product gases are to be determined.

Assumptions 1 Air and combustion gases are ideal gases. **3** Kinetic and potential energies are negligible. **4** There are no work interactions. **5** The combustion chamber is adiabatic.

Analysis The combustion equation is

where a_{th} is the stoichiometric coefficient and is determined from the O_2 balance,

$$3a_{\text{th}} = 1 + 1 + 2a_{\text{th}} \longrightarrow a_{\text{th}} = 2$$

Substituting, $\text{CH}_4 + 6[\text{O}_2 + 3.76\text{N}_2] \longrightarrow \text{CO}_2 + 2\text{H}_2\text{O} + 22.56\text{N}_2 + 4\text{O}_2$

For this constant-volume process, the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $Q = W = 0$ reduces to

$$\sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_P = \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_R$$

Since both the reactants and products are assumed to be ideal gases, all the internal energy and enthalpies depend on temperature only, and the $P\bar{v}$ terms in this equation can be replaced by $R_u T$. It yields

$$\sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - R_u T)_P = \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - R_u T)_R$$

From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{K}}$ kJ/kmol
$\text{CH}_4(g)$	-74,850	---
O_2	0	8682
N_2	0	8669
$\text{H}_2\text{O}(g)$	-241,820	9904
CO_2	-393,520	9364

Thus,

$$\begin{aligned} & (1)(-393,520 + \bar{h}_{\text{CO}_2} - 9364 - 8.314 \times T_p) + (2)(-241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904 - 8.314 \times T_p) \\ & + (4)(0 + \bar{h}_{\text{O}_2} - 8682 - 8.314 \times T_p) + (22.56)(0 + \bar{h}_{\text{N}_2} - 8669 - 8.314 \times T_p) \\ & = (1)(-74,850 - 8.314 \times 298) + (6)(0 - 8.314 \times 298) + (22.56)(-8.314 \times 298) \end{aligned}$$

It yields $\bar{h}_{\text{CO}_2} + 2\bar{h}_{\text{H}_2\text{O}} + 4\bar{h}_{\text{O}_2} + 22.56\bar{h}_{\text{N}_2} - 245.8T_p = -148,087 + 1,136,633 = 988,546 \text{ kJ}$

The adiabatic flame temperature is obtained from a trial and error solution. A first guess may be obtained by assuming all the products are nitrogen and using nitrogen enthalpy in the above equation. That is,

$$29.56\bar{h}_{\text{N}_2} - 245.8T_p = 988,546 \text{ kJ}$$

An investigation of Table A-18 shows that this equation is satisfied at a temperature close to 1460 K but it will be somewhat under it because of the higher specific heat of H_2O .

At 1380 K: $(64,116) + (2)(52,434) + (4)(44,923) + (22.56)(42,915) - (245.8)(1380) = 977,634$
(Lower than 988,546 kJ)

At 1400 K: $(65,271) + (2)(53,351) + (4)(45,648) + (22.56)(43,605) - (245.8)(1400) = 994,174$
(Higher than 988,546 kJ)

By interpolation, $T_p = \mathbf{1393 \text{ K}}$

The volume of reactants when 1 kmol of fuel is burned is

$$\mathcal{V} = \mathcal{V}_{\text{fuel}} + \mathcal{V}_{\text{air}} = (N_{\text{fuel}} + N_{\text{air}}) \frac{R_u T}{P} = (1 + 28.56) \text{ kmol} \frac{(8.314 \text{ kJ/kmol} \cdot \text{K})(298 \text{ K})}{101.3 \text{ kPa}} = 723.0 \text{ m}^3$$

The final pressure is then

$$P = N_{\text{prod}} \frac{R_u T}{\mathcal{V}} = (29.56 \text{ kmol}) \frac{(8.314 \text{ kJ/kmol} \cdot \text{K})(1393 \text{ K})}{723.0 \text{ m}^3} = \mathbf{474 \text{ kPa}}$$

Entropy Change and Second Law Analysis of Reacting Systems

15-80C Assuming the system exchanges heat with the surroundings at T_0 , the increase-in-entropy principle can be expressed as

$$S_{\text{gen}} = \sum N_P \bar{s}_P - \sum N_R \bar{s}_R + \frac{Q_{\text{out}}}{T_0}$$

15-81C By subtracting $R \ln(P/P_0)$ from the tabulated value at 1 atm. Here P is the actual pressure of the substance and P_0 is the atmospheric pressure.

15-82C It represents the reversible work associated with the formation of that compound.

15-83 Liquid octane is burned steadily with 50 percent excess air. The heat transfer rate from the combustion chamber, the entropy generation rate, and the reversible work and exergy destruction rate are to be determined.

Assumptions 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.

Analysis (a) The fuel is burned completely with the excess air, and thus the products will contain only CO_2 , H_2O , N_2 , and some free O_2 . Considering 1 kmol C_8H_{18} , the combustion equation can be written as

where a_{th} is the stoichiometric coefficient and is determined from the O_2 balance,

$$1.5a_{\text{th}} = 8 + 4.5 + 0.5a_{\text{th}} \longrightarrow a_{\text{th}} = 12.5$$

Thus,

Under steady-flow conditions the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $W = 0$ reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R = \sum N_P \bar{h}_{f,P}^\circ - \sum N_R \bar{h}_{f,R}^\circ$$

since all of the reactants are at 25°C . Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° kJ/kmol
$\text{C}_8\text{H}_{18}(\ell)$	-249,950
O_2	0
N_2	0
$\text{H}_2\text{O}(l)$	-285,830
CO_2	-393,520

Substituting,

$$-Q_{\text{out}} = (8)(-393,520) + (9)(-285,830) + 0 + 0 - (1)(-249,950) - 0 - 0 = -5,470,680 \text{ kJ/kmol of } \text{C}_8\text{H}_{18} \text{ or}$$

or

$$Q_{\text{out}} = 5,470,680 \text{ kJ/kmol of } \text{C}_8\text{H}_{18}$$

The C_8H_{18} is burned at a rate of 0.25 kg/min or

$$\dot{N} = \frac{\dot{m}}{M} = \frac{0.25 \text{ kg/min}}{[(8)(12) + (18)(1)] \text{ kg/kmol}} = 2.193 \times 10^{-3} \text{ kmol/min}$$

Thus,

$$\dot{Q}_{\text{out}} = \dot{N} Q_{\text{out}} = (2.193 \times 10^{-3} \text{ kmol/min})(5,470,680 \text{ kJ/kmol}) = \mathbf{11,997 \text{ kJ/min}}$$

The heat transfer for this process is also equivalent to the enthalpy of combustion of liquid C_8H_{18} , which could easily be determined from Table A-27 to be $\bar{h}_c = 5,470,740 \text{ kJ/kmol } \text{C}_8\text{H}_{18}$.

(b) The entropy generation during this process is determined from

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{out}}}{T_{\text{surr}}} \longrightarrow S_{\text{gen}} = \sum N_P \bar{s}_P - \sum N_R \bar{s}_R + \frac{Q_{\text{out}}}{T_{\text{surr}}}$$

The C_8H_{18} is at $25^\circ C$ and 1 atm, and thus its absolute entropy is $\bar{s}_{C_8H_{18}} = 360.79 \text{ kJ/kmol}\cdot K$ (Table A-26). The entropy values listed in the ideal gas tables are for 1 atm pressure. Both the air and the product gases are at a total pressure of 1 atm, but the entropies are to be calculated at the partial pressure of the components which is equal to $P_i = y_i P_{\text{total}}$, where y_i is the mole fraction of component i . Also,

$$S_i = N_i \bar{s}_i(T, P_i) = N_i \left(\bar{s}_i^\circ(T, P_0) - R_u \ln(y_i P_m) \right)$$

The entropy calculations can be presented in tabular form as

	N_i	y_i	$\bar{s}_i^\circ(\mathbf{T}, \mathbf{1atm})$	$R_u \ln(y_i P_m)$	$N_i \bar{s}_i$
C_8H_{18}	1	1.00	360.79	---	360.79
O_2	18.75	0.21	205.14	-12.98	4089.75
N_2	70.50	0.79	191.61	-1.96	13646.69
$S_R = 18,097.23 \text{ kJ/K}$					
CO_2	8	0.0944	213.80	-19.62	1867.3
$H_2O (\ell)$	9	---	69.92	---	629.3
O_2	6.25	0.0737	205.04	-21.68	1417.6
N_2	70.50	0.8319	191.61	-1.53	13,616.3
$S_P = 17,531 \text{ kJ/K}$					

Thus,

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{surr}}}{T_{\text{surr}}} = 17,531 - 18,097 + \frac{5,470,523 \text{ kJ}}{298 \text{ K}} = 17,798 \text{ kJ/kmol}\cdot K$$

and

$$\dot{S}_{\text{gen}} = \dot{N} S_{\text{gen}} = (2.193 \times 10^{-3} \text{ kmol/min})(17,798 \text{ kJ/kmol}\cdot K) = \mathbf{39.03 \text{ kJ/min}\cdot K}$$

(c) The exergy destruction rate associated with this process is determined from

$$\dot{X}_{\text{destroyed}} = T_0 \dot{S}_{\text{gen}} = (298 \text{ K})(39.03 \text{ kJ/min}\cdot K) = 11,632 \text{ kJ/min} = \mathbf{193.9 \text{ kW}}$$

15-84E Benzene gas is burned steadily with 90 percent theoretical air. The heat transfer rate from the combustion chamber and the exergy destruction are to be determined.

Assumptions 1 Steady operating conditions exist. **2** Air and the combustion gases are ideal gases. **3** Changes in kinetic and potential energies are negligible.

Analysis (a) The fuel is burned with insufficient amount of air, and thus the products will contain some CO as well as CO₂, H₂O, and N₂. The theoretical combustion equation of C₆H₆ is

where a_{th} is the stoichiometric coefficient and is determined from the O₂ balance,

$$a_{\text{th}} = 6 + 1.5 = 7.5$$

Then the actual combustion equation can be written as

The value of x is determined from an O₂ balance,

$$(0.90)(7.5) = x + (6-x)/2 + 1.5 \longrightarrow x = 4.5$$

Thus,

Under steady-flow conditions the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $W = 0$ reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R \bar{h}_{f,R}^\circ$$

since all of the reactants are at 77°F. Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$.

From the tables,

Substance	\bar{h}_f° Btu/lbmol	$\bar{h}_{537\text{ R}}$ Btu/lbmol	$\bar{h}_{1900\text{ R}}$ Btu/lbmol
C ₆ H ₆ (g)	35,680	---	---
O ₂	0	3725.1	14,322
N ₂	0	3729.5	13,742
H ₂ O (g)	-104,040	4258.0	16,428
CO	-47,540	3725.1	13,850
CO ₂	-169,300	4027.5	19,698

Thus,

$$\begin{aligned} -Q_{\text{out}} &= (4.5)(-169,300 + 19,698 - 4027.5) + (1.5)(-47,540 + 13,850 - 3725.1) \\ &\quad + (3)(-104,040 + 16,428 - 4258) + (25.38)(0 + 13,742 - 3729.5) - (1)(35,680) - 0 - 0 \\ &= \mathbf{-804,630 \text{ Btu/lbmol of C}_6\text{H}_6} \end{aligned}$$

(b) The entropy generation during this process is determined from

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{out}}}{T_{\text{surr}}} = \sum N_P \bar{s}_P - \sum N_R \bar{s}_R + \frac{Q_{\text{out}}}{T_{\text{surr}}}$$

The C_6H_6 is at 77°F and 1 atm, and thus its absolute entropy is $\bar{s}_{C_6H_6} = 64.34$ Btu/lbmol·R (Table A-26E). The entropy values listed in the ideal gas tables are for 1 atm pressure. Both the air and the product gases are at a total pressure of 1 atm, but the entropies are to be calculated at the partial pressure of the components which is equal to $P_i = y_i P_{total}$, where y_i is the mole fraction of component i . Also,

$$S_i = N_i \bar{s}_i(T, P_i) = N_i (\bar{s}_i^\circ(T, P_0) - R_u \ln(y_i P_m))$$

The entropy calculations can be presented in tabular form as

	N_i	y_i	$\bar{s}_i^\circ(T, 1\text{atm})$	$R_u \ln(y_i P_m)$	$N_i \bar{s}_i$
C_6H_6	1	1.00	64.34	---	64.34
O_2	6.75	0.21	49.00	-3.10	351.68
N_2	25.38	0.79	45.77	-0.47	1173.57
					$S_R = 1589.59$ Btu/R
CO_2	4.5	0.1309	64.999	-4.038	310.67
CO	1.5	0.0436	56.509	-6.222	94.10
$H_2O(g)$	3	0.0873	56.097	-4.843	182.82
N_2	25.38	0.7382	54.896	-0.603	1408.56
					$S_P = 1996.15$ Btu/R

Thus,

$$S_{gen} = S_P - S_R + \frac{Q_{out}}{T_{sur}} = 1996.15 - 1589.59 + \frac{804,630}{537} = 1904.9 \text{ Btu/R}$$

Then the exergy destroyed is determined from

$$X_{destroyed} = T_0 S_{gen} = (537 \text{ R})(1904.9 \text{ Btu/lbmol} \cdot \text{R}) = \mathbf{1,022,950 \text{ Btu/R}} \text{ (per lbmol } C_6H_6 \text{)}$$

15-85 Liquid propane is burned steadily with 150 percent excess air. The mass flow rate of air, the heat transfer rate from the combustion chamber, and the rate of entropy generation are to be determined.

Assumptions 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.

Properties The molar masses of C_3H_8 and air are 44 kg/kmol and 29 kg/kmol, respectively (Table A-1).

Analysis (a) The fuel is burned completely with the excess air, and thus the products will contain only CO_2 , H_2O , N_2 , and some free O_2 . Considering 1 kmol of C_3H_8 , the combustion equation can be written as

where a_{th} is the stoichiometric coefficient and is determined from the O_2 balance,

$$2.5a_{th} = 3 + 2 + 1.5a_{th} \longrightarrow a_{th} = 5$$

Substituting,

The air-fuel ratio for this combustion process is

$$AF = \frac{m_{air}}{m_{fuel}} = \frac{(12.5 \times 4.76 \text{ kmol})(29 \text{ kg/kmol})}{(3 \text{ kmol})(12 \text{ kg/kmol}) + (4 \text{ kmol})(2 \text{ kg/kmol})} = 39.2 \text{ kg air/kg fuel}$$

Thus,

$$\dot{m}_{air} = (AF)(\dot{m}_{fuel}) = (39.2 \text{ kg air/kg fuel})(0.4 \text{ kg fuel/min}) = \mathbf{15.7 \text{ kg air/min}}$$

(b) Under steady-flow conditions the energy balance $E_{in} - E_{out} = \Delta E_{system}$ applied on the combustion chamber with $W = 0$ reduces to

$$-Q_{out} = \sum N_P(\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R(\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. From the tables, (The \bar{h}_f° of liquid propane is obtained by adding the h_{fg} at $25^\circ C$ to \bar{h}_f° of gaseous propane).

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{285 \text{ K}}$ kJ/kmol	$\bar{h}_{298 \text{ K}}$ kJ/kmol	$\bar{h}_{1200 \text{ K}}$ kJ/kmol
$C_3H_8(\ell)$	-118,910	---	---	---
O_2	0	8296.5	8682	38,447
N_2	0	8286.5	8669	36,777
$H_2O(g)$	-241,820	---	9904	44,380
CO_2	-393,520	---	9364	53,848

Thus,

$$\begin{aligned} -Q_{out} &= (3)(-393,520 + 53,848 - 9364) + (4)(-241,820 + 44,380 - 9904) \\ &\quad + (7.5)(0 + 38,447 - 8682) + (47)(0 + 36,777 - 8669) - (1)(-118,910 + h_{298} - h_{298}) \\ &\quad - (12.5)(0 + 8296.5 - 8682) - (47)(0 + 8286.5 - 8669) \\ &= -190,464 \text{ kJ/kmol of } C_3H_8 \end{aligned}$$

Thus 190,464 kJ of heat is transferred from the combustion chamber for each kmol (44 kg) of propane. This corresponds to $190,464/44 = 4328.7$ kJ of heat transfer per kg of propane. Then the rate of heat transfer for a mass flow rate of 0.4 kg/min for the propane becomes

$$\dot{Q}_{\text{out}} = \dot{m}q_{\text{out}} = (0.4 \text{ kg/min})(4328.7 \text{ kJ/kg}) = \mathbf{1732 \text{ kJ/min}}$$

(c) The entropy generation during this process is determined from

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{out}}}{T_{\text{surr}}} = \sum N_P \bar{s}_P - \sum N_R \bar{s}_R + \frac{Q_{\text{out}}}{T_{\text{surr}}}$$

The C_3H_8 is at 25°C and 1 atm, and thus its absolute entropy for the gas phase is $\bar{s}_{\text{C}_3\text{H}_8} = 269.91 \text{ kJ/kmol}\cdot\text{K}$ (Table A-26).

Then the entropy of $\text{C}_3\text{H}_8(\ell)$ is obtained from

$$s_{\text{C}_3\text{H}_8}(\ell) \cong s_{\text{C}_3\text{H}_8}(\text{g}) - s_{fg} = s_{\text{C}_3\text{H}_8}(\text{g}) - \frac{\bar{h}_{fg}}{T} = 269.91 - \frac{15,060}{298.15} = 219.4 \text{ kJ/kmol}\cdot\text{K}$$

The entropy values listed in the ideal gas tables are for 1 atm pressure. Both the air and the product gases are at a total pressure of 1 atm, but the entropies are to be calculated at the partial pressure of the components which is equal to $P_i = y_i P_{\text{total}}$, where y_i is the mole fraction of component i . Then,

$$S_i = N_i \bar{s}_i(T, P_i) = N_i \left(\bar{s}_i^\circ(T, P_0) - R_u \ln(y_i P_m) \right)$$

The entropy calculations can be presented in tabular form as

	N_i	y_i	$\bar{s}_i^\circ(\mathbf{T}, 1\text{atm})$	$R_u \ln(y_i P_m)$	$N_i \bar{s}_i$
C_3H_8	1	---	219.40	---	219.40
O_2	12.5	0.21	203.70	-12.98	2708.50
N_2	47	0.79	190.18	-1.96	9030.58
					$S_R = 11,958.48 \text{ kJ/K}$
CO_2	3	0.0488	279.307	-25.112	913.26
$\text{H}_2\text{O}(\text{g})$	4	0.0650	240.333	-22.720	1052.21
O_2	7.5	0.1220	249.906	-17.494	2005.50
N_2	47	0.7642	234.115	-2.236	11108.50
					$S_P = 15,079.47 \text{ kJ/K}$

Thus,

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{out}}}{T_{\text{surr}}} = 15,079.47 - 11,958.48 + \frac{190,464}{298} = 3760.1 \text{ kJ/K (per kmol } \text{C}_3\text{H}_8 \text{)}$$

Then the rate of entropy generation becomes

$$\dot{S}_{\text{gen}} = (\dot{N})(S_{\text{gen}}) = \left(\frac{0.4}{44} \text{ kmol/min} \right) (3760.1 \text{ kJ/kmol}\cdot\text{K}) = \mathbf{34.2 \text{ kJ/min}\cdot\text{K}}$$

15-86 Problem 15-85 is reconsidered. The effect of the surroundings temperature on the rate of exergy destruction is to be studied.

Analysis The problem is solved using EES, and the solution is given below.

```

15-87 Liquid octane is burned steadily with 70 percent excess air. The entropy generation and exergy destruction per unit mass of the fuel are to be determined.

Assumptions 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.

Properties The molar masses of C_8H_{18} and air are 114 kg/kmol and 29 kg/kmol, respectively (Table A-1).

Analysis The fuel is burned completely with the excess air, and thus the products will contain only CO_2 , H_2O , N_2 , and some free O_2 . Considering 1 kmol C_8H_{18} , the combustion equation can be written as

where a_{th} is the stoichiometric coefficient and is determined from the O_2 balance,

$$1.7a_{th} = 8 + 4.5 + 0.7a_{th} \longrightarrow a_{th} = 12.5$$

Thus,

(b) Under steady-flow conditions the energy balance $E_{in} - E_{out} = \Delta E_{system}$ applied on the combustion chamber with $W = 0$ reduces to

$$-Q_{out} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° kJ/kmol	\bar{h}_{298K} kJ/kmol	\bar{h}_{600K} kJ/kmol	\bar{h}_{1340K} kJ/kmol
$C_8H_{18}(\ell)$	-249,950	---	---	---
O_2	0	8682	17,929	43,475
N_2	0	8669	17,563	41,539
$H_2O(g)$	-241,820	9904	---	50,612
CO_2	-393,520	9364	---	61,813

Thus,

$$\begin{aligned} -Q_{out} &= (8)(-393,520 + 61,813 - 9364) + (9)(-241,820 + 50,612 - 9904) \\ &\quad + (8.75)(0 + 43,475 - 8682) + (79.9)(0 + 41,539 - 8669) - (1)(-249,950) \\ &\quad - (21.25)(0 + 17,929 - 8682) - (79.9)(0 + 17,563 - 8669) \\ &= -2,265,004 \text{ kJ/kmol of } C_8H_{18} \end{aligned}$$

The entropy generation during this process is determined from

$$S_{gen} = S_P - S_R + \frac{Q_{out}}{T_{surr}} = \sum N_P \bar{s}_P - \sum N_R \bar{s}_R + \frac{Q_{out}}{T_{surr}}$$

The entropy values listed in the ideal gas tables are for 1 atm pressure. Both the air and the product gases are at a total pressure of $P_m = 600 \text{ kPa}$ ($=600/101.325=5.92 \text{ atm}$), but the entropies are to be calculated at the partial pressure of the components which is equal to $P_i = y_i P_{total}$, where y_i is the mole fraction of component i . Then,

$$S_i = N_i \bar{s}_i(T, P_i) = N_i \left(\bar{s}_i^\circ(T, P_0) - R_u \ln(y_i P_m) \right)$$

The entropy calculations can be presented in tabular form as

	N_i	y_i	$\bar{s}_i^\circ(T, 1\text{atm})$	$R_u \ln(y_i P_m)$	$N_i \bar{s}_i$
C_8H_{18}	1	---	466.73	14.79	451.94
O_2	21.25	0.21	226.35	1.81	4771.48
N_2	79.9	0.79	212.07	12.83	15,919.28
					$S_R = 21,142.70 \text{ kJ/K}$
CO_2	8	0.0757	292.11	-6.673	2390.26
$H_2O(g)$	9	0.0852	250.45	-5.690	2305.26
O_2	8.75	0.0828	257.97	-5.928	2309.11
N_2	79.9	0.7563	241.77	12.46	18,321.87
					$S_P = 25,326.50 \text{ kJ/K}$

Thus,

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{out}}}{T_{\text{surr}}} = 25,326.50 - 21,142.70 + \frac{2,265,004}{298} = 11,784.5 \text{ kJ/K (per kmol } C_8H_{18}\text{)}$$

The exergy destruction is

$$X_{\text{dest}} = T_0 S_{\text{gen}} = (298)(11,784.5 \text{ kJ/K}) = 3,511,776 \text{ kJ/K (per kmol } C_8H_{18}\text{)}$$

The entropy generation and exergy destruction per unit mass of the fuel are

$$S_{\text{gen}} = \frac{\bar{S}_{\text{gen}}}{M_{\text{fuel}}} = \frac{11,784.5 \text{ kJ/K} \cdot \text{kmol}}{114 \text{ kg/kmol}} = \mathbf{103.4 \text{ kJ/K} \cdot \text{kg } C_8H_{18}}$$

$$X_{\text{dest}} = \frac{\bar{X}_{\text{dest}}}{M_{\text{fuel}}} = \frac{3,511,776 \text{ kJ/K} \cdot \text{kmol}}{114 \text{ kg/kmol}} = \mathbf{30,805 \text{ kJ/kg } C_8H_{18}}$$

15-88 Methyl alcohol is burned steadily with 200 percent excess air in an automobile engine. The maximum amount of work that can be produced by this engine is to be determined.

Assumptions 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.

Analysis The fuel is burned completely with the excess air, and thus the products will contain only CO_2 , H_2O , N_2 , and some free O_2 . Considering 1 kmol CH_3OH the combustion equation can be written as

where a_{th} is the stoichiometric coefficient and is determined from the O_2 balance,

$$0.5 + 3a_{\text{th}} = 1 + 1 + 2a_{\text{th}} \longrightarrow a_{\text{th}} = 1.5$$

Thus,

Under steady-flow conditions the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $W = 0$ reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{K}}$ kJ/kmol	$\bar{h}_{350\text{K}}$ kJ/kmol
CH_3OH	-200,670	---	---
O_2	0	8682	10,213
N_2	0	8669	10,180
$\text{H}_2\text{O} (g)$	-241,820	9904	11,652
CO_2	-393,520	9364	11,351

Thus,

$$\begin{aligned} -Q_{\text{out}} &= (1)(-393,520 + 11,351 - 9364) + (2)(-241,820 + 11,652 - 9904) \\ &\quad + (3)(0 + 10,213 - 8682) + (16.92)(0 + 10,180 - 8669) - (1)(-200,670) \\ &= -663,550 \text{ kJ/kmol of fuel} \end{aligned}$$

The entropy generation during this process is determined from

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{out}}}{T_{\text{sur}}} = \sum N_P \bar{s}_P - \sum N_R \bar{s}_R + \frac{Q_{\text{out}}}{T_{\text{sur}}}$$

The entropy values listed in the ideal gas tables are for 1 atm pressure. Both the air and the product gases are at a total pressure of 1 atm, but the entropies are to be calculated at the partial pressure of the components which is equal to $P_i = y_i P_{\text{total}}$, where y_i is the mole fraction of component i . Then,

$$S_i = N_i \bar{s}_i(T, P_i) = N_i \left(\bar{s}_i^\circ(T, P_0) - R_u \ln(y_i P_m) \right)$$

The entropy calculations can be presented in tabular form as

	N_i	y_i	$\bar{s}_i^\circ(T, 1\text{atm})$	$R_u \ln(y_i P_m)$	$N_i \bar{s}_i$
CH ₃ OH	1	---	239.70	---	239.70
O ₂	4.5	0.21	205.04	-12.98	981.09
N ₂	16.92	0.79	191.61	-1.960	3275.20
					$S_R = 4496 \text{ kJ/K}$
CO ₂	1	0.0436	219.831	-26.05	245.88
H ₂ O (g)	2	0.0873	194.125	-20.27	428.79
O ₂	3	0.1309	209.765	-16.91	680.03
N ₂	16.92	0.7382	196.173	-2.52	3361.89
					$S_P = 4717 \text{ kJ/K}$

Thus,

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{out}}}{T_{\text{surr}}} = 4717 - 4496 + \frac{663,550}{298} = 2448 \text{ kJ/K (per kmol fuel)}$$

The maximum work is equal to the exergy destruction

$$W_{\text{max}} = X_{\text{dest}} = T_0 S_{\text{gen}} = (298)(2448 \text{ kJ/K}) = 729,400 \text{ kJ/K (per kmol fuel)}$$

Per unit mass basis,

$$W_{\text{max}} = \frac{729,400 \text{ kJ/K} \cdot \text{kmol}}{32 \text{ kg/kmol}} = \mathbf{22,794 \text{ kJ/kg fuel}}$$

15-89 CO gas is burned steadily with air. The heat transfer rate from the combustion chamber and the rate of exergy destruction are to be determined.

Assumptions 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.

Properties The molar masses of CO and air are 28 kg/kmol and 29 kg/kmol, respectively (Table A-1).

Analysis (a) We first need to calculate the amount of air used per kmol of CO before we can write the combustion equation,

$$\nu_{\text{CO}} = \frac{RT}{P} = \frac{(0.2968 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(310 \text{ K})}{110 \text{ kPa}} = 0.836 \text{ m}^3/\text{kg}$$

$$\dot{m}_{\text{CO}} = \frac{\dot{V}_{\text{CO}}}{\nu_{\text{CO}}} = \frac{0.4 \text{ m}^3/\text{min}}{0.836 \text{ m}^3/\text{kg}} = 0.478 \text{ kg/min}$$

Then the molar air-fuel ratio becomes

$$\overline{\text{AF}} = \frac{N_{\text{air}}}{N_{\text{fuel}}} = \frac{\dot{m}_{\text{air}} / M_{\text{air}}}{\dot{m}_{\text{fuel}} / M_{\text{fuel}}} = \frac{(1.5 \text{ kg/min}) / (29 \text{ kg/kmol})}{(0.478 \text{ kg/min}) / (28 \text{ kg/kmol})} = 3.03 \text{ kmol air/kmol fuel}$$

Thus the number of moles of O_2 used per mole of CO is $3.03/4.76 = 0.637$. Then the combustion equation in this case can be written as

Under steady-flow conditions the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $W = 0$ reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298 \text{ K}}$ kJ/kmol	$\bar{h}_{310 \text{ K}}$ kJ/kmol	$\bar{h}_{900 \text{ K}}$ kJ/kmol
CO	-110,530	8669	9014	---
O_2	0	8682	---	27,928
N_2	0	8669	---	26,890
CO_2	-393,520	9364	---	37,405

Substituting,

$$\begin{aligned} -Q_{\text{out}} &= (1)(-393,520 + 37,405 - 9364) + (0.137)(0 + 27,928 - 8682) \\ &\quad + (2.4)(0 + 26,890 - 8669) - (1)(-110,530 + 9014 - 8669) - 0 - 0 \\ &= -208,929 \text{ kJ/kmol of CO} \end{aligned}$$

Thus 208,929 kJ of heat is transferred from the combustion chamber for each kmol (28 kg) of CO. This corresponds to $208,929/28 = 7462$ kJ of heat transfer per kg of CO. Then the rate of heat transfer for a mass flow rate of 0.478 kg/min for CO becomes

$$\dot{Q}_{\text{out}} = \dot{m}_{\text{CO}} (7462 \text{ kJ/kg}) = \mathbf{3567 \text{ kJ/min}}$$

(b) This process involves heat transfer with a reservoir other than the surroundings. An exergy balance on the combustion chamber in this case reduces to the following relation for reversible work,

$$W_{\text{rev}} = \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - T_0 \bar{s})_R - \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - T_0 \bar{s})_P - Q_{\text{out}} (1 - T_0 / T_R)$$

The entropy values listed in the ideal gas tables are for 1 atm = 101.325 kPa pressure. The entropy of each reactant and the product is to be calculated at the partial pressure of the components which is equal to $P_i = y_i P_{\text{total}}$, where y_i is the mole fraction of component i , and $P_m = 110/101.325 = 1.0856$ atm. Also,

PROPRIETARY MATERIAL. © 2015 McGraw-Hill Education. Limited distribution permitted only to teachers and educators for course preparation. If you are a student using this Manual, you are using it without permission.

$$S_i = N_i \bar{s}_i(T, P_i) = N_i (\bar{s}_i^\circ(T, P_0) - R_u \ln(y_i P_m))$$

The entropy calculations can be presented in tabular form as

	N_i	y_i	$\bar{s}_i^\circ(\mathbf{T}, 1\text{atm})$	$R_u \ln(y_i P_m)$	$N_i \bar{s}_i$
CO	1	1.00	198.678	0.68	198.00
O ₂	0.637	0.21	205.04	-12.29	138.44
N ₂	2.400	0.79	191.61	-1.28	462.94
					$S_R = 799.38 \text{ kJ/K}$
CO ₂	1	0.2827	263.559	-9.821	273.38
O ₂	0.137	0.0387	239.823	-26.353	36.47
N ₂	2.400	0.6785	224.467	-2.543	544.82
					$S_P = 854.67 \text{ kJ/K}$

The rate of exergy destruction can be determined from

$$\dot{X}_{\text{destroyed}} = T_0 \dot{S}_{\text{gen}} = T_0 \dot{m} (S_{\text{gen}} / M)$$

where

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{out}}}{T_{\text{res}}} = 854.67 - 799.38 + \frac{208,929 \text{ kJ}}{800 \text{ K}} = 316.5 \text{ kJ/kmol} \cdot \text{K}$$

Thus,

$$\dot{X}_{\text{destroyed}} = (298 \text{ K})(0.478 \text{ kg/min})(316.5/28 \text{ kJ/kmol} \cdot \text{K}) = \mathbf{1610 \text{ kJ/min}}$$

15-90 Acetylene gas is burned steadily with 20 percent excess air. The temperature of the products, the total entropy change, and the exergy destruction are to be determined.

Assumptions 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.

Analysis (a) The fuel is burned completely with the excess air, and thus the products will contain only CO_2 , H_2O , N_2 , and some free O_2 . Considering 1 kmol C_2H_2 , the combustion equation can be written as

where a_{th} is the stoichiometric coefficient and is determined from the O_2 balance,

$$1.2a_{\text{th}} = 2 + 0.5 + 0.2a_{\text{th}} \longrightarrow a_{\text{th}} = 2.5$$

Substituting,

Under steady-flow conditions the exit temperature of the product gases can be determined from the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$

applied on the combustion chamber, which reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R \bar{h}_{f,R}^\circ = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - (N\bar{h}_f^\circ)_{\text{C}_2\text{H}_2}$$

since all the reactants are at the standard reference state, and $\bar{h}_f^\circ = 0$ for O_2 and N_2 . From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{ K}}$ kJ/kmol
$\text{C}_2\text{H}_2(g)$	226,730	---
O_2	0	8682
N_2	0	8669
$\text{H}_2\text{O}(g)$	-241,820	9904
CO_2	-393,520	9364

Substituting,

$$-300,000 = (2)(-393,520 + \bar{h}_{\text{CO}_2} - 9364) + (1)(-241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904) + (0.5)(0 + \bar{h}_{\text{O}_2} - 8682) + (11.28)(0 + \bar{h}_{\text{N}_2} - 8669) - (1)(226,730)$$

or,

$$2\bar{h}_{\text{CO}_2} + \bar{h}_{\text{H}_2\text{O}} + 0.5\bar{h}_{\text{O}_2} + 11.28\bar{h}_{\text{N}_2} = 1,086,349 \text{ kJ}$$

By trial and error,

$$T_P = \mathbf{2062.1 \text{ K}}$$

(b) The entropy generation during this process is determined from

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{out}}}{T_{\text{surr}}} = \sum N_P \bar{s}_P - \sum N_R \bar{s}_R + \frac{Q_{\text{out}}}{T_{\text{surr}}}$$

The C_2H_2 is at 25°C and 1 atm, and thus its absolute entropy is $\bar{s}_{\text{C}_2\text{H}_2} = 200.85 \text{ kJ/kmol}\cdot\text{K}$ (Table A-26). The entropy values listed in the ideal gas tables are for 1 atm pressure. Both the air and the product gases are at a total pressure of 1 atm, but the entropies are to be calculated at the partial pressure of the components which is equal to $P_i = y_i P_{\text{total}}$, where y_i is the mole fraction of component i . Also,

$$S_i = N_i \bar{s}_i(T, P_i) = N_i \left(\bar{s}_i^\circ(T, P_0) - R_u \ln(y_i P_m) \right)$$

The entropy calculations can be presented in tabular form as

	N_i	y_i	$\bar{s}_i^\circ(\mathbf{T}, 1\text{atm})$	$R_u \ln(y_i P_m)$	$N_i \bar{s}_i$
C_2H_2	1	1.00	200.85	---	200.85
O_2	3	0.21	205.03	-12.98	654.03
N_2	11.28	0.79	191.502	-1.96	2182.25
$S_R = 3037.13 \text{ kJ/K}$					
CO_2	2	0.1353	311.054	-16.630	655.37
H_2O	1	0.0677	266.139	-22.387	288.53
O_2	0.5	0.0338	269.810	-28.162	148.99
N_2	11.28	0.7632	253.068	-2.247	2879.95
$S_P = 3972.84 \text{ kJ/K}$					

Thus,

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{surr}}}{T_{\text{surr}}} = 3972.84 - 3037.13 + \frac{+300,000 \text{ kJ}}{298 \text{ K}} = \mathbf{1942.4 \text{ kJ/kmol} \cdot \mathbf{K}}$$

(c) The exergy destruction rate associated with this process is determined from

$$X_{\text{destruction}} = T_0 S_{\text{gen}} = (298 \text{ K})(1942.4 \text{ kJ/kmol} \cdot \text{K}) = \mathbf{578,835 \text{ kJ}} \text{ (per kmol } \text{C}_2\text{H}_2\text{)}$$

Review Problems

15-91 A sample of a certain fluid is burned in a bomb calorimeter. The heating value of the fuel is to be determined.

Properties The specific heat of water is $4.18 \text{ kJ/kg}\cdot^\circ\text{C}$ (Table A-3).

Analysis We take the water as the system, which is a closed system, for which the energy balance on the system

$E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ with $W = 0$ can be written as

$$Q_{\text{in}} = \Delta U$$

or

$$\begin{aligned} Q_{\text{in}} &= mc\Delta T \\ &= (2 \text{ kg})(4.18 \text{ kJ/kg}\cdot^\circ\text{C})(2.5^\circ\text{C}) \\ &= 20.90 \text{ kJ (per gram of fuel)} \end{aligned}$$

Therefore, heat transfer per kg of the fuel would be **20,900 kJ/kg fuel**. Disregarding the slight energy stored in the gases of the combustion chamber, this value corresponds to the heating value of the fuel.

15-92 The composition of a gaseous fuel is given. The fuel is burned with 120 percent theoretical air. The AF ratio and the volume flow rate of air intake are to be determined.

Assumptions 1 Combustion is complete. **2** Air and the combustion gases are ideal gases.

Properties The molar masses of C, H₂, N₂, O₂, and air are 12, 2, 28, 32, and 29 kg/kmol (Table A-1).

Analysis (a) The fuel is burned completely with excess air, and thus the products will contain H₂O, CO₂, N₂, and some free O₂. The moisture in the air does not react with anything; it simply shows up as additional H₂O in the products. Therefore, we can simply balance the combustion equation using dry air, and then add the moisture to both sides of the equation. Considering 1 kmol of fuel, the combustion equation can be written as

The unknown coefficients in the above equation are determined from mass balances,

$$\text{C: } 0.80 = x \longrightarrow x = 0.80$$

$$\text{H: } (0.80)(4) = 2y \longrightarrow y = 1.6$$

$$\text{O}_2: 0.05 + 1.2a_{\text{th}} = x + y/2 + 0.2a_{\text{th}} \longrightarrow a_{\text{th}} = 1.55$$

$$\text{N}_2: 0.15 + (1.2)(3.76)a_{\text{th}} = z \longrightarrow z = 7.14$$

Next we determine the amount of moisture that accompanies $4.76 \times 1.2a_{\text{th}} = 4.76 \times 1.2 \times 1.55 = 8.85$ kmol of dry air. The partial pressure of the moisture in the air is

$$P_{v,\text{in}} = \phi_{\text{air}} P_{\text{sat}@30^\circ\text{C}} = (0.60)(4.247 \text{ kPa}) = 2.548 \text{ kPa}$$

The number of moles of the moisture in the air ($N_{v,\text{in}}$) is determined to be

$$N_{v,\text{in}} = \left(\frac{P_{v,\text{in}}}{P_{\text{total}}} \right) N_{\text{total}} = \left(\frac{2.548 \text{ kPa}}{100 \text{ kPa}} \right) (8.85 + N_{v,\text{in}}) \longrightarrow N_{v,\text{in}} = 0.23 \text{ kmol}$$

The balanced combustion equation is obtained by substituting the coefficients determined earlier and adding 0.23 kmol of H₂O to both sides of the equation,

The air-fuel ratio for this reaction is determined by taking the ratio of the mass of the air to the mass of the fuel,

$$m_{\text{air}} = [(1.86)(4.76) \text{ kmol}](29 \text{ kg/kmol}) + (0.23 \text{ kg})(18 \text{ kg/kmol}) = 260.9 \text{ kg}$$

$$m_{\text{fuel}} = [(0.8)(16) + (0.15)(28) + (0.05)(32)] \text{ kg} = 18.6 \text{ kg}$$

and
$$\text{AF} = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{260.9 \text{ kg}}{18.6 \text{ kg}} = \mathbf{14.0 \text{ kg air/kg fuel}}$$

(b) The mass flow rate of the gaseous fuel is given to be 2 kg/min. Since we need 14.0 kg air per kg of fuel, the required mass flow rate of air is

$$\dot{m}_{\text{air}} = (\text{AF})(\dot{m}_{\text{fuel}}) = (14.0)(2 \text{ kg/min}) = 28.0 \text{ kg/min}$$

The mole fractions of water vapor and the dry air in the incoming air are

$$y_{\text{H}_2\text{O}} = \frac{N_{\text{H}_2\text{O}}}{N_{\text{total}}} = \frac{0.23}{8.85 + 0.23} = 0.025 \quad \text{and} \quad y_{\text{dry air}} = 1 - 0.025 = 0.975$$

Thus,

$$M = (yM)_{\text{H}_2\text{O}} + (yM)_{\text{dry air}} = (0.025)(18) + (0.975)(29) = 28.7 \text{ kg/kmol}$$

$$\nu = \frac{RT}{P} = \frac{(8.314/28.7 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(303 \text{ K})}{100 \text{ kPa}} = 0.878 \text{ m}^3/\text{kg}$$

$$\dot{V} = \dot{m} \nu = (28.0 \text{ kg/min})(0.878 \text{ m}^3/\text{kg}) = \mathbf{24.6 \text{ m}^3/\text{min}}$$

15-93E Hydrogen is burned with 100 percent excess air. The AF ratio and the volume flow rate of air are to be determined.

Assumptions 1 Combustion is complete. **2** Air and the combustion gases are ideal gases.

Properties The molar masses of H_2 and air are 2 kg/kmol and 29 kg/kmol, respectively (Table A-1).

Analysis (a) The combustion is complete, and thus products will contain only H_2O , O_2 and N_2 . The moisture in the air does not react with anything; it simply shows up as additional H_2O in the products. Therefore, for simplicity, we will balance the combustion equation using dry air, and then add the moisture to both sides of the equation. The combustion equation in this case can be written as

where a_{th} is the stoichiometric coefficient for air. It is determined from

$$O_2 \text{ balance: } 2a_{th} = 0.5 + a_{th} \longrightarrow a_{th} = 0.5$$

Substituting,

Therefore, 4.76 lbmol of dry air will be used per kmol of the fuel.

The partial pressure of the water vapor present in the incoming air is

$$P_{v,in} = \phi_{air} P_{sat@90^\circ F} = (0.60)(0.69904 \text{ psia}) = 0.419 \text{ psia}$$

The number of moles of the moisture that accompanies 4.76 lbmol of incoming dry air ($N_{v,in}$) is determined to be

$$N_{v,in} = \left(\frac{P_{v,in}}{P_{total}} \right) N_{total} = \left(\frac{0.419 \text{ psia}}{14.5 \text{ psia}} \right) (4.76 + N_{v,in}) \longrightarrow N_{v,in} = 0.142 \text{ lbmol}$$

The balanced combustion equation is obtained by substituting the coefficients determined earlier and adding 0.142 lbmol of H_2O to both sides of the equation,

The air-fuel ratio is determined by taking the ratio of the mass of the air to the mass of the fuel,

$$AF = \frac{m_{air}}{m_{fuel}} = \frac{(4.76 \text{ lbmol})(29 \text{ lbm/lbmol}) + (0.142 \text{ lbmol})(18 \text{ lbm/lbmol})}{(1 \text{ lbmol})(2 \text{ lbm/lbmol})} = \mathbf{70.3 \text{ lbm air/lbm fuel}}$$

(b) The mass flow rate of H_2 is given to be 10 lbm/h. Since we need 70.3 lbm air per lbm of H_2 , the required mass flow rate of air is

$$\dot{m}_{air} = (AF)(\dot{m}_{fuel}) = (70.3)(40 \text{ lbm/h}) = 2812 \text{ lbm/h}$$

The mole fractions of water vapor and the dry air in the incoming air are

$$y_{H_2O} = \frac{N_{H_2O}}{N_{total}} = \frac{0.142}{4.76 + 0.142} = 0.029 \quad \text{and} \quad y_{dryair} = 1 - 0.029 = 0.971$$

Thus,

$$M = (yM)_{H_2O} + (yM)_{dryair} = (0.029)(18) + (0.971)(29) = 28.7 \text{ lbm/lbmol}$$

$$\nu = \frac{RT}{P} = \frac{(10.73/28.7 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(540 \text{ R})}{14.5 \text{ psia}} = 13.92 \text{ ft}^3/\text{lbm}$$

$$\dot{V} = \dot{m} \nu = (2812 \text{ lbm/h})(13.92 \text{ ft}^3/\text{lbm}) = \mathbf{39,140 \text{ ft}^3/\text{h}}$$

15-94E Propane is burned with stoichiometric amount of air. The fraction of the water in the products that is vapor is to be determined.

Assumptions **1** Combustion is complete. **2** Steady operating conditions exist. **3** Air and the combustion gases are ideal gases.

Analysis The fuel is burned completely with the air, and thus the products will contain only CO_2 , H_2O , and N_2 . Considering 1 kmol C_3H_8 , the combustion equation can be written as

The mole fraction of water in the products is

$$y = \frac{N_{\text{H}_2\text{O}}}{N_{\text{prod}}} = \frac{4 \text{ kmol}}{(3 + 4 + 18.8)\text{kmol}} = 0.1550$$

The saturation pressure for the water vapor is

$$P_v = P_{\text{sat}@120^\circ\text{F}} = 1.6951 \text{ psia}$$

When the combustion gases are saturated, the mole fraction of the water vapor will be

$$y_g = \frac{P_v}{P} = \frac{1.6951 \text{ kPa}}{14.696 \text{ kPa}} = 0.1153$$

Thus, the fraction of water vapor in the combustion products is

$$f_{\text{vapor}} = \frac{y_g}{y} = \frac{0.1153}{0.1550} = \mathbf{0.744}$$

15-95 Coal whose mass percentages are specified is burned with 20% excess air. The dew-point temperature of the products is to be determined.

Assumptions 1 Combustion is complete. **2** The combustion products contain CO_2 , CO , H_2O , SO_2 , and N_2 . **3** Combustion gases are ideal gases.

Properties The molar masses of C, H_2 , O_2 , S, and air are 12, 2, 32, 32, and 29 kg/kmol, respectively (Table A-1).

Analysis We consider 100 kg of coal for simplicity. Noting that the mass percentages in this case correspond to the masses of the constituents, the mole numbers of the constituent of the coal are determined to be

$$N_{\text{C}} = \frac{m_{\text{C}}}{M_{\text{C}}} = \frac{61.40 \text{ kg}}{12 \text{ kg/kmol}} = 5.117 \text{ kmol}$$

$$N_{\text{H}_2} = \frac{m_{\text{H}_2}}{M_{\text{H}_2}} = \frac{5.79 \text{ kg}}{2 \text{ kg/kmol}} = 2.895 \text{ kmol}$$

$$N_{\text{O}_2} = \frac{m_{\text{O}_2}}{M_{\text{O}_2}} = \frac{25.31 \text{ kg}}{32 \text{ kg/kmol}} = 0.7909 \text{ kmol}$$

$$N_{\text{N}_2} = \frac{m_{\text{N}_2}}{M_{\text{N}_2}} = \frac{1.09 \text{ kg}}{28 \text{ kg/kmol}} = 0.03893 \text{ kmol}$$

$$N_{\text{S}} = \frac{m_{\text{S}}}{M_{\text{S}}} = \frac{1.41 \text{ kg}}{32 \text{ kg/kmol}} = 0.04406 \text{ kmol}$$

61.40% C
5.79% H_2
25.31% O_2
1.09% N_2
1.41% S
5.00% ash
(by mass)

The mole number of the mixture and the mole fractions are

$$N_m = 5.117 + 2.895 + 0.7909 + 0.03893 + 0.04406 = 8.886 \text{ kmol}$$

$$y_{\text{C}} = \frac{N_{\text{C}}}{N_m} = \frac{5.117 \text{ kmol}}{8.886 \text{ kmol}} = 0.5758$$

$$y_{\text{H}_2} = \frac{N_{\text{H}_2}}{N_m} = \frac{2.895 \text{ kmol}}{8.886 \text{ kmol}} = 0.3258$$

$$y_{\text{O}_2} = \frac{N_{\text{O}_2}}{N_m} = \frac{0.7909 \text{ kmol}}{8.886 \text{ kmol}} = 0.0890$$

$$y_{\text{N}_2} = \frac{N_{\text{N}_2}}{N_m} = \frac{0.03893 \text{ kmol}}{8.886 \text{ kmol}} = 0.00438$$

$$y_{\text{S}} = \frac{N_{\text{S}}}{N_m} = \frac{0.04406 \text{ kmol}}{8.886 \text{ kmol}} = 0.00496$$

Ash consists of the non-combustible matter in coal. Therefore, the mass of ash content that enters the combustion chamber is equal to the mass content that leaves. Disregarding this non-reacting component for simplicity, the combustion equation may be written as

According to the oxygen balance,

$$\text{O}_2 \text{ balance : } 0.0890 + 1.25a_{\text{th}} = 0.5758 + 0.5 \times 0.3258 + 0.00496 + 0.25a_{\text{th}} \longrightarrow a_{\text{th}} = 0.6547$$

Substituting,

The dew-point temperature of a gas-vapor mixture is the saturation temperature of the water vapor in the product gases corresponding to its partial pressure. That is,

$$P_v = \left(\frac{N_v}{N_{\text{prod}}} \right) P_{\text{prod}} = \left(\frac{0.3258 \text{ kmol}}{(0.5758 + 0.3258 + 0.00496 + 0.1637 + 3.077) \text{ kmol}} \right) (101.3 \text{ kPa}) = 7.96 \text{ kPa}$$

Thus, $T_{\text{dp}} = T_{\text{sat}@7.96 \text{ kPa}} = \mathbf{41.3^\circ\text{C}}$ (Table A-5)

15-96 Methane is burned steadily with 15 percent excess air. The dew-point temperature of the water vapor in the products is to be determined.

Assumptions 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases.

Properties The molar masses of CH_4 and air are 16 kg/kmol and 29 kg/kmol, respectively (Table A-1).

Analysis The fuel is burned completely with the excess air, and thus the products will contain only CO_2 , H_2O , N_2 , and some free O_2 . Considering 1 kmol CH_4 , the combustion equation can be written as

where a_{th} is the stoichiometric coefficient and is determined from the O_2 balance,

$$1.15a_{\text{th}} = 1 + 1 + 0.15a_{\text{th}} \longrightarrow a_{\text{th}} = 2$$

Thus,

The dew-point temperature of a gas-vapor mixture is the saturation temperature of the water vapor in the product gases corresponding to its partial pressure. That is,

$$P_v = \left(\frac{N_v}{N_{\text{prod}}} \right) P_{\text{prod}} = \left(\frac{2 \text{ kmol}}{(1 + 2 + 0.3 + 8.648) \text{ kmol}} \right) (101.325 \text{ kPa}) = 16.96 \text{ kPa}$$

Thus,

$$T_{\text{dp}} = T_{\text{sat}@16.96 \text{ kPa}} = \mathbf{56.5^\circ\text{C}} \quad (\text{EES or Table A-5})$$

15-97 A mixture of 40% by volume methane, CH₄, and 60% by volume propane, C₃H₈, is burned completely with theoretical air. The amount of water formed during combustion process that will be condensed is to be determined.

Assumptions 1 Combustion is complete. **2** The combustion products contain CO₂, H₂O, and N₂ only.

Properties The molar masses of C, H₂, O₂ and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis The combustion equation in this case can be written as

where a_{th} is the stoichiometric coefficient for air. The coefficient a_{th} and other coefficients are to be determined from the mass balances

Carbon balance: $B = 0.4 + 3 \times 0.6 = 2.2$

Hydrogen balance: $2D = 4 \times 0.4 + 8 \times 0.6 = 2D \longrightarrow D = 3.2$

Oxygen balance: $2a_{\text{th}} = 2B + D \longrightarrow 2a_{\text{th}} = 2(2.2) + 3.2 \longrightarrow a_{\text{th}} = 3.8$

Nitrogen balance: $3.76a_{\text{th}} = F \longrightarrow 3.76(3.8) = F \longrightarrow F = 14.29$

Then, we write the balanced reaction equation as

The vapor mole fraction in the products is

$$y_v = \frac{3.2}{2.2 + 3.2 + 14.29} = 0.1625$$

The partial pressure of water in the products is

$$P_{v,\text{prod}} = y_v P_{\text{prod}} = (0.1625)(100 \text{ kPa}) = 16.25 \text{ kPa}$$

The dew point temperature of the products is

$$T_{\text{dp}} = T_{\text{sat}@16.25\text{kPa}} = 55.64^\circ\text{C}$$

The partial pressure of the water vapor remaining in the products at the product temperature is

$$P_v = P_{\text{sat}@39^\circ\text{C}} = 7.0 \text{ kPa}$$

The kmol of water vapor in the products at the product temperature is

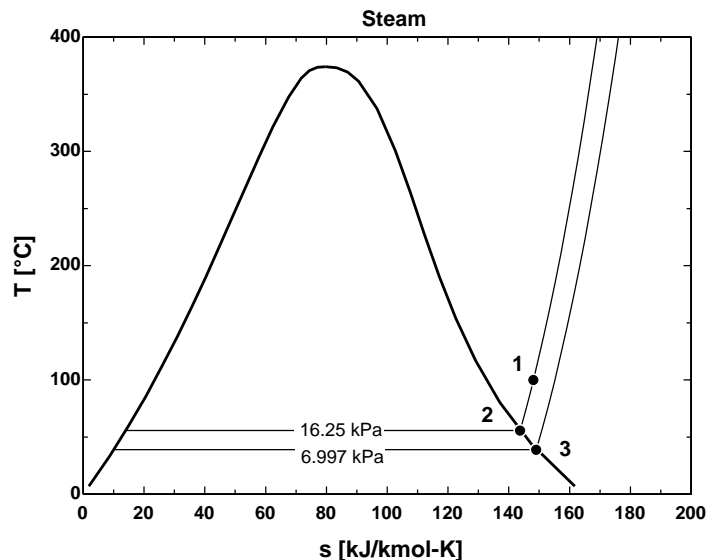

$$P_v = \frac{N_v}{N_{\text{total,product}}} P_{\text{prod}}$$

$$7.0 \text{ kPa} = \frac{N_v}{2.2 + N_v + 14.29} (100 \text{ kPa})$$

$$N_v = 1.241 \text{ kmol}$$

The kmol of water condensed is

$$N_w = 3.2 - 1.241 = \mathbf{1.96 \text{ kmol water/kmol fuel}}$$

15-98 A gaseous fuel mixture of 60% propane, C_3H_8 , and 40% butane, C_4H_{10} , on a volume basis is burned with an air-fuel ratio of 19. The moles of nitrogen in the air supplied to the combustion process, the moles of water formed in the combustion process, and the moles of oxygen in the product gases are to be determined.

Assumptions 1 Combustion is complete. **2** The combustion products contain CO_2 , H_2O , and N_2 only.

Properties The molar masses of C, H_2 , O_2 and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis The theoretical combustion equation in this case can be written as

where a_{th} is the stoichiometric coefficient for air. The coefficient a_{th} and other coefficients are to be determined from the mass balances

$$\text{Carbon balance:} \quad B = 3 \times 0.6 + 4 \times 0.4 = 3.4$$

$$\text{Hydrogen balance:} \quad 8 \times 0.6 + 10 \times 0.4 = 2D \longrightarrow D = 4.4$$

$$\text{Oxygen balance:} \quad 2a_{th} = 2B + D \longrightarrow 2a_{th} = 2 \times 3.4 + 4.4 \longrightarrow a_{th} = 5.6$$

$$\text{Nitrogen balance:} \quad 3.76a_{th} = F \longrightarrow 3.76 \times 5.6 = F \longrightarrow F = 21.06$$

Then, we write the balanced theoretical reaction equation as

The air-fuel ratio for the theoretical reaction is determined from

$$AF_{th} = \frac{m_{air}}{m_{fuel}} = \frac{(5.6 \times 4.76 \text{ kmol})(29 \text{ kg/kmol})}{(0.6 \times 44 + 0.4 \times 58) \text{ kg}} = 15.59 \text{ kg air/kg fuel}$$

The percent theoretical air is

$$\text{PercentTH}_{air} = \frac{AF_{actual}}{AF_{th}} = \frac{19}{15.59} \times 100 = 121.9\%$$

The moles of nitrogen supplied is

$$N_{N_2} = \frac{\text{PercentTH}_{air}}{100} \times a_{th} \times 3.76 = \frac{121.9}{100} (5.6)(3.76) = \mathbf{25.7 \text{ kmol}} \text{ per kmol fuel}$$

The moles of water formed in the combustion process is

$$N_{H_2O} = D = \mathbf{4.4 \text{ kmol}} \text{ per kmol fuel}$$

The moles of oxygen in the product gases is

$$N_{O_2} = \left(\frac{\text{PercentTH}_{air}}{100} - 1 \right) a_{th} = \left(\frac{121.9}{100} - 1 \right) (5.6) = \mathbf{1.23 \text{ kmol}} \text{ per kmol fuel}$$

15-99 A liquid gas fuel mixture consisting of 90% octane, C_8H_{18} , and 10% alcohol, C_2H_5OH , by moles is burned with 200% theoretical dry air. The balanced reaction equation for complete combustion of this fuel mixture is to be written, and the theoretical air-fuel ratio and the product-fuel ratio for this reaction, and the lower heating value of the fuel mixture with 200% theoretical air are to be determined.

Assumptions 1 Combustion is complete. **2** The combustion products contain CO_2 , H_2O , O_2 , and N_2 only.

Properties The molar masses of C, H_2 , O_2 , N_2 , and air are 12, 2, 32, 28, and 29 kg/kmol, respectively (Table A-1).

Analysis The reaction equation for 100% excess air is

where a_{th} is the stoichiometric coefficient for air. We have automatically accounted for the 100% excess air by using the factor $2a_{\text{th}}$ instead of a_{th} for air. The coefficient a_{th} and other coefficients are to be determined from the mass balances

Carbon balance: $8 \times 0.9 + 2 \times 0.1 = B \longrightarrow B = 7.4$

Hydrogen balance: $18 \times 0.9 + 6 \times 0.1 = 2D \longrightarrow D = 8.4$

Oxygen balance: $0.1 \times 1 + 2 \times 2a_{\text{th}} = 2B + D + 2E$

$$a_{\text{th}} = E$$

Nitrogen balance: $2a_{\text{th}} \times 3.76 = F$

Solving the above equations, we find the coefficients ($E = 11.55$, $F = 86.86$, and $a_{\text{th}} = 11.55$) and write the balanced reaction equation as

The theoretical air-fuel ratio is determined by taking the ratio of the mass of the air to the mass of the fuel for the theoretical reaction,

$$\begin{aligned} AF_{\text{th}} &= \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{a_{\text{th}} \times 4.76 \times M_{\text{air}}}{0.9 \times M_{C_8H_{18}} + 0.1 \times M_{C_2H_5OH}} \\ &= \frac{(11.55 \times 4.76 \text{ kmol})(29 \text{ kg/kmol})}{(0.9 \times 114 + 0.1 \times 46) \text{ kg}} \\ &= \mathbf{14.83 \text{ kg air/kg fuel}} \end{aligned}$$

The actual air-fuel ratio is

$$AF_{\text{actual}} = 2AF_{\text{th}} = 2(14.83) = 29.65 \text{ kg air/kg fuel}$$

Then, the mass flow rate of air becomes

$$\dot{m}_{\text{air}} = AF_{\text{actual}} \dot{m}_{\text{fuel}} = (29.65)(5 \text{ kg/s}) = \mathbf{148.3 \text{ kg/s}}$$

The molar mass of the product gases is determined from

$$\begin{aligned} M_{\text{prod}} &= \frac{N_{CO_2}M_{CO_2} + N_{H_2O}M_{H_2O} + N_{O_2}M_{O_2} + N_{N_2}M_{N_2}}{N_{CO_2} + N_{H_2O} + N_{O_2} + N_{N_2}} \\ &= \frac{7.4(44) + 8.4(18) + 11.55(32) + 86.86(28)}{7.4 + 8.4 + 11.55 + 86.86} \\ &= 28.72 \text{ kg/kmol} \end{aligned}$$

The mass of product gases per unit mass of fuel is

$$\begin{aligned} m_{\text{prod}} &= \frac{(N_{CO_2} + N_{H_2O} + N_{O_2} + N_{N_2})M_{\text{prod}}}{0.9 \times M_{C_8H_{18}} + 0.1 \times M_{C_2H_5OH}} \\ &= \frac{(7.4 + 8.4 + 11.55 + 86.86)(28.72 \text{ kg/kmol})}{(0.9 \times 114 + 0.1 \times 46) \text{ kg}} \\ &= \mathbf{30.54 \text{ kg product/kg fuel}} \end{aligned}$$

The steady-flow energy balance can be expressed as

$$H_R = \bar{q}_{\text{LHV}} + H_P$$

where

$$\begin{aligned} H_R &= 0.9(\bar{h}_{\text{C}_8\text{H}_{18}@25^\circ\text{C}} - \bar{h}_{f_g,\text{C}_8\text{H}_{18}}) + 0.1(\bar{h}_{\text{C}_2\text{H}_5\text{OH}@25^\circ\text{C}} - \bar{h}_{f_g,\text{C}_2\text{H}_5\text{OH}}) + 23.1\bar{h}_{\text{O}_2@25^\circ\text{C}} + 86.86\bar{h}_{\text{N}_2@25^\circ\text{C}} \\ &= 0.9(-208,459 - 41,465) + 0.1(-235,310 - 42,340) + 23.1(0) + 86.86(0) \\ &= -252,697 \text{ kJ/kmol} \end{aligned}$$

$$\begin{aligned} H_P &= 7.4\bar{h}_{\text{CO}_2@25^\circ\text{C}} + 8.4\bar{h}_{\text{H}_2\text{O}@25^\circ\text{C}} + 11.55\bar{h}_{\text{N}_2@25^\circ\text{C}} + 86.86\bar{h}_{\text{N}_2@25^\circ\text{C}} \\ &= 7.4(-393,520) + 8.4(-241,820) + 11.55(0) + 86.86(0) \\ &= -4.943 \times 10^6 \text{ kJ/kmol} \end{aligned}$$

Substituting, we obtain

$$\bar{q}_{\text{LHV}} = 4.691 \times 10^6 \text{ kJ/kmol}$$

The lower heating value on a mass basis is determined to be

$$\begin{aligned} q_{\text{LHV}} &= \frac{\bar{q}_{\text{LHV}}}{0.9 \times M_{\text{C}_8\text{H}_{18}} + 0.1 \times M_{\text{C}_2\text{H}_5\text{OH}}} \\ &= \frac{4.691 \times 10^6 \text{ kJ/kmol}}{(0.9 \times 114 + 0.1 \times 46) \text{ kg/kmol}} \\ &= \mathbf{43,760 \text{ kJ/kg}} \end{aligned}$$

15-100 CO gas is burned with air during a steady-flow combustion process. The rate of heat transfer from the combustion chamber is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 There are no work interactions. 5 Combustion is complete.

Properties The molar masses of CO and air are 28 kg/kmol and 29 kg/kmol, respectively (Table A-1).

Analysis We first need to calculate the amount of air used per kmol of CO before we can write the combustion equation,

$$\nu_{\text{CO}} = \frac{RT}{P} = \frac{(0.2968 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(310 \text{ K})}{(110 \text{ kPa})} = 0.836 \text{ m}^3/\text{kg}$$

$$\dot{m}_{\text{CO}} = \frac{\dot{V}_{\text{CO}}}{\nu_{\text{CO}}} = \frac{0.4 \text{ m}^3/\text{min}}{0.836 \text{ m}^3/\text{kg}} = 0.478 \text{ kg/min}$$

Then the molar air-fuel ratio becomes

$$\overline{\text{AF}} = \frac{N_{\text{air}}}{N_{\text{fuel}}} = \frac{\dot{m}_{\text{air}} / M_{\text{air}}}{\dot{m}_{\text{fuel}} / M_{\text{fuel}}} = \frac{(1.5 \text{ kg/min}) / (29 \text{ kg/kmol})}{(0.478 \text{ kg/min}) / (28 \text{ kg/kmol})} = 3.03 \text{ kmol air/kmol fuel}$$

Thus the number of moles of O_2 used per mole of CO is $3.03/4.76 = 0.637$. Then the combustion equation in this case can be written as

Under steady-flow conditions the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $W = 0$ reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298 \text{ K}}$ kJ/kmol	$\bar{h}_{310 \text{ K}}$ kJ/kmol	$\bar{h}_{900 \text{ K}}$ kJ/kmol
CO	-110,530	8669	9014	27,066
O_2	0	8682	---	27,928
N_2	0	8669	---	26,890
CO_2	-393,520	9364	---	37,405

Thus,

$$\begin{aligned} -Q_{\text{out}} &= (1)(-393,520 + 37,405 - 9364) + (0.137)(0 + 27,928 - 8682) \\ &\quad + (2.4)(0 + 26,890 - 8669) - (1)(-110,530 + 9014 - 8669) - 0 - 0 \\ &= -208,927 \text{ kJ/kmol of CO} \end{aligned}$$

Then the rate of heat transfer for a mass flow rate of 0.956 kg/min for CO becomes

$$\dot{Q}_{\text{out}} = \dot{N} Q_{\text{out}} = \left(\frac{\dot{m}}{M} \right) Q_{\text{out}} = \left(\frac{0.478 \text{ kg/min}}{28 \text{ kg/kmol}} \right) (208,927 \text{ kJ/kmol}) = \mathbf{3567 \text{ kJ/min}}$$

15-101 A mixture of hydrogen and the stoichiometric amount of air contained in a rigid tank is ignited. The fraction of H₂O that condenses and the heat transfer from the combustion chamber are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible. 4 There are no work interactions. 5 Combustion is complete.

Analysis The theoretical combustion equation of H₂ with stoichiometric amount of air is

where a_{th} is the stoichiometric coefficient and is determined from the O₂ balance,

$$a_{\text{th}} = 0.5$$

Thus,

(a) At 25°C part of the water (say, N_w moles) will condense, and the number of moles of products that remains in the gas phase will be $2.88 - N_w$. Neglecting the volume occupied by the liquid water and treating all the product gases as ideal gases, the final pressure in the tank can be expressed as

$$P_f = \frac{N_{f,\text{gas}} R_u T_f}{V} = \frac{(2.88 - N_w \text{ kmol})(8.314 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(298 \text{ K})}{6 \text{ m}^3} = 412.9(2.88 - N_w) \text{ kPa}$$

Then,

$$\frac{N_v}{N_{\text{gas}}} = \frac{P_v}{P_{\text{total}}} \longrightarrow \frac{1 - N_w}{2.88 - N_w} = \frac{3.169 \text{ kPa}}{412.9(2.88 - N_w) \text{ kPa}} \longrightarrow N_w = 0.992 \text{ kmol}$$

Thus **99.2%** of the H₂O will condense when the products are cooled to 25°C.

(b) The energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied for this constant volume combustion process with $W = 0$ reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_R$$

With the exception of liquid water for which the $P\bar{v}$ term is negligible, both the reactants and the products are assumed to be ideal gases, all the internal energy and enthalpies depend on temperature only, and the $P\bar{v}$ terms in this equation can be replaced by $R_u T$. It yields

$$\begin{aligned} -Q_{\text{out}} &= \sum N_P (\bar{h}_f^\circ - R_u T)_P - \sum N_R (\bar{h}_f^\circ - R_u T)_R \\ &= \sum N_P \bar{h}_{f,P}^\circ - \sum N_R \bar{h}_{f,R}^\circ - R_u T (\sum N_{P,\text{gas}} - \sum N_R) \end{aligned}$$

since the reactants are at the standard reference temperature of 25°C. From the tables,

Substance	\bar{h}_f° kJ/kmol
H ₂	0
O ₂	0
N ₂	0
H ₂ O (g)	-241,820
H ₂ O (ℓ)	-285,830

Thus,

$$\begin{aligned} -Q_{\text{out}} &= (0.008)(-241,820) + (0.992)(-285,830) + 0 - 0 - 0 - 0 - 8.314 \times 298(1.89 - 3.38) \\ &= -281,786 \text{ kJ (per kmol H}_2) \end{aligned}$$

or $Q_{\text{out}} = \mathbf{281,786 \text{ kJ}}$ (per kmol H₂)

15-102 Ethanol gas is burned with 10% excess air. The combustion is incomplete. The theoretical kmols of oxygen in the reactants, the balanced chemical reaction, and the rate of heat transfer are to be determined.

Assumptions 1 Combustion is incomplete. 2 The combustion products contain CO_2 , CO , H_2O , O_2 , and N_2 only.

Properties The molar masses of C, H_2 , O_2 , N_2 and air are 12 kg/kmol, 2 kg/kmol, 32 kg/kmol, 28 kg/kmol, and 29 kg/kmol, respectively (Table A-1).

Analysis (a) The balanced reaction equation for stoichiometric air is

The stoichiometric coefficient a_{th} is determined from an O_2 balance:

$$0.5 + a_{\text{th}} = 2 + 1.5 \longrightarrow a_{\text{th}} = 3$$

Substituting,

Therefore, **3 kmol of oxygen** is required to burn 1 kmol of ethanol.

(b) The reaction with 10% excess air and incomplete combustion can be written as

The coefficient for O_2 is determined from a mass balance,

$$\text{O}_2 \text{ balance: } 0.5 + 1.1 \times 3 = 0.9 \times 2 + 0.5 \times (0.1 \times 2) + 0.5 \times 3 + x \longrightarrow x = 0.4$$

Substituting,

(b) The heat transfer for this combustion process is determined from the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $W = 0$. It reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Both the reactants and products are at 25°C . Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. Then, using the values given in the table,

$$\begin{aligned} -Q_{\text{out}} &= (1.8)(-393,520) + (0.2)(-110,530) + (3)(-241,820) - (1)(-235,310) \\ &= -1,220,590 \text{ kJ/kmol fuel} \end{aligned}$$

or

$$Q_{\text{out}} = 1,220,590 \text{ kJ/kmol fuel}$$

For a 3.5 kg/h of fuel burned, the rate of heat transfer is

$$\dot{Q}_{\text{out}} = \dot{N} Q_{\text{out}} = \left(\frac{\dot{m}}{M} \right) Q_{\text{out}} = \frac{3.5 \text{ kg/h}}{46 \text{ kg/kmol}} (1,220,590 \text{ kJ/kmol}) = 92,870 \text{ kJ/h} = \mathbf{25.80 \text{ kW}}$$

15-103 Propane gas is burned with air during a steady-flow combustion process. The adiabatic flame temperature is to be determined for different cases.

Assumptions 1 Steady operating conditions exist. **2** Air and combustion gases are ideal gases. **3** Kinetic and potential energies are negligible. **4** There are no work interactions. **5** The combustion chamber is adiabatic.

Analysis Adiabatic flame temperature is the temperature at which the products leave the combustion chamber under adiabatic conditions ($Q = 0$) with no work interactions ($W = 0$). Under steady-flow conditions the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber reduces to

$$\sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P = \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R \longrightarrow \sum N_P (\bar{h}_f^\circ + \bar{h}_T - \bar{h}^\circ)_P = (N \bar{h}_f^\circ)_{\text{C}_3\text{H}_8}$$

since all the reactants are at the standard reference temperature of 25°C, and $\bar{h}_f^\circ = 0$ for O₂ and N₂.

(a) The theoretical combustion equation of C₃H₈ with stoichiometric amount of air is

From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{ K}}$ kJ/kmol
C ₃ H ₈ (g)	-103,850	---
O ₂	0	8682
N ₂	0	8669
H ₂ O (g)	-241,820	9904
CO	-110,530	8669
CO ₂	-393,520	9364

Thus,

$$(3)(-393,520 + \bar{h}_{\text{CO}_2} - 9364) + (4)(-241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904) + (18.8)(0 + \bar{h}_{\text{N}_2} - 8669) = (1)(-103,850)$$

It yields

$$3\bar{h}_{\text{CO}_2} + 4\bar{h}_{\text{H}_2\text{O}} + 18.8\bar{h}_{\text{N}_2} = 2,274,675 \text{ kJ}$$

The adiabatic flame temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields $2,274,675 / (3 + 4 + 18.8) = 88,165$ kJ/kmol. This enthalpy value corresponds to about 2650 K for N₂. Noting that the majority of the moles are N₂, T_P will be close to 2650 K, but somewhat under it because of the higher specific heats of CO₂ and H₂O.

$$\begin{aligned} \text{At 2400 K: } 3\bar{h}_{\text{CO}_2} + 4\bar{h}_{\text{H}_2\text{O}} + 18.8\bar{h}_{\text{N}_2} &= (3)(125,152) + (4)(103,508) + (18.8)(79,320) \\ &= 2,280,704 \text{ kJ (Higher than 2,274,675 kJ)} \end{aligned}$$

$$\begin{aligned} \text{At 2350 K: } 3\bar{h}_{\text{CO}_2} + 4\bar{h}_{\text{H}_2\text{O}} + 18.8\bar{h}_{\text{N}_2} &= (3)(122,091) + (4)(100,846) + (18.8)(77,496) \\ &= 2,226,582 \text{ kJ (Lower than 2,274,675 kJ)} \end{aligned}$$

By interpolation, $T_P = \mathbf{2394 \text{ K}}$

(b) The balanced combustion equation for complete combustion with 200% theoretical air is

Substituting known numerical values,

$$(3)(-393,520 + \bar{h}_{\text{CO}_2} - 9364) + (4)(-241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904) \\ + (5)(0 + \bar{h}_{\text{O}_2} - 8682) + (37.6)(0 + \bar{h}_{\text{N}_2} - 8669) = (1)(-103,850)$$

which yields

$$3\bar{h}_{\text{CO}_2} + 4\bar{h}_{\text{H}_2\text{O}} + 5\bar{h}_{\text{O}_2} + 37.6\bar{h}_{\text{N}_2} = 2,481,060 \text{ kJ}$$

The adiabatic flame temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields $2,481,060 / (3 + 4 + 5 + 37.6) = 50,021 \text{ kJ/kmol}$. This enthalpy value corresponds to about 1580 K for N_2 . Noting that the majority of the moles are N_2 , T_P will be close to 1580 K, but somewhat under it because of the higher specific heats of CO_2 and H_2O .

$$\text{At 1540 K: } 3\bar{h}_{\text{CO}_2} + 4\bar{h}_{\text{H}_2\text{O}} + 5\bar{h}_{\text{O}_2} + 37.6\bar{h}_{\text{N}_2} = (3)(73,417) + (4)(59,888) + (5)(50,756) + (37.6)(48,470) \\ = 2,536,055 \text{ kJ (Higher than 2,481,060 kJ)}$$

$$\text{At 1500 K: } 3\bar{h}_{\text{CO}_2} + 4\bar{h}_{\text{H}_2\text{O}} + 5\bar{h}_{\text{O}_2} + 37.6\bar{h}_{\text{N}_2} = (3)(71,078) + (4)(57,999) + (5)(49,292) + (37.6)(47,073) \\ = 2,461,630 \text{ kJ (Lower than 2,481,060 kJ)}$$

By interpolation, $T_P = \mathbf{1510 \text{ K}}$

(c) The balanced combustion equation for incomplete combustion with 90% theoretical air is

Substituting known numerical values,

$$(2)(-393,520 + \bar{h}_{\text{CO}_2} - 9364) + (1)(-110,530 + \bar{h}_{\text{CO}} - 8669) \\ + (4)(-241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904) + (16.92)(0 + \bar{h}_{\text{N}_2} - 8669) = (1)(-103,850)$$

which yields

$$2\bar{h}_{\text{CO}_2} + \bar{h}_{\text{CO}} + 4\bar{h}_{\text{H}_2\text{O}} + 16.92\bar{h}_{\text{N}_2} = 1,974,692 \text{ kJ}$$

The adiabatic flame temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields $1,974,692 / (2 + 1 + 4 + 16.92) = 82,554 \text{ kJ/kmol}$. This enthalpy value corresponds to about 2500 K for N_2 . Noting that the majority of the moles are N_2 , T_P will be close to 2500 K, but somewhat under it because of the higher specific heats of CO_2 and H_2O .

At 2250 K:

$$2\bar{h}_{\text{CO}_2} + \bar{h}_{\text{CO}} + 4\bar{h}_{\text{H}_2\text{O}} + 16.92\bar{h}_{\text{N}_2} = (2)(115,984) + (1)(74,516) + (4)(95,562) + (16.92)(73,856) \\ = 1,938,376 \text{ kJ (Higher than 1,974,692 kJ)}$$

At 2300 K:

$$2\bar{h}_{\text{CO}_2} + \bar{h}_{\text{CO}} + 4\bar{h}_{\text{H}_2\text{O}} + 16.92\bar{h}_{\text{N}_2} = (2)(119,035) + (1)(76,345) + (4)(98,199) + (16.92)(75,676) \\ = 1,987,649 \text{ kJ (Lower than 1,974,692 kJ)}$$

By interpolation, $T_P = \mathbf{2287 \text{ K}}$

15-104 The highest possible temperatures that can be obtained when liquid gasoline is burned steadily with air and with pure oxygen are to be determined.

Assumptions 1 Steady operating conditions exist. **2** Air and combustion gases are ideal gases. **3** Kinetic and potential energies are negligible. **4** There are no work interactions. **5** The combustion chamber is adiabatic.

Analysis The highest possible temperature that can be achieved during a combustion process is the temperature which occurs when a fuel is burned completely with stoichiometric amount of air in an adiabatic combustion chamber. It is determined from

$$\sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P = \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R \longrightarrow \sum N_P (\bar{h}_f^\circ + \bar{h}_T - \bar{h}^\circ)_P = (N\bar{h}_f^\circ)_{C_8H_{18}}$$

since all the reactants are at the standard reference temperature of 25°C, and for O₂ and N₂. The theoretical combustion equation of C₈H₁₈ air is

From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{ K}}$ kJ/kmol
C ₈ H ₁₈ (ℓ)	-249,950	---
O ₂	0	8682
N ₂	0	8669
H ₂ O (g)	-241,820	9904
CO ₂	-393,520	9364

Thus,

$$(8)(-393,520 + \bar{h}_{CO_2} - 9364) + (9)(-241,820 + \bar{h}_{H_2O} - 9904) + (47)(0 + \bar{h}_{N_2} - 8669) = (1)(-249,950)$$

It yields $8\bar{h}_{CO_2} + 9\bar{h}_{H_2O} + 47\bar{h}_{N_2} = 5,646,081$ kJ

The adiabatic flame temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields $5,646,081/(8 + 9 + 47) = 88,220$ kJ/kmol. This enthalpy value corresponds to about 2650 K for N₂. Noting that the majority of the moles are N₂, T_P will be close to 2650 K, but somewhat under it because of the higher specific heat of H₂O.

$$\begin{aligned} \text{At 2400 K: } 8\bar{h}_{CO_2} + 9\bar{h}_{H_2O} + 47\bar{h}_{N_2} &= (8)(125,152) + (9)(103,508) + (47)(79,320) \\ &= 5,660,828 \text{ kJ (Higher than 5,646,081 kJ)} \end{aligned}$$

$$\begin{aligned} \text{At 2350 K: } 8\bar{h}_{CO_2} + 9\bar{h}_{H_2O} + 47\bar{h}_{N_2} &= (8)(122,091) + (9)(100,846) + (47)(77,496) \\ &= 5,526,654 \text{ kJ (Lower than 5,646,081 kJ)} \end{aligned}$$

By interpolation, $T_P = 2395$ K

If the fuel is burned with stoichiometric amount of pure O₂, the combustion equation would be

$$\text{Thus, } (8)(-393,520 + \bar{h}_{CO_2} - 9364) + (9)(-241,820 + \bar{h}_{H_2O} - 9904) = (1)(-249,950)$$

It yields $8\bar{h}_{CO_2} + 9\bar{h}_{H_2O} = 5,238,638$ kJ

The adiabatic flame temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields $5,238,638/(8 + 9) = 308,155$ kJ/kmol. This enthalpy value is higher than the highest enthalpy value listed for H₂O and CO₂. Thus an estimate of the adiabatic flame temperature can be obtained by extrapolation.

$$\text{At 3200 K: } 8\bar{h}_{CO_2} + 9\bar{h}_{H_2O} = (8)(174,695) + (9)(147,457) = 2,724,673 \text{ kJ}$$

$$\text{At 3250 K: } 8\bar{h}_{CO_2} + 9\bar{h}_{H_2O} = (8)(177,822) + (9)(150,272) = 2,775,024 \text{ kJ}$$

By extrapolation, we get $T_P = 3597$ K. However, the solution of this problem using EES gives **5645 K**. The large difference between these two values is due to extrapolation.

15-105 Liquid propane, C_3H_8 (liq) is burned with 150 percent excess air. The balanced combustion equation is to be written and the mass flow rate of air, the average molar mass of the product gases, the average specific heat of the product gases at constant pressure are to be determined.

Assumptions 1 Combustion is complete. **2** The combustion products contain CO_2 , H_2O , O_2 , and N_2 only.

Properties The molar masses of C, H_2 , O_2 , N_2 , and air are 12, 2, 32, 28, and 29 kg/kmol, respectively (Table A-1).

Analysis The reaction equation for 150% excess air is

where a_{th} is the stoichiometric coefficient for air. We have automatically accounted for the 150% excess air by using the factor $2.5a_{th}$ instead of a_{th} for air. The coefficient a_{th} and other coefficients are to be determined from the mass balances

$$\text{Carbon balance:} \quad B = 3$$

$$\text{Hydrogen balance:} \quad 2D = 8 \longrightarrow D = 4$$

$$\text{Oxygen balance:} \quad 2 \times 2.5a_{th} = 2B + D + 2E$$

$$1.5a_{th} = E$$

$$\text{Nitrogen balance:} \quad 2.5a_{th} \times 3.76 = F$$

Solving the above equations, we find the coefficients ($E = 7.5$, $F = 47$, and $a_{th} = 5$) and write the balanced reaction equation as

The fuel flow rate is

$$\dot{N}_{fuel} = \frac{\dot{m}_{fuel}}{M_{fuel}} = \frac{0.4 \text{ kg/min}}{44 \text{ kg/kmol}} = 0.009071 \text{ kmol/min}$$

The air-fuel ratio is determined by taking the ratio of the mass of the air to the mass of the fuel,

$$AF = \frac{m_{air}}{m_{fuel}} = \frac{(12.5 \times 4.76 \text{ kmol})(29 \text{ kg/kmol})}{(1 \text{ kmol})(44 \text{ kg/kmol})} = 39.08 \text{ kg air/kg fuel}$$

Then, the mass flow rate of air becomes

$$\dot{m}_{air} = AF\dot{m}_{fuel} = (39.08)(0.4 \text{ kg/min}) = \mathbf{15.63 \text{ kg/min}}$$

The molar mass of the product gases is determined from

$$\begin{aligned} M_{prod} &= \frac{N_{CO_2}M_{CO_2} + N_{H_2O}M_{H_2O} + N_{O_2}M_{O_2} + N_{N_2}M_{N_2}}{N_{CO_2} + N_{H_2O} + N_{O_2} + N_{N_2}} \\ &= \frac{3(44) + 4(18) + 7.5(32) + 47(28)}{3 + 4 + 7.5 + 47} \\ &= \mathbf{28.63 \text{ kg/kmol}} \end{aligned}$$

The steady-flow energy balance is expressed as

$$\dot{N}_{fuel}H_R = \dot{Q}_{out} + \dot{N}_{fuel}H_P$$

where

$$\begin{aligned} H_R &= \bar{h}_{fuel@25^\circ C}^o - \bar{h}_{fg} + 12.5\bar{h}_{O_2@25^\circ C} + 47\bar{h}_{N_2@25^\circ C} \\ &= (-103,847 \text{ kJ/kmol} - 40,525 \text{ kJ/kmol}) + 12.5(0) + 47(0) \\ &= -144,372 \text{ kJ/kmol} \end{aligned}$$

$$H_P = 3\bar{h}_{CO_2@T_p} + 4\bar{h}_{H_2O@T_p} + 7.5\bar{h}_{O_2@T_p} + 47\bar{h}_{N_2@T_p}$$

Substituting into the energy balance equation,

$$\dot{N}_{\text{fuel}}H_R = \dot{Q}_{\text{out}} + \dot{N}_{\text{fuel}}H_P$$

$$(0.009071 \text{ kmol/min})(-144,372 \text{ kJ/kmol}) = (53 \times 60) \text{ kJ/min} + (0.009071 \text{ kmol/min})H_P$$

$$H_P = -150,215 \text{ kJ/kmol}$$

Substituting this value into the H_P relation above and by a trial-error approach or using EES, we obtain the temperature of the products of combustion

$$T_P = \mathbf{1282K}$$

The average constant pressure specific heat of the combustion gases can be determined from

$$C_{p,\text{prod}} = \frac{N_{\text{CO}_2}C_{\text{CO}_2@1282\text{K}} + N_{\text{H}_2\text{O}}C_{\text{H}_2\text{O}@1282\text{K}} + N_{\text{O}_2}C_{\text{O}_2@1282\text{K}} + N_{\text{N}_2}C_{\text{N}_2@1282\text{K}}}{N_{\text{CO}_2} + N_{\text{H}_2\text{O}} + N_{\text{O}_2} + N_{\text{N}_2}}$$

$$= \frac{3(56.94) + 4(44.62) + 7.5(35.9) + 47(34.02)}{3 + 4 + 7.5 + 47}$$

$$= \mathbf{36.06 \text{ kJ/kmol}\cdot\text{K}}$$

where the specific heat values of the gases are determined from EES.

15-106E The work potential of diesel fuel at a given state is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Air and combustion gases are ideal gases. 3 Kinetic and potential energies are negligible.

Analysis The work potential or availability of a fuel at a specified state is the reversible work that would be obtained if that fuel were burned completely with stoichiometric amount of air and the products are returned to the state of the surroundings. It is determined from

$$W_{\text{rev}} = \sum N_R (\bar{h}_f^\circ + \bar{h} + \bar{h}^\circ - T_0 \bar{s})_R - \sum N_P (\bar{h}_f^\circ + \bar{h} + \bar{h}^\circ - T_0 \bar{s})_P$$

or,
$$W_{\text{rev}} = \sum N_R (\bar{h}_f^\circ - T_0 \bar{s})_R - \sum N_P (\bar{h}_f^\circ - T_0 \bar{s})_P$$

since both the reactants and the products are at the state of the surroundings. Considering 1 kmol of $\text{C}_{12}\text{H}_{26}$, the theoretical combustion equation can be written as

where a_{th} is the stoichiometric coefficient and is determined from the O_2 balance,

$$a_{\text{th}} = 12 + 6.5 \longrightarrow a_{\text{th}} = 18.5$$

Substituting,
$$\text{C}_{12}\text{H}_{26} + 18.5(\text{O}_2 + 3.76\text{N}_2) \longrightarrow 12\text{CO}_2 + 13\text{H}_2\text{O} + 69.56\text{N}_2$$

For each lbmol of fuel burned, $12 + 13 + 69.56 = 94.56$ lbmol of products are formed, including 13 lbmol of H_2O . Assuming that the dew-point temperature of the products is above 77°F , some of the water will exist in the liquid form in the products. If N_w lbmol of H_2O condenses, there will be $13 - N_w$ lbmol of water vapor left in the products. The mole number of the products in the gas phase will also decrease to $94.56 - N_w$ as a result. Treating the product gases (including the remaining water vapor) as ideal gases, N_w is determined by equating the mole fraction of the water vapor to pressure fraction,

$$\frac{N_v}{N_{\text{prod gas}}} = \frac{P_v}{P_{\text{prod}}} \longrightarrow \frac{13 - N_w}{94.56 - N_w} = \frac{0.4648 \text{ psia}}{14.7 \text{ psia}} \longrightarrow N_w = 10.34 \text{ lbmol}$$

since $P_v = P_{\text{sat}} @ 77^\circ\text{F} = 0.4648$ psia. Then the combustion equation can be written as

The entropy values listed in the ideal gas tables are for 1 atm pressure. Both the air and the product gases are at a total pressure of 1 atm, but the entropies are to be calculated at the partial pressure of the components which is equal to $P_i = y_i P_{\text{total}}$, where y_i is the mole fraction of component i . Also,

$$S_i = N_i \bar{s}_i(T, P_i) = N_i (\bar{s}_i^\circ(T, P_0) - R_u \ln(y_i P_m))$$

The entropy calculations can be presented in tabular form as

	N_i	y_i	$\bar{s}_i^\circ(77^\circ\text{F}, 1\text{atm})$	$R_u \ln(y_i P_m)$	\bar{s}_i	$h_f^\circ, \text{Btu/lbmol}$
$\text{C}_{12}\text{H}_{26}$	1	---	148.86	---	148.86	-125,190
O_2	18.5	0.21	49.00	-3.10	52.10	0
N_2	69.56	0.79	45.77	-0.47	46.24	0
CO_2	12	0.1425	51.07	-3.870	54.94	-169,300
$\text{H}_2\text{O}(\text{g})$	2.66	0.0316	45.11	-6.861	51.97	-104,040
$\text{H}_2\text{O}(\ell)$	10.34	---	16.71	---	16.71	-122,970
N_2	69.56	0.8259	45.77	-0.380	46.15	0

Substituting,

$$\begin{aligned} W_{\text{rev}} &= (1)(-125,190 - 537 \times 148.86) + (18.5)(0 - 537 \times 52.10) + (69.56)(0 - 537 \times 46.24) \\ &\quad - (12)(-169,300 - 537 \times 54.94) - (2.66)(-104,040 - 537 \times 51.97) \\ &\quad - (10.34)(-122,970 - 537 \times 16.71) - (69.56)(0 - 537 \times 46.15) \\ &= \mathbf{3,375,000 \text{ Btu}} \text{ (per lbmol } \text{C}_{12}\text{H}_{26}\text{)} \end{aligned}$$

15-107 n-Octane is burned with 30 percent excess air. The combustion is incomplete. The maximum work that can be produced is to be determined.

Assumptions 1 Combustion is incomplete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.

Analysis The combustion equation with 30% excess air and 10% CO is

The coefficient for O_2 is determined from its mass balance as

$$1.3 \times 12.5 = 7.2 + 0.4 + 4.5 + x \longrightarrow x = 4.15$$

Substituting,

The reactants and products are at 25°C and 1 atm, which is the standard reference state and also the state of the surroundings. Therefore, the reversible work in this case is simply the difference between the Gibbs function of formation of the reactants and that of the products,

$$\begin{aligned} W_{\text{rev}} &= \sum N_R \bar{g}_{f,R}^\circ - \sum N_P \bar{g}_{f,P}^\circ \\ &= (1)(16,530) - (7.2)(-394,360) - (0.8)(-137,150) - (9)(-228,590) \\ &= 5,022,952 \text{ kJ (per kmol of fuel)} \end{aligned}$$

since the g_f° of stable elements at 25°C and 1 atm is zero. Per unit mass basis,

$$W_{\text{rev}} = \frac{5,022,952 \text{ kJ/kmol}}{114 \text{ kg/kmol}} = \mathbf{44,060 \text{ kJ/kg fuel}}$$

15-108 Methane is burned steadily with 50 percent excess air in a steam boiler. The amount of steam generated per unit of fuel mass burned, the change in the exergy of the combustion streams, the change in the exergy of the steam stream, and the lost work potential are to be determined.

Assumptions 1 Combustion is complete. **2** Steady operating conditions exist. **3** Air and the combustion gases are ideal gases. **4** Changes in kinetic and potential energies are negligible.

Properties The molar masses of CH₄ and air are 16 kg/kmol and 29 kg/kmol, respectively (Table A-1).

Analysis (a) The fuel is burned completely with the excess air, and thus the products will contain only CO₂, H₂O, N₂, and some free O₂. Considering 1 kmol CH₄, the combustion equation can be written as

Under steady-flow conditions the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $W = 0$ reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{K}}$ kJ/kmol	$\bar{h}_{500\text{K}}$ kJ/kmol
CH ₄	-74,850	---	---
O ₂	0	8682	14,770
N ₂	0	8669	14,581
H ₂ O (g)	-241,820	9904	16,828
CO ₂	-393,520	9364	17,678

Thus,

$$\begin{aligned} -Q_{\text{out}} &= (1)(-393,520 + 17,678 - 9364) + (2)(-241,820 + 16,828 - 9904) \\ &\quad + (1)(0 + 14,770 - 8682) + (11.28)(0 + 14,581 - 8669) - (1)(-74,850) \\ &= -707,373 \text{ kJ/kmol of fuel} \end{aligned}$$

The heat loss per unit mass of the fuel is

$$Q_{\text{out}} = \frac{707,373 \text{ kJ/kmol of fuel}}{16 \text{ kg/kmol of fuel}} = 44,211 \text{ kJ/kg fuel}$$

The amount of steam generated per unit mass of fuel burned is determined from an energy balance to be (Enthalpies of steam are from tables A-4 and A-6)

$$\frac{m_s}{m_f} = \frac{Q_{\text{out}}}{\Delta h_s} = \frac{44,211 \text{ kJ/kg fuel}}{(3214.5 - 852.26) \text{ kJ/kg steam}} = \mathbf{18.72 \text{ kg steam/kg fuel}}$$

(b) The entropy generation during this process is determined from

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{out}}}{T_{\text{surr}}} = \sum N_P \bar{s}_P - \sum N_R \bar{s}_R + \frac{Q_{\text{out}}}{T_{\text{surr}}}$$

The entropy values listed in the ideal gas tables are for 1 atm pressure. Both the air and the product gases are at a total pressure of 1 atm, but the entropies are to be calculated at the partial pressure of the components which is equal to $P_i = y_i P_{\text{total}}$, where y_i is the mole fraction of component i . Then,

$$S_i = N_i \bar{s}_i(T, P_i) = N_i \left(\bar{s}_i^\circ(T, P_0) - R_u \ln(y_i P_m) \right)$$

The entropy calculations can be presented in tabular form as

	N_i	y_i	$\bar{s}_i^\circ(T, 1\text{atm})$	$R_u \ln(y_i P_m)$	$N_i \bar{s}_i$
CH ₄	1	---	186.16	0	186.16
O ₂	3	0.21	205.04	-12.98	654.06
N ₂	11.28	0.79	191.61	-1.960	2183.47
					$S_R = 3023.69 \text{ kJ/K}$
CO ₂	1	0.0654	234.814	-22.67	257.48
H ₂ O (g)	2	0.1309	206.413	-16.91	446.65
O ₂	1	0.0654	220.589	-22.67	243.26
N ₂	11.28	0.7382	206.630	-2.524	2359.26
					$S_P = 3306.65 \text{ kJ/K}$

Thus,

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{out}}}{T_{\text{surr}}} = 3306.65 - 3023.69 + \frac{707,373}{298} = 2657 \text{ kJ/K (per kmol fuel)}$$

The exergy change of the combustion streams is equal to the exergy destruction since there is no actual work output. That is,

$$\Delta X_{\text{gases}} = -X_{\text{dest}} = -T_0 S_{\text{gen}} = -(298 \text{ K})(2657 \text{ kJ/K}) = -791,786 \text{ kJ/kmol fuel}$$

Per unit mass basis,

$$\Delta X_{\text{gases}} = \frac{-791,786 \text{ kJ/kmol fuel}}{16 \text{ kg/kmol}} = \mathbf{-49,490 \text{ kJ/kg fuel}}$$

Note that the exergy change is negative since the exergy of combustion gases decreases.

(c) The exergy change of the steam stream is

$$\Delta X_{\text{steam}} = \Delta h - T_0 \Delta s = (3214.5 - 852.26) - (298)(6.7714 - 2.3305) = \mathbf{1039 \text{ kJ/kg steam}}$$

(d) The lost work potential is the negative of the net exergy change of both streams:

$$\begin{aligned} X_{\text{dest}} &= - \left(\frac{m_s}{m_f} \Delta X_{\text{steam}} + \Delta X_{\text{gases}} \right) \\ &= - [(18.72 \text{ kg steam/kg fuel})(1039 \text{ kJ/kg steam}) + (-49,490 \text{ kJ/kg fuel})] \\ &= \mathbf{30,040 \text{ kJ/kg fuel}} \end{aligned}$$

15-109 A coal from Utah is burned steadily with 50 percent excess air in a steam boiler. The amount of steam generated per unit of fuel mass burned, the change in the exergy of the combustion streams, the change in the exergy of the steam stream, and the lost work potential are to be determined.

Assumptions 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible. 5 The effect of sulfur on the energy and entropy balances is negligible.

Properties The molar masses of C, H₂, N₂, O₂, S, and air are 12, 2, 28, 32, 32, and 29 kg/kmol, respectively (Table A-1).

Analysis (a) We consider 100 kg of coal for simplicity. Noting that the mass percentages in this case correspond to the masses of the constituents, the mole numbers of the constituent of the coal are determined to be

$$N_C = \frac{m_C}{M_C} = \frac{61.40 \text{ kg}}{12 \text{ kg/kmol}} = 5.117 \text{ kmol}$$

$$N_{H_2} = \frac{m_{H_2}}{M_{H_2}} = \frac{5.79 \text{ kg}}{2 \text{ kg/kmol}} = 2.895 \text{ kmol}$$

$$N_{O_2} = \frac{m_{O_2}}{M_{O_2}} = \frac{25.31 \text{ kg}}{32 \text{ kg/kmol}} = 0.7909 \text{ kmol}$$

$$N_{N_2} = \frac{m_{N_2}}{M_{N_2}} = \frac{1.09 \text{ kg}}{28 \text{ kg/kmol}} = 0.03893 \text{ kmol}$$

$$N_S = \frac{m_S}{M_S} = \frac{1.41 \text{ kg}}{32 \text{ kg/kmol}} = 0.04406 \text{ kmol}$$

61.40% C
5.79% H ₂
25.31% O ₂
1.09% N ₂
1.41% S
5.00% ash (by mass)

The mole number of the mixture and the mole fractions are

$$N_m = 5.117 + 2.895 + 0.7909 + 0.03893 + 0.04406 = 8.886 \text{ kmol}$$

$$y_C = \frac{N_C}{N_m} = \frac{5.117 \text{ kmol}}{8.886 \text{ kmol}} = 0.5758$$

$$y_{H_2} = \frac{N_{H_2}}{N_m} = \frac{2.895 \text{ kmol}}{8.886 \text{ kmol}} = 0.3258$$

$$y_{O_2} = \frac{N_{O_2}}{N_m} = \frac{0.7909 \text{ kmol}}{8.886 \text{ kmol}} = 0.0890$$

$$y_{N_2} = \frac{N_{N_2}}{N_m} = \frac{0.03893 \text{ kmol}}{8.886 \text{ kmol}} = 0.00438$$

$$y_S = \frac{N_S}{N_m} = \frac{0.04406 \text{ kmol}}{8.886 \text{ kmol}} = 0.00496$$

Ash consists of the non-combustible matter in coal. Therefore, the mass of ash content that enters the combustion chamber is equal to the mass content that leaves. Disregarding this non-reacting component for simplicity, the combustion equation may be written as

According to the oxygen balance,

$$O_2 \text{ balance: } 0.0890 + 1.5a_{th} = 0.5758 + 0.5 \times 0.3258 + 0.00496 + 0.5a_{th} \longrightarrow a_{th} = 0.6547$$

Substituting,

The apparent molecular weight of the coal is

$$\begin{aligned}
 M_m &= \frac{m_m}{N_m} \\
 &= \frac{(0.5758 \times 12 + 0.3258 \times 2 + 0.0890 \times 32 + 0.00438 \times 28 + 0.00496 \times 32) \text{ kg}}{(0.5758 + 0.3258 + 0.0890 + 0.00438 + 0.00496) \text{ kmol}} \\
 &= \frac{10.69 \text{ kg}}{1.0 \text{ kmol}} \\
 &= 10.69 \text{ kg/kmol coal}
 \end{aligned}$$

Under steady-flow conditions the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $W = 0$ reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{K}}$ kJ/kmol	$\bar{h}_{500\text{K}}$ kJ/kmol
O ₂	0	8682	14,770
N ₂	0	8669	14,581
H ₂ O (g)	-241,820	9904	16,828
CO ₂	-393,520	9364	17,678

Thus,

$$\begin{aligned}
 -Q_{\text{out}} &= (0.5758)(-393,520 + 17,678 - 9364) + (0.3258)(-241,820 + 16,828 - 9904) \\
 &\quad + (0.3274)(0 + 14,770 - 8682) + (3.693)(0 + 14,581 - 8669) - 0 \\
 &= -274,505 \text{ kJ/kmol of fuel}
 \end{aligned}$$

The heat loss per unit mass of the fuel is

$$Q_{\text{out}} = \frac{274,505 \text{ kJ/kmol of fuel}}{10.69 \text{ kg/kmol of fuel}} = 25,679 \text{ kJ/kg fuel}$$

The amount of steam generated per unit mass of fuel burned is determined from an energy balance to be (Enthalpies of steam are from tables A-4 and A-6)

$$\frac{m_s}{m_f} = \frac{Q_{\text{out}}}{\Delta h_s} = \frac{25,679 \text{ kJ/kg fuel}}{(3214.5 - 852.26) \text{ kJ/kg steam}} = \mathbf{10.87 \text{ kg steam/kg fuel}}$$

(b) The entropy generation during this process is determined from

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{out}}}{T_{\text{surr}}} = \sum N_P \bar{s}_P - \sum N_R \bar{s}_R + \frac{Q_{\text{out}}}{T_{\text{surr}}}$$

The entropy values listed in the ideal gas tables are for 1 atm pressure. Both the air and the product gases are at a total pressure of 1 atm, but the entropies are to be calculated at the partial pressure of the components which is equal to $P_i = y_i P_{\text{total}}$, where y_i is the mole fraction of component i . Then,

$$S_i = N_i \bar{s}_i(T, P_i) = N_i (\bar{s}_i^\circ(T, P_0) - R_u \ln(y_i P_m))$$

The entropy calculations can be presented in tabular form as

	N_i	y_i	$\bar{s}_i^\circ(T, 1\text{atm})$	$R_u \ln(y_i P_m)$	$N_i \bar{s}_i$
C	0.5758	0.5758	5.74	-4.589	5.95
H ₂	0.3258	0.3258	130.68	-9.324	45.61
O ₂	0.0890	0.0890	205.04	-20.11	20.04
N ₂	0.00438	0.00438	191.61	-45.15	1.04
O ₂	0.9821	0.21	205.04	-12.98	214.12
N ₂	3.693	0.79	191.61	-1.960	714.85
					$S_R = 1001.61 \text{ kJ/K}$
CO ₂	0.5758	0.1170	234.814	-17.84	145.48
H ₂ O (g)	0.3258	0.0662	206.413	-22.57	74.60
O ₂	0.3274	0.0665	220.589	-22.54	79.60
N ₂	3.693	0.7503	206.630	-2.388	771.90
					$S_P = 1071.58 \text{ kJ/K}$

Thus,

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{out}}}{T_{\text{surr}}} = 1071.58 - 1001.61 + \frac{274,505}{298} = 991.1 \text{ kJ/K (per kmol fuel)}$$

The exergy change of the combustion streams is equal to the exergy destruction since there is no actual work output. That is,

$$\Delta X_{\text{gases}} = -X_{\text{dest}} = -T_0 S_{\text{gen}} = -(298 \text{ K})(991.1 \text{ kJ/K}) = -295,348 \text{ kJ/kmol fuel}$$

Per unit mass basis,

$$\Delta X_{\text{gases}} = \frac{-295,348 \text{ kJ/K}}{10.69 \text{ kg/kmol}} = \mathbf{-27,630 \text{ kJ/kg fuel}}$$

Note that the exergy change is negative since the exergy of combustion gases decreases.

(c) The exergy change of the steam stream is

$$\Delta X_{\text{steam}} = \Delta h - T_0 \Delta s = (3214.5 - 852.26) - (298)(6.7714 - 2.3305) = \mathbf{1039 \text{ kJ/kg steam}}$$

(d) The lost work potential is the negative of the net exergy change of both streams:

$$\begin{aligned} X_{\text{dest}} &= - \left(\frac{m_s}{m_f} \Delta X_{\text{steam}} + \Delta X_{\text{gases}} \right) \\ &= - \left[(10.87 \text{ kg steam/kg fuel})(1039 \text{ kJ/kg steam}) + (-27,630 \text{ kJ/kg fuel}) \right] \\ &= \mathbf{16,340 \text{ kJ/kg fuel}} \end{aligned}$$

15-110 Liquid octane is burned with 200 percent excess air during a steady-flow combustion process. The heat transfer rate from the combustion chamber, the power output of the turbine, and the reversible work and exergy destruction are to be determined.

Assumptions 1 Combustion is complete. 2 Steady operating conditions exist. 3 Air and the combustion gases are ideal gases. 4 Changes in kinetic and potential energies are negligible.

Properties The molar mass of C_8H_{18} is 114 kg/kmol (Table A-1).

Analysis (a) The fuel is burned completely with the excess air, and thus the products will contain only CO_2 , H_2O , N_2 , and some free O_2 . Considering 1 kmol of C_8H_{18} , the combustion equation can be written as

where a_{th} is the stoichiometric coefficient and is determined from the O_2 balance,

$$3a_{th} = 8 + 4.5 + 2a_{th} \longrightarrow a_{th} = 12.5$$

Substituting,

The heat transfer for this combustion process is determined from the energy balance $E_{in} - E_{out} = \Delta E_{system}$ applied on the combustion chamber with $W = 0$,

$$-Q_{out} = \sum N_P(\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R(\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{500\text{ K}}$ kJ/kmol	$\bar{h}_{298\text{ K}}$ kJ/kmol	$\bar{h}_{1300\text{ K}}$ kJ/kmol	$\bar{h}_{950\text{ K}}$ kJ/kmol
$C_8H_{18}(\ell)$	-249,950	---	---	---	---
O_2	0	14,770	8682	42,033	26,652
N_2	0	14,581	8669	40,170	28,501
$H_2O(g)$	-241,820	---	9904	48,807	33,841
CO_2	-393,520	---	9364	59,552	40,070

Substituting,

$$\begin{aligned} -Q_{out} &= (8)(-393,520 + 59,522 - 9364) + (9)(-241,820 + 48,807 - 9904) \\ &\quad + (25)(0 + 42,033 - 8682) + (141)(0 + 40,170 - 8669) \\ &\quad - (1)(-249,950 + h_{298} - h_{298}) - (37.5)(0 + 14,770 - 8682) - (141)(0 + 14,581 - 8669) \\ &= -109,675 \text{ kJ/kmol } C_8H_{18} \end{aligned}$$

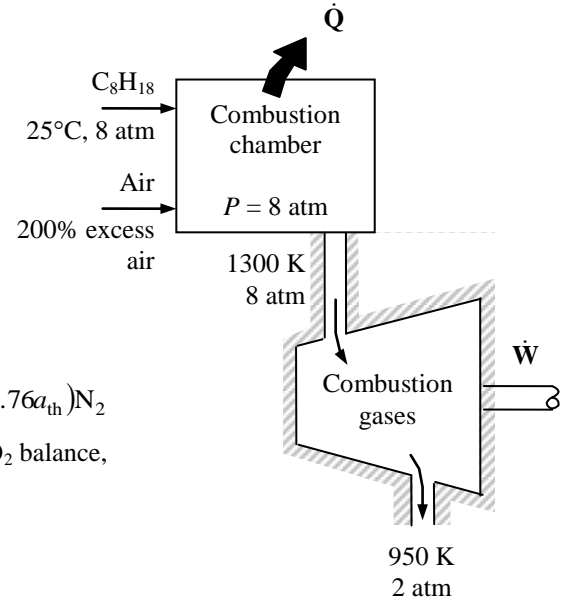

The C_8H_{18} is burned at a rate of 0.8 kg/min or

$$\dot{N} = \frac{\dot{m}}{M} = \frac{0.8 \text{ kg/min}}{((8)(12) + (18)(1)) \text{ kg/kmol}} = 7.018 \times 10^{-3} \text{ kmol/min}$$

Thus,

$$\dot{Q}_{out} = \dot{N}Q_{out} = (7.018 \times 10^{-3} \text{ kmol/min})(109,675 \text{ kJ/kmol}) = \mathbf{770 \text{ kJ/min}}$$

(b) Noting that no chemical reactions occur in the turbine, the turbine is adiabatic, and the product gases can be treated as ideal gases, the power output of the turbine can be determined from the steady-flow energy balance equation for nonreacting gas mixtures,

$$-W_{\text{out}} = \sum N_P (\bar{h}_e - \bar{h}_i) \longrightarrow W_{\text{out}} = \sum N_P (\bar{h}_{1300\text{K}} - \bar{h}_{950\text{K}})$$

Substituting,

$$W_{\text{out}} = (8)(59,522 - 40,070) + (9)(48,807 - 33,841) + (25)(42,033 - 29,652) + (141)(40,170 - 28,501) \\ = 2,245,164 \text{ kJ/kmol C}_8\text{H}_{18}$$

Thus the power output of the turbine is

$$\dot{W}_{\text{out}} = \dot{N}W_{\text{out}} = (7.018 \times 10^{-3} \text{ kmol/min})(2,245,164 \text{ kJ/kmol}) = 15,756 \text{ kJ/min} = \mathbf{262.6 \text{ kW}}$$

(c) The entropy generation during this process is determined from

$$S_{\text{gen}} = S_P - S_R + \frac{Q_{\text{out}}}{T_{\text{sur}}} = \sum N_P \bar{s}_P - \sum N_R \bar{s}_R + \frac{Q_{\text{out}}}{T_{\text{sur}}}$$

where the entropy of the products are to be evaluated at the turbine exit state. The C_8H_{18} is at 25°C and 8 atm, and thus its absolute entropy is $\bar{s}_{\text{C}_8\text{H}_{18}} = 360.79 \text{ kJ/kmol}\cdot\text{K}$ (Table A-26). The entropy values listed in the ideal gas tables are for 1 atm pressure. The entropies are to be calculated at the partial pressure of the components which is equal to $P_i = y_i P_{\text{total}}$, where y_i is the mole fraction of component i . Also,

$$S_i = N_i \bar{s}_i(T, P_i) = N_i (\bar{s}_i^\circ(T, P_0) - R_u \ln(y_i P_m))$$

The entropy calculations can be presented in tabular form as

	N_i	y_i	$\bar{s}_i^\circ(\mathbf{T}, \mathbf{1 atm})$	$\mathbf{R}_u \ln(y_i P_m)$	$N_i \bar{s}_i$
C_8H_{18}	1	1.00	360.79	17.288	343.50
O_2	37.5	0.21	220.589	4.313	8,110.34
N_2	141	0.79	206.630	15.329	26,973.44
$S_R = 35,427.28 \text{ kJ/K}$					
CO_2	8	0.0437	266.444	-20.260	2,293.63
H_2O	9	0.0490	230.499	-19.281	2,248.02
O_2	25	0.1366	241.689	-10.787	6,311.90
N_2	141	0.7705	226.389	3.595	31,413.93
$S_P = 42,267.48 \text{ kJ/K}$					

Thus,

$$S_{\text{gen}} = 42,267.48 - 35,427.28 + \frac{109,675 \text{ kJ}}{298 \text{ K}} = 7208.2 \text{ kJ/K (per kmol)}$$

Then the rate of entropy generation becomes

$$\dot{S}_{\text{gen}} = \dot{N}S_{\text{gen}} = (7.018 \times 10^{-3} \text{ kmol/min})(7208.2 \text{ kJ/kmol}\cdot\text{K}) = 50.59 \text{ kJ/min}\cdot\text{K}$$

and

$$\dot{X}_{\text{destruction}} = T_0 \dot{S}_{\text{gen}} = (298 \text{ K})(50.59 \text{ kJ/min}\cdot\text{K}) = 15,076 \text{ kJ/min} = \mathbf{251.3 \text{ kW}}$$

$$\dot{W}_{\text{rev}} = \dot{W} + \dot{X}_{\text{destruction}} = 262.6 + 251.3 = \mathbf{513.9 \text{ kW}}$$

15-111 An expression for the HHV of a gaseous alkane C_nH_{2n+2} in terms of n is to be developed.

Assumptions **1** Combustion is complete. **2** The combustion products contain CO_2 , H_2O , and N_2 . **3** Combustion gases are ideal gases.

Analysis The complete reaction balance for 1 kmol of fuel is

Both the reactants and the products are taken to be at the standard reference state of $25^\circ C$ and 1 atm for the calculation of heating values. The heat transfer for this process is equal to enthalpy of combustion. Note that N_2 and O_2 are stable elements, and thus their enthalpy of formation is zero. Then,

$$q = h_C = H_P - H_R = \sum N_P \bar{h}_{f,P} - \sum N_R \bar{h}_{f,R} = (N\bar{h}_f)_{CO_2} + (N\bar{h}_f)_{H_2O} - (N\bar{h}_f)_{fuel}$$

For the HHV, the water in the products is taken to be liquid. Then,

$$h_C = n(-393,520) + (n+1)(-285,830) - (\bar{h}_f)_{fuel}$$

The HHV of the fuel is

$$HHV = \frac{-h_C}{M_{fuel}} = \frac{n(-393,520) + (n+1)(-285,830) - (\bar{h}_f)_{fuel}}{M_{fuel}}$$

For the LHV, the water in the products is taken to be vapor. Then,

$$LHV = \frac{n(-393,520) + (n+1)(-241,820) - (\bar{h}_f)_{fuel}}{M_{fuel}}$$

15-112 It is to be shown that the work output of the Carnot engine will be maximum when $T_p = \sqrt{T_0 T_{af}}$. It is also to be shown that the maximum work output of the Carnot engine in this case becomes $w = CT_{af} \left(1 - \frac{\sqrt{T_0}}{\sqrt{T_{af}}}\right)^2$.

Analysis The combustion gases will leave the combustion chamber and enter the heat exchanger at the adiabatic flame temperature T_{af} since the chamber is adiabatic and the fuel is burned completely. The combustion gases experience no change in their chemical composition as they flow through the heat exchanger. Therefore, we can treat the combustion gases as a gas stream with a constant specific heat c_p . Noting that the heat exchanger involves no work interactions, the energy balance equation for this single-stream steady-flow device can be written as

$$\dot{Q} = \dot{m}(h_e - h_i) = \dot{m}C(T_p - T_{af})$$

where \dot{Q} is the negative of the heat supplied to the heat engine. That is,

$$\dot{Q}_H = -\dot{Q} = \dot{m}C(T_{af} - T_p)$$

Then the work output of the Carnot heat engine can be expressed as

$$\dot{W} = \dot{Q}_H \left(1 - \frac{T_0}{T_p}\right) = \dot{m}C(T_{af} - T_p) \left(1 - \frac{T_0}{T_p}\right) \quad (1)$$

Taking the partial derivative of \dot{W} with respect to T_p while holding T_{af} and T_0 constant gives

$$\frac{\partial \dot{W}}{\partial T_p} = 0 \longrightarrow -\dot{m}C \left(1 - \frac{T_0}{T_p}\right) + \dot{m}C(T_{af} - T_p) \frac{T_0}{T_p^2} = 0$$

Solving for T_p we obtain

$$T_p = \sqrt{T_0 T_{af}}$$

which is the temperature at which the work output of the Carnot engine will be a maximum. The maximum work output is determined by substituting the relation above into Eq. (1),

$$\dot{W} = \dot{m}C(T_{af} - T_p) \left(1 - \frac{T_0}{T_p}\right) = \dot{m}C(T_{af} - \sqrt{T_0 T_{af}}) \left(1 - \frac{T_0}{\sqrt{T_0 T_{af}}}\right)$$

It simplifies to

$$\dot{W} = \dot{m}CT_{af} \left(1 - \frac{\sqrt{T_0}}{\sqrt{T_{af}}}\right)^2$$

or

$$w = CT_{af} \left(1 - \frac{\sqrt{T_0}}{\sqrt{T_{af}}}\right)^2$$

which is the desired relation.

15-113 The combustion of a hydrocarbon fuel C_nH_m with excess air and incomplete combustion is considered. The coefficients of the reactants and products are to be written in terms of other parameters.

Analysis The balanced reaction equation for stoichiometric air is

The stoichiometric coefficient A_{th} is determined from an O_2 balance:

$$A_{th} = n + m/4$$

The reaction with excess air and incomplete combustion is

The given reaction is

Thus,

$$D = a n$$

$$E = b n$$

$$F = m/2$$

$$J = 3.76(1+B)A_{th}$$

The coefficient G for O_2 is determined from a mass balance,

O_2 balance:

$$\begin{aligned} (1+B)A_{th} &= a n + \frac{b n}{2} + \frac{m}{4} + G \\ (1+B)\left(n + \frac{m}{4}\right) &= a n + \frac{b n}{2} + \frac{m}{4} + G \\ \left(n + \frac{m}{4}\right) + B A_{th} &= a n + \frac{b n}{2} + \frac{m}{4} + G \\ G &= n + B A_{th} - a n - \frac{b n}{2} \\ &= n(1-a) + B A_{th} - \frac{b n}{2} \\ &= n b - \frac{b n}{2} + B A_{th} \\ &= \frac{b n}{2} + B A_{th} \end{aligned}$$

15-114 The combustion of a mixture of an alcohol fuel ($C_nH_mO_x$) and a hydrocarbon fuel (C_wH_z) with excess air and incomplete combustion is considered. The coefficients of the reactants and products are to be written in terms of other parameters.

Analysis The balanced reaction equation for stoichiometric air is

The stoichiometric coefficient A_{th} is determined from an O_2 balance:

$$y_1 x / 2 + A_{th} = (y_1 n + y_2 w) + (y_1 m + y_2 z) / 4 \longrightarrow A_{th} = (y_1 n + y_2 w) + (y_1 m + y_2 z) / 4 - y_1 x / 2$$

The reaction with excess air and incomplete combustion is

The given reaction is

Thus,

$$D = a(y_1 n + y_2 w)$$

$$E = b(y_1 n + y_2 w)$$

$$F = 0.5(y_1 m + y_2 z)$$

$$J = 3.76(1 + B)A_{th}$$

The coefficient G for O_2 is determined from a mass balance,

O_2 balance:

$$0.5y_1 x + (1 + B)A_{th} = a(y_1 n + y_2 w) + 0.5b(y_1 n + y_2 w) + 0.25(y_1 m + y_2 z) + G$$

$$0.5y_1 x + (y_1 n + y_2 w) + 0.25(y_1 m + y_2 z) - 0.5y_1 x + BA_{th} = a(y_1 n + y_2 w) + 0.5b(y_1 n + y_2 w) + 0.25(y_1 m + y_2 z) + G$$

$$G = (y_1 n + y_2 w) - a(y_1 n + y_2 w) - 0.5b(y_1 n + y_2 w) + BA_{th}$$

$$= (y_1 n + y_2 w)(1 - a) - 0.5b(y_1 n + y_2 w) + BA_{th}$$

$$= b(y_1 n + y_2 w) - 0.5b(y_1 n + y_2 w) + BA_{th}$$

$$= 0.5b(y_1 n + y_2 w) + BA_{th}$$

15-115 The adiabatic flame temperature of the fuels $\text{CH}_4(\text{g})$, $\text{C}_2\text{H}_2(\text{g})$, $\text{CH}_3\text{OH}(\text{g})$, $\text{C}_3\text{H}_8(\text{g})$, and $\text{C}_8\text{H}_{18}(\text{l})$ is to be determined.

Analysis The problem is solved using EES, and the solution is given below.

15-117 The fuel among $\text{CH}_4(\text{g})$, $\text{C}_2\text{H}_2(\text{g})$, $\text{C}_2\text{H}_6(\text{g})$, $\text{C}_3\text{H}_8(\text{g})$, and $\text{C}_8\text{H}_{18}(\text{l})$ that gives the highest temperature when burned completely in an adiabatic constant-volume chamber with the theoretical amount of air is to be determined.

Analysis The problem is solved using EES, and the solution is given below.

Adiabatic Combustion of fuel $\text{C}_x\text{H}_y\text{O}_z$ with Stoichiometric Air at $T_{\text{fuel}} = T_{\text{air}} = T_{\text{reac}}$ in a constant volume, closed system:

Reaction: $\text{C}_x\text{H}_y\text{O}_z + (x+y/4-z/2) (\text{Theo_air}/100) (\text{O}_2 + 3.76 \text{ N}_2)$
 $\rightarrow x\text{CO}_2 + (y/2) \text{H}_2\text{O} + 3.76 (x+y/4-z/2) (\text{Theo_air}/100) \text{N}_2 + (x+y/4-z/2) (\text{Theo_air}/100 - 1) \text{O}_2$

"For theoretical oxygen, the complete combustion equation for CH_3OH is"

" $\text{CH}_3\text{OH} + A_{\text{th}} \text{O}_2 = 1 \text{CO}_2 + 2 \text{H}_2\text{O}$ "

" $1 + 2 * A_{\text{th}} = 1 * 2 + 2 * 1$ " "theoretical O balance"

"Adiabatic, Incomplete Combustion of fuel $\text{C}_x\text{H}_y\text{O}_z$ with Stoichiometric Air at $T_{\text{fuel}} = T_{\text{air}} = T_{\text{reac}}$ in a constant volume, closed system:

Reaction: $\text{C}_x\text{H}_y\text{O}_z + (x+y/4-z/2) (\text{Theo_air}/100) (\text{O}_2 + 3.76 \text{ N}_2)$
 $\rightarrow (x-w)\text{CO}_2 + w\text{CO} + (y/2) \text{H}_2\text{O} + 3.76 (x+y/4-z/2) (\text{Theo_air}/100) \text{N}_2 + ((x+y/4-z/2) (\text{Theo_air}/100 - 1) + w/2) \text{O}_2$

" T_{prod} is the adiabatic combustion temperature, assuming no dissociation.

Theo_air is the % theoretical air. "

"The initial guess value of $T_{\text{prod}} = 450\text{K}$."

15-118 A general program is to be written to determine the heat transfer during the complete combustion of a hydrocarbon fuel C_nH_m at 25°C in a steady-flow combustion chamber when the percent of excess air and the temperatures of air and the products are specified.

Analysis The problem is solved using EES, and the solution is given below.

Steady-flow combustion of fuel C_nH_m entering at T_{fuel} with Stoichiometric Air at T_{air} :

Reaction: $C_xH_yO_z + (x+y/4-z/2) (\text{Theo_air}/100) (\text{O}_2 + 3.76 \text{N}_2)$

--> $x\text{CO}_2 + (y/2) \text{H}_2\text{O} + 3.76 (x+y/4-z/2) (\text{Theo_air}/100) \text{N}_2 + (x+y/4-z/2) (\text{Theo_air}/100 - 1) \text{O}_2$

"For theoretical oxygen, the complete combustion equation for CH_3OH is"

" $\text{CH}_3\text{OH} + A_{\text{th}} \text{O}_2 = 1 \text{CO}_2 + 2 \text{H}_2\text{O}$ "

" $1 + 2A_{\text{th}} = 1 + 2 \times 1$ " "theoretical O balance"

"Steady-flow, Incomplete Combustion of fuel C_nH_m entering at T_{fuel} with Stoichiometric Air at T_{air} :

Reaction: $C_xH_yO_z + (x+y/4-z/2) (\text{Theo_air}/100) (\text{O}_2 + 3.76 \text{N}_2)$

--> $(x-w)\text{CO}_2 + w\text{CO} + (y/2) \text{H}_2\text{O} + 3.76 (x+y/4-z/2) (\text{Theo_air}/100) \text{N}_2 + ((x+y/4-z/2) (\text{Theo_air}/100 - 1) + w/2) \text{O}_2$

" T_{prod} is the product gas temperature, assuming no dissociation.

Fundamentals of Engineering (FE) Exam Problems

15-121 A fuel is burned steadily in a combustion chamber. The combustion temperature will be the highest except when

- (a) the fuel is preheated.
- (b) the fuel is burned with a deficiency of air.
- (c) the air is dry.
- (d) the combustion chamber is well insulated.
- (e) the combustion is complete.

Answer (b) the fuel is burned with a deficiency of air.

15-122 A fuel is burned with 70 percent theoretical air. This is equivalent to

- (a) 30% excess air
- (b) 70% excess air
- (c) 30% deficiency of air
- (d) 70% deficiency of air
- (e) stoichiometric amount of air

Answer (c) 30% deficiency of air

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
air_th=0.7
"air_th=air_access+1"
air_th=1-air_deficiency
```

15-123 Propane C_3H_8 is burned with 150 percent theoretical air. The air-fuel mass ratio for this combustion process is

- (a) 5.3
- (b) 10.5
- (c) 15.7
- (d) 23.4
- (e) 39.3

Answer (d) 23.4

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
n_C=3
n_H=8
m_fuel=n_H*1+n_C*12

```

"Some Wrong Solutions with Common Mistakes:"

```
W1_Xdest=S_gen "Taking Sgen as exergy destruction"
W2_Xdest=To*S_gen1; S_react-S_prod-S_gen1=0 "Ignoring Q_out/To"
```

15-131 ... 15-136 Design and Essay Problems

15-134 A certain industrial process generates a liquid solution of ethanol and water as the waste product. The solution is to be burned using methane. A combustion process is to be developed to accomplish this incineration process with minimum amount of methane.

Analysis The mass flow rate of the liquid ethanol-water solution is given to be 10 kg/s. Considering that the mass fraction of ethanol in the solution is 0.2,

$$\begin{aligned}\dot{m}_{\text{ethanol}} &= (0.2)(10 \text{ kg/s}) = 2 \text{ kg/s} \\ \dot{m}_{\text{water}} &= (0.8)(10 \text{ kg/s}) = 8 \text{ kg/s}\end{aligned}$$

Noting that the molar masses $M_{\text{ethanol}} = 46$ and $M_{\text{water}} = 18$ kg/kmol and that mole numbers $N = m/M$, the mole flow rates become

$$\begin{aligned}\dot{N}_{\text{ethanol}} &= \frac{\dot{m}_{\text{ethanol}}}{M_{\text{ethanol}}} = \frac{2 \text{ kg/s}}{46 \text{ kg/kmol}} = 0.04348 \text{ kmol/s} \\ \dot{N}_{\text{water}} &= \frac{\dot{m}_{\text{water}}}{M_{\text{water}}} = \frac{8 \text{ kg/s}}{18 \text{ kg/kmol}} = 0.44444 \text{ kmol/s}\end{aligned}$$

Note that

$$\frac{\dot{N}_{\text{water}}}{\dot{N}_{\text{ethanol}}} = \frac{0.44444}{0.04348} = 10.222 \text{ kmol H}_2\text{O/kmol C}_2\text{H}_5\text{OH}$$

That is, 10.222 moles of liquid water is present in the solution for each mole of ethanol.

Assuming complete combustion, the combustion equation of $\text{C}_2\text{H}_5\text{OH}(\ell)$ with stoichiometric amount of air is

where a_{th} is the stoichiometric coefficient and is determined from the O_2 balance,

$$1 + 2a_{\text{th}} = 4 + 3 \longrightarrow a_{\text{th}} = 3$$

Thus,

Noting that 10.222 kmol of liquid water accompanies each kmol of ethanol, the actual combustion equation can be written as

The heat transfer for this combustion process is determined from the steady-flow energy balance equation with $W = 0$,

$$Q = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. We assume all the reactants to enter the combustion chamber at the standard reference temperature of 25°C. Furthermore, we assume the products to leave the combustion chamber at 1400 K which is a little over the required temperature of 1100°C. From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{ K}}$ kJ/kmol	$\bar{h}_{1400\text{ K}}$ kJ/kmol
C ₂ H ₅ OH (ℓ)	-277,690	---	---
CH ₄	-74,850	---	---
O ₂	0	8682	45,648
N ₂	0	8669	43,605
H ₂ O (g)	-241,820	9904	53,351
H ₂ O (ℓ)	-285,830	---	---
CO ₂	-393,520	9364	65,271

Thus,

$$\begin{aligned}
 Q &= (2)(-393,520 + 65,271 - 9364) + (3)(-241,820 + 53,351 - 9904) \\
 &\quad + (11.28)(0 + 43,605 - 8669) - (1)(-277,690) - 0 - 0 \\
 &\quad + (10.222)(-241,820 + 53,351 - 9904) - (10.222)(-285,830) \\
 &= 295,409 \text{ kJ/kmol of C}_2\text{H}_5\text{OH}
 \end{aligned}$$

The positive sign indicates that 295,409 kJ of heat must be supplied to the combustion chamber from another source (such as burning methane) to ensure that the combustion products will leave at the desired temperature of 1400 K. Then the rate of heat transfer required for a mole flow rate of 0.04348 kmol C₂H₅OH/s becomes

$$\dot{Q} = \dot{N}Q = (0.04348 \text{ kmol/s})(295,409 \text{ kJ/kmol}) = 12,844 \text{ kJ/s}$$

Assuming complete combustion, the combustion equation of CH₄(g) with stoichiometric amount of air is

where a_{th} is the stoichiometric coefficient and is determined from the O₂ balance,

Thus,

$$a_{\text{th}} = 1 + 1 \longrightarrow a_{\text{th}} = 2$$

The heat transfer for this combustion process is determined from the steady-flow energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ equation as shown above under the same assumptions and using the same mini table:

$$\begin{aligned}
 Q &= (1)(-393,520 + 65,271 - 9364) + (2)(-241,820 + 53,351 - 9904) \\
 &\quad + (7.52)(0 + 43,605 - 8669) - (1)(-74,850) - 0 - 0 \\
 &= -396,790 \text{ kJ/kmol of CH}_4
 \end{aligned}$$

That is, 396,790 kJ of heat is supplied to the combustion chamber for each kmol of methane burned. To supply heat at the required rate of 12,844 kJ/s, we must burn methane at a rate of

$$\dot{N}_{\text{CH}_4} = \frac{\dot{Q}}{Q} = \frac{12,844 \text{ kJ/s}}{396,790 \text{ kJ/kmol}} = 0.03237 \text{ kmolCH}_4/\text{s}$$

or,

$$\dot{m}_{\text{CH}_4} = M_{\text{CH}_4} \dot{N}_{\text{CH}_4} = (16 \text{ kg/kmol})(0.03237 \text{ kmolCH}_4/\text{s}) = \mathbf{0.5179 \text{ kg/s}}$$

Therefore, we must supply methane to the combustion chamber at a minimum rate 0.5179 kg/s in order to maintain the temperature of the combustion chamber above 1400 K.

K_p and Equilibrium Composition of Ideal Gases

16-1C They are

$$K_p = \frac{P_C^{v_C} P_D^{v_D}}{P_A^{v_A} P_B^{v_B}}, \quad K_p = e^{-\Delta G^*(T)/R_u T} \quad \text{and} \quad K_p = \frac{N_C^{v_C} N_D^{v_D}}{N_A^{v_A} N_B^{v_B}} \left(\frac{P}{N_{\text{total}}} \right)^{\Delta v}$$

where $\Delta v = v_C + v_D - v_A - v_B$. The first relation is useful in partial pressure calculations, the second in determining the K_p from gibbs functions, and the last one in equilibrium composition calculations.

16-2C (a) The equilibrium constant for the reaction $\text{CO} + \frac{1}{2} \text{O}_2 \Leftrightarrow \text{CO}_2$ can be expressed as

$$K_p = \frac{N_{\text{CO}_2}^{v_{\text{CO}_2}}}{N_{\text{CO}}^{v_{\text{CO}}} N_{\text{O}_2}^{v_{\text{O}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(v_{\text{CO}_2} - v_{\text{CO}} - v_{\text{O}_2})}$$

Judging from the values in Table A-28, the K_p value for this reaction decreases as temperature increases. That is, the indicated reaction will be less complete at higher temperatures. Therefore, the number of moles of CO_2 will decrease and the number moles of CO and O_2 will increase as the temperature increases.

(b) The value of the exponent in this case is $1 - 1 - 0.5 = -0.5$, which is negative. Thus as the pressure increases, the term in the brackets will decrease. The value of K_p depends on temperature only, and therefore it will not change with pressure. Then to keep the equation balanced, the number of moles of the products (CO_2) must increase, and the number of moles of the reactants (CO , O_2) must decrease.

16-3C (a) The equilibrium constant for the reaction $\text{N}_2 \Leftrightarrow 2\text{N}$ can be expressed as

$$K_p = \frac{N_{\text{N}}^{v_{\text{N}}}}{N_{\text{N}_2}^{v_{\text{N}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(v_{\text{N}} - v_{\text{N}_2})}$$

Judging from the values in Table A-28, the K_p value for this reaction increases as the temperature increases. That is, the indicated reaction will be more complete at higher temperatures. Therefore, the number of moles of N will increase and the number moles of N_2 will decrease as the temperature increases.

(b) The value of the exponent in this case is $2 - 1 = 1$, which is positive. Thus as the pressure increases, the term in the brackets also increases. The value of K_p depends on temperature only, and therefore it will not change with pressure. Then to keep the equation balanced, the number of moles of the products (N) must decrease, and the number of moles of the reactants (N_2) must increase.

16-4C The equilibrium constant for the reaction $\text{CO} + \frac{1}{2} \text{O}_2 \Leftrightarrow \text{CO}_2$ can be expressed as

$$K_p = \frac{N_{\text{CO}_2}^{v_{\text{CO}_2}}}{N_{\text{CO}}^{v_{\text{CO}}} N_{\text{O}_2}^{v_{\text{O}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(v_{\text{CO}_2} - v_{\text{CO}} - v_{\text{O}_2})}$$

Adding more N_2 (an inert gas) at constant temperature and pressure will increase N_{total} but will have no direct effect on other terms. Then to keep the equation balanced, the number of moles of the products (CO_2) must increase, and the number of moles of the reactants (CO , O_2) must decrease.

16-5C The values of the equilibrium constants for each dissociation reaction at 3000 K are, from Table A-28,

$$\text{N}_2 \Leftrightarrow 2\text{N} \Leftrightarrow \ln K_p = -22.359$$

$$\text{H}_2 \Leftrightarrow 2\text{H} \Leftrightarrow \ln K_p = -3.685 \quad (\text{greater than } -22.359)$$

Thus H_2 is more likely to dissociate than N_2 .

16-6C (a) This reaction is the reverse of the known H_2O reaction. The equilibrium constant is then

$$1/K_p$$

(b) This reaction is the reverse of the known H_2O reaction at a different pressure. Since pressure has no effect on the equilibrium constant,

$$1/K_p$$

(c) This reaction is the same as the known H_2O reaction multiplied by 3. The equilibrium constant is then

$$K_p^3$$

(d) This is the same as reaction (c) occurring at a different pressure. Since pressure has no effect on the equilibrium constant,

$$K_p^3$$

16-7C (a) K_{p1} , (b) $1/K_{p1}$, (c) K_{p1}^2 , (d) K_{p1} , (e) $1/K_{p1}^3$.

16-8C (a) K_{p1} , (b) $1/K_{p1}$, (c) K_{p1} , (d) K_{p1} , (e) K_{p1}^2 .

16-9C (a) No, because K_p depends on temperature only.

(b) Yes, because the total mixture pressure affects the mixture composition. The equilibrium constant for the reaction $\text{CO} + \frac{1}{2}\text{O}_2 \Leftrightarrow \text{CO}_2$ can be expressed as

$$K_p = \frac{N_{\text{CO}_2}^{v_{\text{CO}_2}}}{N_{\text{CO}}^{v_{\text{CO}}} N_{\text{O}_2}^{v_{\text{O}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(v_{\text{CO}_2} - v_{\text{CO}} - v_{\text{O}_2})}$$

The value of the exponent in this case is $1 - 1 - 0.5 = -0.5$, which is negative. Thus as the pressure increases, the term in the brackets will decrease. The value of K_p depends on temperature only, and therefore it will not change with pressure. Then to keep the equation balanced, the number of moles of the products (CO_2) must increase, and the number of moles of the reactants (CO , O_2) must decrease.

16-10 The mole fractions of the constituents of an ideal gas mixture is given. The Gibbs function of the N_2 in this mixture at the given mixture pressure and temperature is to be determined.

Analysis From Tables A-18 and A-26, at 1 atm pressure,

$$\begin{aligned}\bar{g}^*(600 \text{ K}, 1 \text{ atm}) &= \bar{g}_f^0 + \Delta[\bar{h}(T) - T\bar{s}^0(T)] \\ &= 0 + (17,563 - 600 \times 212.066) - (8669 - 298 \times 191.502) \\ &= -61,278 \text{ kJ/kmol}\end{aligned}$$

The partial pressure of N_2 is

$$P_{N_2} = y_{N_2}P = (0.30)(5 \text{ atm}) = 1.5 \text{ atm}$$

The Gibbs function of N_2 at 600 K and 1.5 atm is

$$\begin{aligned}\bar{g}(600 \text{ K}, 1.5 \text{ atm}) &= \bar{g}^*(600 \text{ K}, 1 \text{ atm}) + R_u T \ln P_{N_2} \\ &= -61,278 \text{ kJ/kmol} + (8.314 \text{ kJ/kmol})(600 \text{ K})\ln(1.5 \text{ atm}) \\ &= \mathbf{-59,260 \text{ kJ/kmol}}\end{aligned}$$

30% N_2
30% O_2
40% H_2O
5 atm
600 K

16-11 The temperature at which 0.2 percent of diatomic oxygen dissociates into monatomic oxygen at two pressures is to be determined.

Assumptions 1 The equilibrium composition consists of N_2 and N . **2** The constituents of the mixture are ideal gases.

Analysis (a) The stoichiometric and actual reactions can be written as

Stoichiometric: $N_2 \leftrightarrow 2N$ (thus $\nu_{N_2} = 1$ and $\nu_N = 2$)

Actual: $N_2 \leftrightarrow \underbrace{0.998N_2}_{\text{react.}} + \underbrace{0.004N}_{\text{prod.}}$

The equilibrium constant K_p can be determined from

$$K_p = \frac{N_N^{\nu_N}}{N_{N_2}^{\nu_{N_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{\nu_N - \nu_{N_2}} = \frac{0.004^2}{0.998} \left(\frac{1/101.325}{0.998 + 0.004} \right)^{2-1} = 1.579 \times 10^{-7}$$

and

$$\ln K_p = -15.66$$

From Table A-28, the temperature corresponding to this $\ln K_p$ value is

$$T = \mathbf{3628 \text{ K}}$$

(b) At 10 kPa,

$$K_p = \frac{N_N^{\nu_N}}{N_{N_2}^{\nu_{N_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{\nu_N - \nu_{N_2}} = \frac{0.004^2}{0.998} \left(\frac{10/101.325}{0.998 + 0.004} \right)^{2-1} = 1.579 \times 10^{-6}$$

$$\ln K_p = -13.36$$

From Table A-28, the temperature corresponding to this $\ln K_p$ value is

$$T = \mathbf{3909 \text{ K}}$$

$N_2 \leftrightarrow 2N$
0.2%
1 kPa

16-12 The temperature at which 5 percent of diatomic oxygen dissociates into monatomic oxygen at a specified pressure is to be determined.

Assumptions 1 The equilibrium composition consists of O_2 and O . **2** The constituents of the mixture are ideal gases.

Analysis The stoichiometric and actual reactions can be written as

Stoichiometric: $O_2 \leftrightarrow 2O$ (thus $\nu_{O_2} = 1$ and $\nu_O = 2$)

Actual: $O_2 \leftrightarrow \underbrace{0.95O_2}_{\text{react.}} + \underbrace{0.1O}_{\text{prod.}}$

The equilibrium constant K_p can be determined from

$$K_p = \frac{N_O^{\nu_O}}{N_{O_2}^{\nu_{O_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{\nu_O - \nu_{O_2}} = \frac{0.1^2}{0.95} \left(\frac{3}{0.95 + 0.1} \right)^{2-1} = 0.03008$$

From Table A-28, the temperature corresponding to this K_p value is

$$T = \mathbf{3133 \text{ K}}$$

16-13 The temperature at which 5 percent of diatomic oxygen dissociates into monatomic oxygen at a specified pressure is to be determined.

Assumptions 1 The equilibrium composition consists of O_2 and O . **2** The constituents of the mixture are ideal gases.

Analysis The stoichiometric and actual reactions can be written as

Stoichiometric: $O_2 \leftrightarrow 2O$ (thus $\nu_{O_2} = 1$ and $\nu_O = 2$)

Actual: $O_2 \leftrightarrow \underbrace{0.95O_2}_{\text{react.}} + \underbrace{0.1O}_{\text{prod.}}$

The equilibrium constant K_p can be determined from

$$K_p = \frac{N_O^{\nu_O}}{N_{O_2}^{\nu_{O_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{\nu_O - \nu_{O_2}} = \frac{0.1^2}{0.95} \left(\frac{6}{0.95 + 0.1} \right)^{2-1} = 0.06015$$

From Table A-28, the temperature corresponding to this K_p value is

$$T = \mathbf{3152 \text{ K}}$$

16-14 The equilibrium constant of the reaction $\text{H}_2\text{O} \leftrightarrow 1/2\text{H}_2 + \text{OH}$ is listed in Table A-28 at different temperatures. It is to be verified at a given temperature using Gibbs function data.

Analysis The K_p value of a reaction at a specified temperature can be determined from the Gibbs function data using

$$K_p = e^{-\Delta G^*(T)/R_u T} \quad \text{or} \quad \ln K_p = -\Delta G^*(T) / R_u T$$

where

$$\Delta G^*(T) = \nu_{\text{H}_2} \bar{g}_{\text{H}_2}^*(T) + \nu_{\text{OH}} \bar{g}_{\text{OH}}^*(T) - \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T)$$

At 298 K,

$$\Delta G^*(T) = 0.5(0) + 1(34,280) - 1(-228,590) = 262,870 \text{ kJ / kmol}$$

Substituting,

$$\ln K_p = -(262,870 \text{ kJ/kmol}) / [(8.314 \text{ kJ/kmol} \cdot \text{K})(298 \text{ K})] = -106.10$$

or

$$K_p = \mathbf{8.34 \times 10^{-47}} \quad (\text{Table A - 28: } \ln K_p = -106.21)$$

16-15 The equilibrium constant of the reaction $\text{H}_2\text{O} \Leftrightarrow \text{H}_2 + \frac{1}{2}\text{O}_2$ is to be determined using Gibbs function.

Analysis (a) The K_p value of a reaction at a specified temperature can be determined from the Gibbs function data using

$$K_p = e^{-\Delta G^*(T)/R_u T} \quad \text{or} \quad \ln K_p = -\Delta G^*(T) / R_u T$$

where

$$\Delta G^*(T) = \nu_{\text{H}_2} \bar{g}_{\text{H}_2}^*(T) + \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T) - \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T)$$

At 1000 K,

$$\begin{aligned} \Delta G^*(T) &= \nu_{\text{H}_2} \bar{g}_{\text{H}_2}^*(T) + \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T) - \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T) \\ &= \nu_{\text{H}_2} (\bar{h} - T\bar{s})_{\text{H}_2} + \nu_{\text{O}_2} (\bar{h} - T\bar{s})_{\text{O}_2} - \nu_{\text{H}_2\text{O}} (\bar{h} - T\bar{s})_{\text{H}_2\text{O}} \\ &= \nu_{\text{H}_2} [(\bar{h}_f + \bar{h}_{1000} - \bar{h}_{298}) - T\bar{s}]_{\text{H}_2} \\ &\quad + \nu_{\text{O}_2} [(\bar{h}_f + \bar{h}_{1000} - \bar{h}_{298}) - T\bar{s}]_{\text{O}_2} \\ &\quad - \nu_{\text{H}_2\text{O}} [(\bar{h}_f + \bar{h}_{1000} - \bar{h}_{298}) - T\bar{s}]_{\text{H}_2\text{O}} \\ &= 1 \times (0 + 29,154 - 8468 - 1000 \times 166.114) \\ &\quad + 0.5 \times (0 + 31,389 - 8682 - 1000 \times 243.471) \\ &\quad - 1 \times (-241,820 + 35,882 - 9904 - 1000 \times 232.597) \\ &= 192,629 \text{ kJ/kmol} \end{aligned}$$

Substituting,

$$\ln K_p = -\frac{192,629 \text{ kJ/kmol}}{(8.314 \text{ kJ/kmol} \cdot \text{K})(1000 \text{ K})} = \mathbf{-23.17}$$

or

$$K_p = \mathbf{8.66 \times 10^{-11}} \quad (\text{Table A - 28: } \ln K_p = -23.16)$$

At 2000 K,

$$\begin{aligned} \Delta G^*(T) &= \nu_{\text{H}_2} \bar{g}_{\text{H}_2}^*(T) + \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T) - \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T) \\ &= \nu_{\text{H}_2} (\bar{h} - T\bar{s})_{\text{H}_2} + \nu_{\text{O}_2} (\bar{h} - T\bar{s})_{\text{O}_2} - \nu_{\text{H}_2\text{O}} (\bar{h} - T\bar{s})_{\text{H}_2\text{O}} \\ &= \nu_{\text{H}_2} [(\bar{h}_f + \bar{h}_{2000} - \bar{h}_{298}) - T\bar{s}]_{\text{H}_2} \\ &\quad + \nu_{\text{O}_2} [(\bar{h}_f + \bar{h}_{2000} - \bar{h}_{298}) - T\bar{s}]_{\text{O}_2} \\ &\quad - \nu_{\text{H}_2\text{O}} [(\bar{h}_f + \bar{h}_{2000} - \bar{h}_{298}) - T\bar{s}]_{\text{H}_2\text{O}} \\ &= 1 \times (0 + 61,400 - 8468 - 2000 \times 188.297) \\ &\quad + 0.5 \times (0 + 67,881 - 8682 - 2000 \times 268.655) \\ &\quad - 1 \times (-241,820 + 82,593 - 9904 - 2000 \times 264.571) \\ &= 135,556 \text{ kJ/kmol} \end{aligned}$$

Substituting,

$$\ln K_p = -(135,556 \text{ kJ/kmol}) / [(8.314 \text{ kJ/kmol} \cdot \text{K})(2000 \text{ K})] = \mathbf{-8.15}$$

or

$$K_p = \mathbf{2.88 \times 10^{-4}} \quad (\text{Table A - 28: } \ln K_p = -8.15)$$

16-16 The reaction $C + O_2 \rightleftharpoons CO_2$ is considered. The mole fraction of the carbon dioxide produced when this reaction occurs at 1 atm and 3800 K are to be determined.

Assumptions 1 The equilibrium composition consists of CO_2 , C and O_2 . **2** The constituents of the mixture are ideal gases.

Analysis The stoichiometric and actual reactions in this case are

Stoichiometric: $C + O_2 \rightleftharpoons CO_2$ (thus $\nu_C = 1$, $\nu_{O_2} = 1$, and $\nu_{CO_2} = 1$)

Actual: $C + O_2 \longrightarrow \underbrace{x C + y O_2}_{\text{react.}} + \underbrace{z CO_2}_{\text{products}}$

C balance: $1 = x + z \longrightarrow z = 1 - x$

O balance: $2 = 2y + 2z \longrightarrow y = 1 - z = 1 - (1 - x) = x$

Total number of moles: $N_{\text{total}} = x + y + z = 1 + x$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{CO_2}^{\nu_{CO_2}}}{N_C^{\nu_C} N_{O_2}^{\nu_{O_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{CO_2} - \nu_C - \nu_{O_2})}$$

From the problem statement at 3800 K, $\ln K_p = -0.461$. Then,

$$K_p = \exp(-0.461) = 0.6307$$

Substituting,

$$0.6307 = \frac{(1-x)}{(x)(x)} \left(\frac{1}{1+x} \right)^{1-1-1}$$

Solving for x ,

$$x = 0.7831$$

Then,

$$y = x = 0.7831$$

$$z = 1 - x = 0.2169$$

Therefore, the equilibrium composition of the mixture at 3800 K and 1 atm is

The mole fraction of carbon dioxide is

$$y_{CO_2} = \frac{N_{CO_2}}{N_{\text{total}}} = \frac{0.2169}{1 + 0.7831} = \mathbf{0.1216}$$

16-17 A gaseous mixture consisting of methane and carbon dioxide is heated. The equilibrium composition (by mole fraction) of the resulting mixture is to be determined.

Assumptions 1 The equilibrium composition consists of CH_4 , C, H_2 , and CO_2 . **2** The constituents of the mixture are ideal gases.

Analysis The stoichiometric and actual reactions in this case are

Stoichiometric: $\text{CH}_4 \leftrightarrow \text{C} + 2\text{H}_2$ (thus $\nu_{\text{CH}_4} = 1$, $\nu_{\text{C}} = 1$, and $\nu_{\text{H}_2} = 2$)

Actual: $0.3\text{CH}_4 + 0.7\text{CO}_2 \longrightarrow \underbrace{x\text{CH}_4}_{\text{react.}} + \underbrace{y\text{C} + z\text{H}_2}_{\text{products}} + \underbrace{0.7\text{CO}_2}_{\text{inert}}$

C balance: $0.3 = x + y \longrightarrow y = 0.3 - x$

H balance: $1.2 = 4x + 2z \longrightarrow z = 0.6 - 2x$

Total number of moles: $N_{\text{total}} = x + y + z + 1 = 1.6 - 2x$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{\text{CH}_4}^{\nu_{\text{CH}_4}}}{N_{\text{C}}^{\nu_{\text{C}}} N_{\text{H}_2}^{\nu_{\text{H}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{\nu_{\text{CH}_4} - \nu_{\text{C}} - \nu_{\text{H}_2}}$$

From the problem statement at 1200 K, $\ln K_p = 4.147$. Then,

$$K_p = \exp(4.147) = 63.244$$

For the reverse reaction that we consider,

$$K_p = 1/63.244 = 0.01581$$

Substituting,

$$0.01581 = \frac{x}{(0.3 - x)(0.6 - 2x)^2} \left(\frac{1}{1.6 - 2x} \right)^{1-1-2}$$

Solving for x ,

$$x = 0.0006637$$

Then,

$$y = 0.3 - x = 0.2993$$

$$z = 0.6 - 2x = 0.5987$$

Therefore, the equilibrium composition of the mixture at 1200 K and 1 atm is

The mole fractions are

$$y_{\text{CH}_4} = \frac{N_{\text{CH}_4}}{N_{\text{total}}} = \frac{0.0006637}{1.6 - 2 \times 0.0006637} = \frac{0.0006637}{1.599} = \mathbf{0.000415}$$

$$y_{\text{C}} = \frac{N_{\text{C}}}{N_{\text{total}}} = \frac{0.2993}{1.599} = \mathbf{0.1872}$$

$$y_{\text{H}_2} = \frac{N_{\text{H}_2}}{N_{\text{total}}} = \frac{0.5987}{1.599} = \mathbf{0.3745}$$

$$y_{\text{CO}_2} = \frac{N_{\text{CO}_2}}{N_{\text{total}}} = \frac{0.7}{1.599} = \mathbf{0.4379}$$

16-18 The dissociation reaction $\text{CO}_2 \Leftrightarrow \text{CO} + \text{O}$ is considered. The composition of the products at given pressure and temperature is to be determined.

Assumptions 1 The equilibrium composition consists of CO_2 , CO , and O . **2** The constituents of the mixture are ideal gases.

Analysis For the stoichiometric reaction $\text{CO}_2 \Leftrightarrow \text{CO} + \frac{1}{2}\text{O}_2$, from Table A-28, at 2500 K

$$\ln K_p = -3.331$$

For the oxygen dissociation reaction $0.5\text{O}_2 \Leftrightarrow \text{O}$, from Table A-28, at 2500 K,

$$\ln K_p = -8.509 / 2 = -4.255$$

For the desired stoichiometric reaction $\text{CO}_2 \Leftrightarrow \text{CO} + \text{O}$ (thus $\nu_{\text{CO}_2} = 1$, $\nu_{\text{CO}} = 1$ and $\nu_{\text{O}} = 1$),

$$\ln K_p = -3.331 - 4.255 = -7.586$$

and

$$K_p = \exp(-7.586) = 0.0005075$$

C balance: $1 = x + y \longrightarrow y = 1 - x$

O balance: $2 = 2x + y + z \longrightarrow z = 1 - x$

Total number of moles: $N_{\text{total}} = x + y + z = 2 - x$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{\text{CO}}^{\nu_{\text{CO}}} N_{\text{O}}^{\nu_{\text{O}}}}{N_{\text{CO}_2}^{\nu_{\text{CO}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{\nu_{\text{CO}} + \nu_{\text{O}} - \nu_{\text{CO}_2}}$$

Substituting,

$$0.0005075 = \frac{(1-x)(1-x)}{x} \left(\frac{1}{2-x} \right)^{1+1-1}$$

Solving for x ,

$$x = 0.9775$$

Then,

$$y = 1 - x = 0.0225$$

$$z = 1 - x = 0.0225$$

Therefore, the equilibrium composition of the mixture at 2500 K and 1 atm is

16-19 The reaction $\text{N}_2 + \text{O}_2 \rightleftharpoons 2\text{NO}$ is considered. The equilibrium mole fraction of NO at 1800 K and 1 atm is to be determined.

Assumptions 1 The equilibrium composition consists of N_2 , O_2 , and NO. **2** The constituents of the mixture are ideal gases.

Analysis The stoichiometric and actual reactions in this case are

Stoichiometric: $\text{N}_2 + \text{O}_2 \rightleftharpoons 2\text{NO}$ (thus $\nu_{\text{N}_2} = 1$, $\nu_{\text{O}_2} = 1$, and $\nu_{\text{NO}} = 2$)

Actual: $\text{N}_2 + \text{O}_2 \longrightarrow \underbrace{x\text{N}_2 + y\text{O}_2}_{\text{react.}} + \underbrace{z\text{NO}}_{\text{products}}$

N balance: $2 = 2x + z \longrightarrow z = 2 - 2x$

O balance: $2 = 2y + z \longrightarrow y = x$

Total number of moles: $N_{\text{total}} = x + y + z = 2$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{\text{NO}}^{\nu_{\text{NO}}}}{N_{\text{N}_2}^{\nu_{\text{N}_2}} N_{\text{O}_2}^{\nu_{\text{O}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{NO}} - \nu_{\text{N}_2} - \nu_{\text{O}_2})}$$

From Table A-28, at 1800 K, $\ln K_p = -4.536$. Since the stoichiometric reaction being considered is double this reaction,

$$K_p = \exp(-2 \times 4.536) = 1.148 \times 10^{-4}$$

Substituting,

$$1.148 \times 10^{-4} = \frac{(2 - 2x)^2}{x^2} \left(\frac{1}{2} \right)^{2-1-1}$$

Solving for x ,

$$x = 0.9947$$

Then,

$$y = x = 0.9947$$

$$z = 2 - 2x = 0.010659$$

Therefore, the equilibrium composition of the mixture at 1800 K and 1 atm is

$$0.9947 \text{N}_2 + 0.9947 \text{O}_2 + 0.010659 \text{NO}$$

The mole fraction of NO is then

$$y_{\text{NO}} = \frac{N_{\text{NO}}}{N_{\text{total}}} = \frac{0.010659}{2} = \mathbf{0.00533}$$

16-20E The equilibrium constant of the reaction $\text{H}_2 + 1/2\text{O}_2 \leftrightarrow \text{H}_2\text{O}$ is listed in Table A-28 at different temperatures. The data are to be verified at two temperatures using Gibbs function data.

Analysis (a) The K_p value of a reaction at a specified temperature can be determined from the Gibbs function data using

$$K_p = e^{-\Delta G^*(T)/R_u T} \quad \text{or} \quad \ln K_p = -\Delta G^*(T) / R_u T$$

where

$$\Delta G^*(T) = \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T) - \nu_{\text{H}_2} \bar{g}_{\text{H}_2}^*(T) - \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T)$$

At 537 R,

$$\Delta G^*(T) = 1(-98,350) - 1(0) - 0.5(0) = -98,350 \text{ Btu / lbmol}$$

Substituting,

$$\ln K_p = -(-98,350 \text{ Btu / lbmol}) / [(1.986 \text{ Btu / lbmol} \cdot \text{R})(537 \text{ R})] = 92.22$$

or

$$K_p = \mathbf{1.12 \times 10^{40}} \quad (\text{Table A - 28: } \ln K_p = 92.21)$$

(b) At 3240 R,

$$\begin{aligned} \Delta G^*(T) &= \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T) - \nu_{\text{H}_2} \bar{g}_{\text{H}_2}^*(T) - \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T) \\ &= \nu_{\text{H}_2\text{O}} (\bar{h} - T\bar{s})_{\text{H}_2\text{O}} - \nu_{\text{H}_2} (\bar{h} - T\bar{s})_{\text{H}_2} - \nu_{\text{O}_2} (\bar{h} - T\bar{s})_{\text{O}_2} \\ &= \nu_{\text{H}_2\text{O}} [(\bar{h}_f + \bar{h}_{4320} - \bar{h}_{537}) - T\bar{s}]_{\text{H}_2\text{O}} \\ &\quad - \nu_{\text{H}_2} [(\bar{h}_f + \bar{h}_{4320} - \bar{h}_{298}) - T\bar{s}]_{\text{H}_2} \\ &\quad - \nu_{\text{O}_2} [(\bar{h}_f + \bar{h}_{4320} - \bar{h}_{298}) - T\bar{s}]_{\text{O}_2} \\ &= 1 \times (-104,040 + 31,205 - 4258 - 3240 \times 61.948) \\ &\quad - 1 \times (0 + 23,485 - 3640.3 - 3240 \times 44.125) \\ &\quad - 0.5 \times (0 + 25,972 - 3725.1 - 3240 \times 63.224) \\ &= -63,385 \text{ Btu/lbmol} \end{aligned}$$

Substituting,

$$\ln K_p = -\frac{-63,385 \text{ Btu/lbmol}}{(1.986 \text{ Btu/lbmolR})(3240 \text{ R})} = 9.851$$

or

$$K_p = \mathbf{1.90 \times 10^4} \quad (\text{Table A - 28: } \ln K_p = 9.826)$$

Discussion Solving this problem using EES with the built-in ideal gas properties give $K_p = 1.04 \times 10^{40}$ for part (a) and $K_p = 18,692$ for part (b).

16-21 The equilibrium constant of the reaction $\text{CO} + 1/2\text{O}_2 \leftrightarrow \text{CO}_2$ at 298 K and 2000 K are to be determined, and compared with the values listed in Table A-28.

Analysis (a) The K_p value of a reaction at a specified temperature can be determined from the Gibbs function data using

$$K_p = e^{-\Delta G^*(T)/R_u T} \quad \text{or} \quad \ln K_p = -\Delta G^*(T) / R_u T$$

where

$$\Delta G^*(T) = \nu_{\text{CO}_2} \bar{g}_{\text{CO}_2}^*(T) - \nu_{\text{CO}} \bar{g}_{\text{CO}}^*(T) - \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T)$$

At 298 K,

$$\Delta G^*(T) = 1(-394,360) - 1(-137,150) - 0.5(0) = -257,210 \text{ kJ/kmol}$$

where the Gibbs functions are obtained from Table A-26. Substituting,

$$\ln K_p = -\frac{(-257,210 \text{ kJ/kmol})}{(8.314 \text{ kJ/kmol} \cdot \text{K})(298 \text{ K})} = \mathbf{103.81}$$

From Table A-28: $\ln K_p = \mathbf{103.76}$

(b) At 2000 K,

$$\begin{aligned} \Delta G^*(T) &= \nu_{\text{CO}_2} \bar{g}_{\text{CO}_2}^*(T) - \nu_{\text{CO}} \bar{g}_{\text{CO}}^*(T) - \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T) \\ &= \nu_{\text{CO}_2} (\bar{h} - T\bar{s})_{\text{CO}_2} - \nu_{\text{CO}} (\bar{h} - T\bar{s})_{\text{CO}} - \nu_{\text{O}_2} (\bar{h} - T\bar{s})_{\text{O}_2} \\ &= 1[(-302,128) - (2000)(309.00)] - 1[(-53,826) - (2000)(258.48)] - 0.5[(59,193) - (2000)(268.53)] \\ &= -110,409 \text{ kJ/kmol} \end{aligned}$$

The enthalpies at 2000 K and entropies at 2000 K and 101.3 kPa (1 atm) are obtained from EES. Substituting,

$$\ln K_p = -\frac{(-110,409 \text{ kJ/kmol})}{(8.314 \text{ kJ/kmol} \cdot \text{K})(2000 \text{ K})} = \mathbf{6.64}$$

From Table A-28:

$$\ln K_p = \mathbf{6.635}$$

16-22  The effect of varying the percent excess air during the steady-flow combustion of hydrogen is to be studied.

Analysis The combustion equation of hydrogen with stoichiometric amount of air is

For the incomplete combustion with 100% excess air, the combustion equation is

The coefficients are to be determined from the mass balances

Hydrogen balance: $2 = 0.97 \times 2 + a \times 2 \longrightarrow a = 0.03$

Oxygen balance: $(1 + Ex) \times 0.5 \times 2 = 0.97 + b \times 2$

Nitrogen balance: $(1 + Ex) \times 0.5 \times 3.76 \times 2 = c \times 2$

Solving the above equations, we find the coefficients ($Ex = 1$, $a = 0.03$, $b = 0.515$, $c = 3.76$) and write the balanced reaction equation as

Total moles of products at equilibrium are

$$N_{\text{tot}} = 0.97 + 0.03 + 0.515 + 3.76 = 5.275$$

The assumed equilibrium reaction is

The K_p value of a reaction at a specified temperature can be determined from the Gibbs function data using

$$K_p = e^{-\Delta G^*(T)/R_u T} \quad \text{or} \quad \ln K_p = -\Delta G^*(T) / R_u T$$

where

$$\Delta G^*(T) = \nu_{\text{H}_2} \bar{g}_{\text{H}_2}^*(T_{\text{prod}}) + \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T_{\text{prod}}) - \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T_{\text{prod}})$$

and the Gibbs functions are defined as

$$\bar{g}_{\text{H}_2}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}} \bar{s})_{\text{H}_2}$$

$$\bar{g}_{\text{O}_2}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}} \bar{s})_{\text{O}_2}$$

$$\bar{g}_{\text{H}_2\text{O}}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}} \bar{s})_{\text{H}_2\text{O}}$$

The equilibrium constant is also given by

$$K_p = \left(\frac{P}{N_{\text{tot}}} \right)^{1+0.5-1} \frac{ab^{0.5}}{0.97^1} = \left(\frac{1}{5.275} \right)^{0.5} \frac{(0.03)(0.515)^{0.5}}{0.97} = 0.009664$$

and $\ln K_p = \ln(0.009664) = -4.647$

The corresponding temperature is obtained solving the above equations using EES to be

$$T_{\text{prod}} = \mathbf{2600\text{K}}$$

This is the temperature at which 97 percent of H_2 will burn into H_2O . The copy of EES solution is given next.

16-23 The equilibrium constant of the reaction $\text{CH}_4 + 2\text{O}_2 \leftrightarrow \text{CO}_2 + 2\text{H}_2\text{O}$ at 25°C is to be determined.

Analysis The K_p value of a reaction at a specified temperature can be determined from the Gibbs function data using

$$K_p = e^{-\Delta G^*(T)/R_u T} \quad \text{or} \quad \ln K_p = -\Delta G^*(T) / R_u T$$

where

$$\Delta G^*(T) = \nu_{\text{CO}_2} \bar{g}_{\text{CO}_2}^*(T) + \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T) - \nu_{\text{CH}_4} \bar{g}_{\text{CH}_4}^*(T) - \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T)$$

25°C

At 25°C ,

$$\Delta G^*(T) = 1(-394,360) + 2(-228,590) - 1(-50,790) - 2(0) = -800,750 \text{ kJ / kmol}$$

Substituting,

$$\ln K_p = -(-800,750 \text{ kJ/kmol}) / [(8.314 \text{ kJ/kmol} \cdot \text{K})(298 \text{ K})] = 323.04$$

or $K_p = \mathbf{1.96 \times 10^{140}}$

16-24 The equilibrium constant of the reaction $\text{CO}_2 \leftrightarrow \text{CO} + 1/2\text{O}_2$ is listed in Table A-28 at different temperatures. It is to be verified using Gibbs function data.

Analysis (a) The K_p value of a reaction at a specified temperature can be determined from the Gibbs function data using

$$K_p = e^{-\Delta G^*(T)/R_u T} \quad \text{or} \quad \ln K_p = -\Delta G^*(T) / R_u T$$

where $\Delta G^*(T) = \nu_{\text{CO}} \bar{g}_{\text{CO}}^*(T) + \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T) - \nu_{\text{CO}_2} \bar{g}_{\text{CO}_2}^*(T)$

At 298 K,

$$\Delta G^*(T) = 1(-137,150) + 0.5(0) - 1(-394,360) = 257,210 \text{ kJ/kmol}$$

Substituting,

$$\ln K_p = -(257,210 \text{ kJ/kmol}) / [(8.314 \text{ kJ/kmol} \cdot \text{K})(298 \text{ K})] = -103.81$$

or $K_p = \mathbf{8.24 \times 10^{-46}}$ (Table A - 28: $\ln K_p = -103.76$)

(b) At 1800 K,

$$\begin{aligned} \Delta G^*(T) &= \nu_{\text{CO}} \bar{g}_{\text{CO}}^*(T) + \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T) - \nu_{\text{CO}_2} \bar{g}_{\text{CO}_2}^*(T) \\ &= \nu_{\text{CO}} (\bar{h} - T\bar{s})_{\text{CO}} + \nu_{\text{O}_2} (\bar{h} - T\bar{s})_{\text{O}_2} - \nu_{\text{CO}_2} (\bar{h} - T\bar{s})_{\text{CO}_2} \\ &= \nu_{\text{CO}} [(\bar{h}_f + \bar{h}_{1800} - \bar{h}_{298}) - T\bar{s}]_{\text{CO}} \\ &\quad + \nu_{\text{O}_2} [(\bar{h}_f + \bar{h}_{1800} - \bar{h}_{298}) - T\bar{s}]_{\text{O}_2} \\ &\quad - \nu_{\text{CO}_2} [(\bar{h}_f + \bar{h}_{1800} - \bar{h}_{298}) - T\bar{s}]_{\text{CO}_2} \\ &= 1 \times (-110,530 + 58,191 - 8669 - 1800 \times 254.797) \\ &\quad + 0.5 \times (0 + 60,371 - 8682 - 1800 \times 264.701) \\ &\quad - 1 \times (-393,520 + 88,806 - 9364 - 1800 \times 302.884) \\ &= 127,240.2 \text{ kJ/kmol} \end{aligned}$$

Substituting, $\ln K_p = -(127,240.2 \text{ kJ/kmol}) / [(8.314 \text{ kJ/kmol} \cdot \text{K})(1800 \text{ K})] = -8.502$

or $K_p = \mathbf{2.03 \times 10^{-4}}$ (Table A - 28: $\ln K_p = -8.497$)

16-25  Carbon monoxide is burned with 100 percent excess air. The temperature at which 97 percent of CO burn to CO₂ is to be determined.

Assumptions 1 The equilibrium composition consists of CO₂, CO, O₂, and N₂. **2** The constituents of the mixture are ideal gases.

Analysis Assuming N₂ to remain as an inert gas, the stoichiometric and actual reactions can be written as

Stoichiometric: $\text{CO} + \frac{1}{2}\text{O}_2 \leftrightarrow \text{CO}_2$ (thus $\nu_{\text{CO}_2} = 1$, $\nu_{\text{CO}} = 1$, and $\nu_{\text{O}_2} = \frac{1}{2}$)

Actual: $\text{CO} + 1(\text{O}_2 + 3.76\text{N}_2) \longrightarrow \underbrace{0.97\text{CO}_2}_{\text{product}} + \underbrace{0.03\text{CO} + 0.515\text{O}_2}_{\text{reactants}} + \underbrace{3.76\text{N}_2}_{\text{inert}}$

The equilibrium constant K_p can be determined from

$$K_p = \frac{N_{\text{CO}_2}^{\nu_{\text{CO}_2}}}{N_{\text{CO}}^{\nu_{\text{CO}}} N_{\text{O}_2}^{\nu_{\text{O}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{CO}_2} - \nu_{\text{CO}} - \nu_{\text{O}_2})}$$

$$= \frac{0.97}{0.03 \times 0.515^{0.5}} \left(\frac{1}{0.97 + 0.03 + 0.515 + 3.76} \right)^{1-1.5}$$

$$= 103.5$$

and

$$\ln K_p = 4.639$$

From Table A-28, the temperature corresponding to this K_p value is $T = 2276 \text{ K}$

16-26 Problem 16-25 is reconsidered. The effect of varying the percent excess air during the steady-flow process from 0 to 200 percent on the temperature at which 97 percent of CO burn into CO₂ is to be studied.

Analysis The problem is solved using EES, and the solution is given below.

"To solve this problem, we need to give EES a guess value for T_{prop} other than the default value of 1. Set the guess value of T_{prod} to 1000 K by selecting Variable Information in the Options menu. Then press F2 or click the Calculator icon."

16-27E Carbon monoxide is burned with 100 percent excess air. The temperature at which 97 percent of CO burn to CO₂ is to be determined.

Assumptions 1 The equilibrium composition consists of CO₂, CO, O₂, and N₂. **2** The constituents of the mixture are ideal gases.

Analysis Assuming N₂ to remain as an inert gas, the stoichiometric and actual reactions can be written as

Stoichiometric: $\text{CO} + \frac{1}{2}\text{O}_2 \leftrightarrow \text{CO}_2$ (thus $\nu_{\text{CO}_2} = 1$, $\nu_{\text{CO}} = 1$, and $\nu_{\text{O}_2} = \frac{1}{2}$)

Actual: $\text{CO} + 1(\text{O}_2 + 3.76\text{N}_2) \longrightarrow \underbrace{0.97\text{CO}_2}_{\text{product}} + \underbrace{0.03\text{CO} + 0.515\text{O}_2}_{\text{reactants}} + \underbrace{3.76\text{N}_2}_{\text{inert}}$

The equilibrium constant K_p can be determined from

$$K_p = \frac{N_{\text{CO}_2}^{\nu_{\text{CO}_2}}}{N_{\text{CO}}^{\nu_{\text{CO}}} N_{\text{O}_2}^{\nu_{\text{O}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{CO}_2} - \nu_{\text{CO}} - \nu_{\text{O}_2})}$$

$$= \frac{0.97}{0.03 \times 0.515^{0.5}} \left(\frac{1}{0.97 + 0.03 + 0.515 + 3.76} \right)^{1-1.5}$$

$$= 103.5$$

and

$$\ln K_p = 4.639$$

From Table A-28, the temperature corresponding to this K_p value is $T = 2276 \text{ K} = \mathbf{4097 \text{ R}}$

16-28 Air is heated to a high temperature. The equilibrium composition at that temperature is to be determined.

Assumptions 1 The equilibrium composition consists of N_2 , O_2 , and NO . **2** The constituents of the mixture are ideal gases.

Analysis The stoichiometric and actual reactions in this case are

Stoichiometric: $\frac{1}{2} N_2 + \frac{1}{2} O_2 \Leftrightarrow NO$ (thus $\nu_{NO} = 1$, $\nu_{N_2} = \frac{1}{2}$, and $\nu_{O_2} = \frac{1}{2}$)

Actual: $3.76 N_2 + O_2 \longrightarrow \underbrace{x NO}_{\text{prod.}} + \underbrace{y N_2 + z O_2}_{\text{reactants}}$

N balance: $7.52 = x + 2y$ or $y = 3.76 - 0.5x$

O balance: $2 = x + 2z$ or $z = 1 - 0.5x$

Total number of moles: $N_{\text{total}} = x + y + z = x + 4.76 - x = 4.76$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{NO}^{\nu_{NO}}}{N_{N_2}^{\nu_{N_2}} N_{O_2}^{\nu_{O_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{NO} - \nu_{N_2} - \nu_{O_2})}$$

From Table A-28, $\ln K_p = -3.931$ at 2000 K. Thus $K_p = 0.01962$. Substituting,

$$0.01962 = \frac{x}{(3.76 - 0.5x)^{0.5} (1 - 0.5x)^{0.5}} \left(\frac{2}{4.76} \right)^{1-1}$$

Solving for x ,

$$x = 0.0376$$

Then,

$$y = 3.76 - 0.5x = 3.7412$$

$$z = 1 - 0.5x = 0.9812$$

Therefore, the equilibrium composition of the mixture at 2000 K and 2 atm is

The equilibrium constant for the reactions $O_2 \Leftrightarrow 2O$ ($\ln K_p = -14.622$) and $N_2 \Leftrightarrow 2N$ ($\ln K_p = -41.645$) are much smaller than that of the specified reaction ($\ln K_p = -3.931$). Therefore, it is realistic to assume that no monatomic oxygen or nitrogen will be present in the equilibrium mixture. Also the equilibrium composition in this case is independent of pressure since $\Delta\nu = 1 - 0.5 - 0.5 = 0$.

16-29 Hydrogen is heated to a high temperature at a constant pressure. The percentage of H_2 that will dissociate into H is to be determined.

Assumptions 1 The equilibrium composition consists of H_2 and H. **2** The constituents of the mixture are ideal gases.

Analysis The stoichiometric and actual reactions can be written as

Stoichiometric: $H_2 \leftrightarrow 2H$ (thus $\nu_{H_2} = 1$ and $\nu_H = 2$)

Actual: $H_2 \longrightarrow \underbrace{xH_2}_{\text{react.}} + \underbrace{yH}_{\text{prod.}}$

H balance: $2 = 2x + y$ or $y = 2 - 2x$

Total number of moles: $N_{\text{total}} = x + y = x + 2 - 2x = 2 - x$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_H^{\nu_H}}{N_{H_2}^{\nu_{H_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{\nu_H - \nu_{H_2}}$$

From Table A-28, $\ln K_p = 0.202$ at 3800 K. Thus $K_p = 1.224$. Substituting,

$$1.224 = \frac{(2 - 2x)^2}{x} \left(\frac{5}{2 - x} \right)^{2-1}$$

Solving for x ,

$$x = 0.7599$$

Thus the percentage of H_2 which dissociates to H at 3200 K and 5 atm is

$$1 - 0.7599 = 0.240 \quad \text{or} \quad \mathbf{24.0\%}$$

16-30 Carbon dioxide is heated to a high temperature at a constant pressure. The percentage of CO_2 that will dissociate into CO and O_2 is to be determined.

Assumptions 1 The equilibrium composition consists of CO_2 , CO , and O_2 . **2** The constituents of the mixture are ideal gases.

Analysis The stoichiometric and actual reactions in this case are

C balance: $1 = x + y \longrightarrow y = 1 - x$

O balance: $2 = 2x + y + 2z \longrightarrow z = 0.5 - 0.5x$

Total number of moles: $N_{\text{total}} = x + y + z = 1.5 - 0.5x$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{\text{CO}}^{\nu_{\text{CO}}} N_{\text{O}_2}^{\nu_{\text{O}_2}}}{N_{\text{CO}_2}^{\nu_{\text{CO}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{CO}} + \nu_{\text{O}_2} - \nu_{\text{CO}_2})}$$

From Table A-28, $\ln K_p = -3.860$ at 2400 K. Thus $K_p = 0.02107$ Substituting,

$$0.02107 = \frac{(1-x)(0.5-0.5x)^{1/2}}{x} \left(\frac{3}{1.5-0.5x} \right)^{1.5-1}$$

Solving for x ,

$$x = 0.936$$

Thus the percentage of CO_2 which dissociates into CO and O_2 is

$$1 - 0.936 = 0.064 \text{ or } \mathbf{6.4\%}$$

16-31 A mixture of CO and O₂ is heated to a high temperature at a constant pressure. The equilibrium composition is to be determined.

Assumptions 1 The equilibrium composition consists of CO₂, CO, and O₂. **2** The constituents of the mixture are ideal gases.

Analysis The stoichiometric and actual reactions in this case are

Stoichiometric: $\text{CO}_2 \Leftrightarrow \text{CO} + \frac{1}{2}\text{O}_2$ (thus $\nu_{\text{CO}_2} = 1$, $\nu_{\text{CO}} = 1$, and $\nu_{\text{O}_2} = \frac{1}{2}$)

Actual: $\text{CO} + 3\text{O}_2 \longrightarrow \underbrace{x\text{CO}_2}_{\text{react.}} + \underbrace{y\text{CO} + z\text{O}_2}_{\text{products}}$

C balance: $1 = x + y \longrightarrow y = 1 - x$

O balance: $7 = 2x + y + 2z$ or $z = 3 - 0.5x$

Total number of moles: $N_{\text{total}} = x + y + z = 4 - 0.5x$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{\text{CO}_2}^{\nu_{\text{CO}_2}}}{N_{\text{CO}}^{\nu_{\text{CO}}} N_{\text{O}_2}^{\nu_{\text{O}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{CO}_2} - \nu_{\text{CO}} - \nu_{\text{O}_2})}$$

From Table A-28, $\ln K_p = 5.120$ at 2200 K. Thus $K_p = 167.34$. Substituting,

$$167.34 = \frac{x}{(1-x)(3-0.5x)^{0.5}} \left(\frac{2}{4-0.5x} \right)^{1-1.5}$$

Solving for x ,

$$x = 0.995$$

Then,

$$y = 1 - x = 0.005$$

$$z = 3 - 0.5x = 2.5025$$

Therefore, the equilibrium composition of the mixture at 2200 K and 2 atm is

1 CO
3 O ₂
2200 K
2 atm

16-32 A mixture of N_2 , O_2 , and Ar is heated to a high temperature at a constant pressure. The equilibrium composition is to be determined.

Assumptions 1 The equilibrium composition consists of N_2 , O_2 , Ar, and NO. **2** The constituents of the mixture are ideal gases.

Analysis The stoichiometric and actual reactions in this case are

3 N_2
1 O_2
0.1 Ar
2400 K
10 atm

N balance: $6 = x + 2y \longrightarrow y = 3 - 0.5x$

O balance: $2 = x + 2z \longrightarrow z = 1 - 0.5x$

Total number of moles: $N_{\text{total}} = x + y + z + 0.1 = 4.1$

The equilibrium constant relation becomes,

$$K_p = \frac{N_{NO}^{\nu_{NO}}}{N_{N_2}^{\nu_{N_2}} N_{O_2}^{\nu_{O_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{NO} - \nu_{N_2} - \nu_{O_2})} = \frac{x}{y^{0.5} z^{0.5}} \left(\frac{P}{N_{\text{total}}} \right)^{1-0.5-0.5}$$

From Table A-28, $\ln K_p = -3.019$ at 2400 K. Thus $K_p = 0.04885$. Substituting,

$$0.04885 = \frac{x}{(3 - 0.5x)^{0.5} (1 - 0.5x)^{0.5}} \times 1$$

Solving for x ,

$$x = 0.0823$$

Then,

$$y = 3 - 0.5x = 2.9589$$

$$z = 1 - 0.5x = 0.9589$$

Therefore, the equilibrium composition of the mixture at 2400 K and 10 atm is

16-33 The mole fraction of sodium that ionizes according to the reaction $\text{Na} \leftrightarrow \text{Na}^+ + \text{e}^-$ at 2000 K and 0.8 atm is to be determined.

Assumptions All components behave as ideal gases.

Analysis The stoichiometric and actual reactions can be written as

Stoichiometric: $\text{Na} \leftrightarrow \text{Na}^+ + \text{e}^-$ (thus $\nu_{\text{Na}} = 1$, $\nu_{\text{Na}^+} = 1$ and $\nu_{\text{e}^-} = 1$)

Actual: $\text{Na} \longrightarrow \underbrace{x\text{Na}}_{\text{react.}} + \underbrace{y\text{Na}^+ + y\text{e}^-}_{\text{products}}$

Na balance: $1 = x + y$ or $y = 1 - x$

Total number of moles: $N_{\text{total}} = x + 2y = 2 - x$

The equilibrium constant relation becomes,

$$K_p = \frac{N_{\text{Na}^+}^{\nu_{\text{Na}^+}} N_{\text{e}^-}^{\nu_{\text{e}^-}}}{N_{\text{Na}}^{\nu_{\text{Na}}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{Na}^+} + \nu_{\text{e}^-} - \nu_{\text{Na}})} = \frac{y^2}{x} \left(\frac{P}{N_{\text{total}}} \right)^{1+1-1}$$

Substituting,

$$0.668 = \frac{(1-x)^2}{x} \left(\frac{0.8}{2-x} \right)$$

Solving for x ,

$$x = 0.3254$$

Thus the fraction of Na which dissociates into Na^+ and e^- is

$$1 - 0.3254 = 0.6746 \text{ or } \mathbf{67.5\%}$$

16-34E A steady-flow combustion chamber is supplied with CO and O₂. The equilibrium composition of product gases and the rate of heat transfer from the combustion chamber are to be determined.

Assumptions 1 The equilibrium composition consists of CO₂, CO, and O₂. **2** The constituents of the mixture are ideal gases.

Analysis (a) We first need to calculate the amount of oxygen used per lbmol of CO before we can write the combustion equation,

$$\nu_{\text{CO}} = \frac{RT}{P} = \frac{(0.3831 \text{ psia} \cdot \text{ft}^3 / \text{lbm} \cdot \text{R})(560 \text{ R})}{16 \text{ psia}} = 13.41 \text{ ft}^3 / \text{lbm}$$

$$\dot{m}_{\text{CO}} = \frac{\dot{V}_{\text{CO}}}{\nu_{\text{CO}}} = \frac{12.5 \text{ ft}^3 / \text{min}}{13.41 \text{ ft}^3 / \text{lbm}} = 0.932 \text{ lbm} / \text{min}$$

Then the molar air-fuel ratio becomes (it is actually O₂-fuel ratio)

$$\overline{\text{AF}} = \frac{N_{\text{O}_2}}{N_{\text{fuel}}} = \frac{\dot{m}_{\text{O}_2} / M_{\text{O}_2}}{\dot{m}_{\text{fuel}} / M_{\text{fuel}}} = \frac{(0.7 \text{ lbm} / \text{min}) / (32 \text{ lbm} / \text{lbmol})}{(0.932 \text{ lbm} / \text{min}) / (28 \text{ lbm} / \text{lbmol})} = 0.657 \text{ lbmol O}_2 / \text{lbmol fuel}$$

Then the combustion equation can be written as

The equilibrium equation among CO₂, CO, and O₂ can be expressed as

and

$$K_p = \frac{N_{\text{CO}}^{\nu_{\text{CO}}} N_{\text{O}_2}^{\nu_{\text{O}_2}}}{N_{\text{CO}_2}^{\nu_{\text{CO}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{CO}} + \nu_{\text{O}_2} - \nu_{\text{CO}_2})}$$

where

$$N_{\text{total}} = x + (1-x) + (0.657 - 0.5x) = 1.657 - 0.5x$$

$$P = 16 / 14.7 = 1.088 \text{ atm}$$

From Table A-28, $\ln K_p = -6.635$ at $T = 3600 \text{ R} = 2000 \text{ K}$. Thus $K_p = 1.314 \times 10^{-3}$. Substituting,

$$1.314 \times 10^{-3} = \frac{(1-x)(0.657 - 0.5x)^{0.5}}{x} \left(\frac{1.088}{1.657 - 0.5x} \right)^{1.5-1}$$

Solving for x ,

$$x = 0.9966$$

Then the combustion equation and the equilibrium composition can be expressed as

and

(b) The heat transfer for this combustion process is determined from the steady-flow energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ on the combustion chamber with $W = 0$,

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° Btu/lbmol	$\bar{h}_{537\text{R}}$ Btu/lbmol	$\bar{h}_{560\text{R}}$ Btu/lbmol	$\bar{h}_{3600\text{R}}$ Btu/lbmol
CO	-47,540	3725.1	3889.5	28,127
O ₂	0	3725.1	---	29,174
CO ₂	-169,300	4027.5	---	43,411

Substituting,

$$\begin{aligned}
 -\dot{Q}_{\text{out}} &= 0.9966(-169,300 + 43,411 - 4027.5) \\
 &\quad + 0.0034(-47,540 + 28,127 - 3725.1) \\
 &\quad + 0.1587(0 + 29,174 - 3725.1) \\
 &\quad - 1(-47,540 + 3889.5 - 3725.1) - 0 \\
 &= -78,139 \text{ Btu / lbmol of CO}
 \end{aligned}$$

or $\dot{Q}_{\text{out}} = 78,139 \text{ Btu / lbm of CO}$

The mass flow rate of CO can be expressed in terms of the mole numbers as

$$\dot{N} = \frac{\dot{m}}{M} = \frac{0.932 \text{ lbm / min}}{28 \text{ lbm / lbmol}} = 0.0333 \text{ lbmol / min}$$

Thus the rate of heat transfer is

$$\dot{Q}_{\text{out}} = \dot{N} \times Q_{\text{out}} = (0.0333 \text{ lbmol / min})(78,139 \text{ Btu / lbmol}) = \mathbf{2602 \text{ Btu / min}}$$

16-35 Liquid propane enters a combustion chamber. The equilibrium composition of product gases and the rate of heat transfer from the combustion chamber are to be determined.

Assumptions 1 The equilibrium composition consists of CO_2 , H_2O , CO , N_2 , and O_2 . **2** The constituents of the mixture are ideal gases.

Analysis (a) Considering 1 kmol of C_3H_8 , the stoichiometric combustion equation can be written as

where a_{th} is the stoichiometric coefficient and is determined from the O_2 balance,

$$2.5a_{\text{th}} = 3 + 2 + 1.5a_{\text{th}} \longrightarrow a_{\text{th}} = 5$$

Then the actual combustion equation with 150% excess air and some CO in the products can be written as

After combustion, there will be no C_3H_8 present in the combustion chamber, and H_2O will act like an inert gas. The equilibrium equation among CO_2 , CO , and O_2 can be expressed as

and

$$K_p = \frac{N_{\text{CO}}^{\nu_{\text{CO}}} N_{\text{O}_2}^{\nu_{\text{O}_2}}}{N_{\text{CO}_2}^{\nu_{\text{CO}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{CO}} + \nu_{\text{O}_2} - \nu_{\text{CO}_2})}$$

where

$$N_{\text{total}} = x + (3-x) + (9-0.5x) + 4 + 47 = 63 - 0.5x$$

From Table A-28, $\ln K_p = -17.871$ at 1200 K. Thus $K_p = 1.73 \times 10^{-8}$. Substituting,

$$1.73 \times 10^{-8} = \frac{(3-x)(9-0.5x)^{0.5}}{x} \left(\frac{2}{63-0.5x} \right)^{1.5-1}$$

Solving for x ,

$$x = 2.9999999 \cong 3.0$$

Therefore, the amount CO in the product gases is negligible, and it can be disregarded with no loss in accuracy. Then the combustion equation and the equilibrium composition can be expressed as

and

(b) The heat transfer for this combustion process is determined from the steady-flow energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ on the combustion chamber with $W = 0$,

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. From the tables, (The \bar{h}_f° of liquid propane is obtained by adding the h_{fg} at 25°C to \bar{h}_f° of gaseous propane).

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{285\text{ K}}$ kJ/kmol	$\bar{h}_{298\text{ K}}$ kJ/kmol	$\bar{h}_{1200\text{ K}}$ kJ/kmol
$\text{C}_3\text{H}_8 (\ell)$	-118,910	---	---	---
O_2	0	8696.5	8682	38,447
N_2	0	8286.5	8669	36,777
$\text{H}_2\text{O} (g)$	-241,820	---	9904	44,380
CO_2	-393,520	---	9364	53,848

Substituting,

$$\begin{aligned}
 -Q_{\text{out}} &= 3(-393,520 + 53,848 - 9364) + 4(-241,820 + 44,380 - 9904) \\
 &\quad + 7.5(0 + 38,447 - 8682) + 47(0 + 36,777 - 8669) \\
 &\quad - 1(-118,910 + h_{298} - h_{298}) - 12.5(0 + 8296.5 - 8682) \\
 &\quad - 47(0 + 8186.5 - 8669) \\
 &= -185,764 \text{ kJ / kmol of } \text{C}_3\text{H}_8
 \end{aligned}$$

or

$$Q_{\text{out}} = 185,764 \text{ kJ / kmol of } \text{C}_3\text{H}_8$$

The mass flow rate of C_3H_8 can be expressed in terms of the mole numbers as

$$\dot{N} = \frac{\dot{m}}{M} = \frac{1.2 \text{ kg / min}}{44 \text{ kg / kmol}} = 0.02727 \text{ kmol / min}$$

Thus the rate of heat transfer is

$$\dot{Q}_{\text{out}} = \dot{N} \times Q_{\text{out}} = (0.02727 \text{ kmol/min})(185,746 \text{ kJ/kmol}) = \mathbf{5066 \text{ kJ/min}}$$

The equilibrium constant for the reaction $\frac{1}{2} \text{N}_2 + \frac{1}{2} \text{O}_2 \leftrightarrow \text{NO}$ is $\ln K_p = -7.569$, which is very small. This indicates that the amount of NO formed during this process will be very small, and can be disregarded.

16-36 Problem 16-35 is reconsidered. It is to be investigated if it is realistic to disregard the presence of NO in the product gases.

Analysis The problem is solved using EES, and the solution is given below.

"To solve this problem, the Gibbs function of the product gases is minimized. Click on the Min/Max icon."

For this problem at 1200 K the moles of CO are 0.000 and moles of NO are 0.000, thus we can disregard both the CO and NO. However, try some product temperatures above 1286 K and observe the sign change on the Q_out and the amount of CO and NO present as the product temperature increases."

"The reaction of C₃H₈(liq) with excess air can be written:

The coefficients A_{th} and EX are the theoretical oxygen and the percent excess air on a decimal basis. Coefficients a, b, c, d, e, and f are found by minimizing the Gibbs Free Energy at a total pressure of the product gases P_{Prod} and the product temperature T_{Prod}.

The equilibrium solution can be found by applying the Law of Mass Action or by minimizing the Gibbs function. In this problem, the Gibbs function is directly minimized using the optimization capabilities built into EES.

To run this program, click on the Min/Max icon. There are six compounds present in the products subject to four specie balances, so there are two degrees of freedom. Minimize the Gibbs function of the product gases with respect to two molar quantities such as coefficients b and f. The equilibrium mole numbers a, b, c, d, e, and f will be determined and displayed in the Solution window."

```

16-37 Oxygen is heated during a steady-flow process. The rate of heat supply needed during this process is to be determined for two cases.

Assumptions 1 The equilibrium composition consists of O_2 and O . **2** All components behave as ideal gases.

Analysis (a) Assuming some O_2 dissociates into O , the dissociation equation can be written as

The equilibrium equation among O_2 and O can be expressed as

Assuming ideal gas behavior for all components, the equilibrium constant relation can be expressed as

$$K_p = \frac{N_O^{\nu_O}}{N_{O_2}^{\nu_{O_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{\nu_O - \nu_{O_2}}$$

where $N_{\text{total}} = x + 2(1-x) = 2-x$

From Table A-28, $\ln K_p = -4.357$ at 3000 K. Thus $K_p = 0.01282$. Substituting,

$$0.01282 = \frac{(2-2x)^2}{x} \left(\frac{1}{2-x} \right)^{2-1}$$

Solving for x gives

$$x = 0.943$$

Then the dissociation equation becomes

The heat transfer for this combustion process is determined from the steady-flow energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ on the combustion chamber with $W = 0$,

$$Q_{\text{in}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the O_2 and O to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{ K}}$ kJ/kmol	$\bar{h}_{3000\text{ K}}$ kJ/kmol
O	249,190	6852	63,425
O_2	0	8682	106,780

Substituting,

$$Q_{\text{in}} = 0.943(0 + 106,780 - 8682) + 0.114(249,190 + 63,425 - 6852) - 0 = 127,363 \text{ kJ / kmol } O_2$$

The mass flow rate of O_2 can be expressed in terms of the mole numbers as

$$\dot{N} = \frac{\dot{m}}{M} = \frac{0.5 \text{ kg/min}}{32 \text{ kg/kmol}} = 0.01563 \text{ kmol/min}$$

Thus the rate of heat transfer is

$$\dot{Q}_{\text{in}} = \dot{N} \times Q_{\text{in}} = (0.01563 \text{ kmol/min})(127,363 \text{ kJ/kmol}) = \mathbf{1990 \text{ kJ/min}}$$

(b) If no O_2 dissociates into O , then the process involves no chemical reactions and the heat transfer can be determined from the steady-flow energy balance for nonreacting systems to be

$$\dot{Q}_{\text{in}} = \dot{m}(h_2 - h_1) = \dot{N}(\bar{h}_2 - \bar{h}_1) = (0.01563 \text{ kmol/min})(106,780 - 8682) \text{ kJ/kmol} = \mathbf{1533 \text{ kJ/min}}$$

16-38 The equilibrium constant, K_p is to be estimated at 2500 K for the reaction $\text{CO} + \text{H}_2\text{O} = \text{CO}_2 + \text{H}_2$.

Analysis (a) The K_p value of a reaction at a specified temperature can be determined from the Gibbs function data using

$$K_p = e^{-\Delta G^*(T)/R_u T} \quad \text{or} \quad \ln K_p = -\Delta G^*(T)/R_u T$$

where

$$\Delta G^*(T) = \nu_{\text{CO}_2} \bar{g}_{\text{CO}_2}^*(T) + \nu_{\text{H}_2} \bar{g}_{\text{H}_2}^*(T) - \nu_{\text{CO}} \bar{g}_{\text{CO}}^*(T) - \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T)$$

At 2500 K,

$$\begin{aligned} \Delta G^*(T) &= \nu_{\text{CO}_2} \bar{g}_{\text{CO}_2}^*(T) + \nu_{\text{H}_2} \bar{g}_{\text{H}_2}^*(T) - \nu_{\text{CO}} \bar{g}_{\text{CO}}^*(T) - \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T) \\ &= \nu_{\text{CO}_2} (\bar{h} - T\bar{s})_{\text{CO}_2} + \nu_{\text{H}_2} (\bar{h} - T\bar{s})_{\text{H}_2} - \nu_{\text{CO}} (\bar{h} - T\bar{s})_{\text{CO}} - \nu_{\text{H}_2\text{O}} (\bar{h} - T\bar{s})_{\text{H}_2\text{O}} \\ &= 1[-393,520 + 131,290 - 9364] - (2500)(322.808) \\ &\quad + 1[(0 + 78,960 - 8468) - (2500)(196.125)] \\ &\quad - 1[-110,530 + 83,692 - 8669] - (2500)(266.755) \\ &\quad - 1[-241,820 + 108,868 - 9904] - (2500)(276.286) \\ &= 37,531 \text{ kJ/kmol} \end{aligned}$$

Substituting,

$$\ln K_p = -\frac{37,531 \text{ kJ/kmol}}{(8.314 \text{ kJ/kmol} \cdot \text{K})(2500 \text{ K})} = -1.8057 \longrightarrow K_p = \mathbf{0.1644}$$

The equilibrium constant may be estimated using the integrated van't Hoff equation:

$$\begin{aligned} \ln \left(\frac{K_{p,\text{est}}}{K_{p1}} \right) &= \frac{\bar{h}_R}{R_u} \left(\frac{1}{T_R} - \frac{1}{T} \right) \\ \ln \left(\frac{K_{p,\text{est}}}{0.2209} \right) &= \frac{-26,176 \text{ kJ/kmol}}{8.314 \text{ kJ/kmol} \cdot \text{K}} \left(\frac{1}{2000 \text{ K}} - \frac{1}{2500 \text{ K}} \right) \longrightarrow K_{p,\text{est}} = \mathbf{0.1612} \end{aligned}$$

16-39 A constant volume tank contains a mixture of H_2 and O_2 . The contents are ignited. The final temperature and pressure in the tank are to be determined.

Analysis The reaction equation with products in equilibrium is

The coefficients are determined from the mass balances

$$\text{Hydrogen balance:} \quad 2 = 2a + 2b$$

$$\text{Oxygen balance:} \quad 2 = b + 2c$$

The assumed equilibrium reaction is

The K_p value of a reaction at a specified temperature can be determined from the Gibbs function data using

$$K_p = e^{-\Delta G^*(T)/R_u T} \quad \text{or} \quad \ln K_p = -\Delta G^*(T) / R_u T$$

where

$$\Delta G^*(T) = \nu_{\text{H}_2} \bar{g}_{\text{H}_2}^*(T_{\text{prod}}) + \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T_{\text{prod}}) - \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T_{\text{prod}})$$

and the Gibbs functions are given by

$$\bar{g}_{\text{H}_2}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}} \bar{s})_{\text{H}_2}$$

$$\bar{g}_{\text{O}_2}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}} \bar{s})_{\text{O}_2}$$

$$\bar{g}_{\text{H}_2\text{O}}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}} \bar{s})_{\text{H}_2\text{O}}$$

The equilibrium constant is also given by

$$K_p = \frac{a^1 c^{0.5}}{b^1} \left(\frac{P}{N_{\text{tot}}} \right)^{1+0.5-1} = \frac{ac^{0.5}}{b} \left(\frac{P_2 / 101.3}{a+b+c} \right)^{0.5}$$

An energy balance on the tank under adiabatic conditions gives

$$U_R = U_P$$

where

$$\begin{aligned} U_R &= 1(\bar{h}_{\text{H}_2@25^\circ\text{C}} - R_u T_{\text{reac}}) + 1(\bar{h}_{\text{O}_2@25^\circ\text{C}} - R_u T_{\text{reac}}) \\ &= 0 - (8.314 \text{ kJ/kmol}\cdot\text{K})(298.15 \text{ K}) + 0 - (8.314 \text{ kJ/kmol}\cdot\text{K})(298.15 \text{ K}) = -4958 \text{ kJ/kmol} \end{aligned}$$

$$U_P = a(\bar{h}_{\text{H}_2@T_{\text{prod}}} - R_u T_{\text{prod}}) + b(\bar{h}_{\text{H}_2\text{O}@T_{\text{prod}}} - R_u T_{\text{prod}}) + c(\bar{h}_{\text{O}_2@T_{\text{prod}}} - R_u T_{\text{prod}})$$

The relation for the final pressure is

$$P_2 = \frac{N_{\text{tot}}}{N_1} \frac{T_{\text{prod}}}{T_{\text{reac}}} P_1 = \left(\frac{a+b+c}{2} \right) \left(\frac{T_{\text{prod}}}{298.15 \text{ K}} \right) (101.3 \text{ kPa})$$

Solving all the equations simultaneously using EES, we obtain the final temperature and pressure in the tank to be

$$T_{\text{prod}} = \mathbf{3857\text{K}}$$

$$P_2 = \mathbf{1043\text{kPa}}$$

16-40 It is to be shown that as long as the extent of the reaction, α , for the disassociation reaction $X_2 \Leftrightarrow 2X$ is smaller than one, α is given by $\alpha = \sqrt{\frac{K_p}{4 + K_p}}$

Assumptions The reaction occurs at the reference temperature.

Analysis The stoichiometric and actual reactions can be written as

Stoichiometric: $X_2 \Leftrightarrow 2X$ (thus $\nu_{X_2} = 1$ and $\nu_X = 2$)

Actual: $X_2 \Leftrightarrow \underbrace{(1-\alpha)X_2}_{\text{react.}} + \underbrace{2\alpha X}_{\text{prod.}}$

The equilibrium constant K_p is given by

$$K_p = \frac{N_X^{\nu_X}}{N_{X_2}^{\nu_{X_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{\nu_X - \nu_{X_2}} = \frac{(2\alpha)^2}{(1-\alpha)} \left(\frac{1}{\alpha+1} \right)^{2-1} = \frac{4\alpha^2}{(1-\alpha)(1+\alpha)}$$

Solving this expression for α gives

$$\alpha = \sqrt{\frac{K_p}{4 + K_p}}$$

Simultaneous Reactions

16-41C It can be expressed as “ $(dG)_{T,P} = 0$ for each reaction.” Or as “the K_p relation for each reaction must be satisfied.”

16-42C The number of K_p relations needed to determine the equilibrium composition of a reacting mixture is equal to the difference between the number of species present in the equilibrium mixture and the number of elements.

16-43 Two chemical reactions are occurring in a mixture. The equilibrium composition at a specified temperature is to be determined.

Assumptions 1 The equilibrium composition consists of H_2O , OH , O_2 , and H_2 .

2 The constituents of the mixture are ideal gases.

Analysis The reaction equation during this process can be expressed as

Mass balances for hydrogen and oxygen yield

$$\text{H balance:} \quad 2 = 2x + 2y + w \quad (1)$$

$$\text{O balance:} \quad 1 = x + 2z + w \quad (2)$$

The mass balances provide us with only two equations with four unknowns, and thus we need to have two more equations (to be obtained from the K_p relations) to determine the equilibrium composition of the mixture. They are

The equilibrium constant for these two reactions at 3400 K are determined from Table A-28 to be

$$\ln K_{p1} = -1.891 \longrightarrow K_{p1} = 0.15092$$

$$\ln K_{p2} = -1.576 \longrightarrow K_{p2} = 0.20680$$

The K_p relations for these two simultaneous reactions are

$$K_{p1} = \frac{N_{\text{H}_2}^{v_{\text{H}_2}} N_{\text{O}_2}^{v_{\text{O}_2}}}{N_{\text{H}_2\text{O}}^{v_{\text{H}_2\text{O}}}} \left(\frac{P}{N_{\text{total}}} \right)^{(v_{\text{H}_2} + v_{\text{O}_2} - v_{\text{H}_2\text{O}})} \quad \text{and} \quad K_{p2} = \frac{N_{\text{H}_2}^{v_{\text{H}_2}} N_{\text{OH}}^{v_{\text{OH}}}}{N_{\text{H}_2\text{O}}^{v_{\text{H}_2\text{O}}}} \left(\frac{P}{N_{\text{total}}} \right)^{(v_{\text{H}_2} + v_{\text{OH}} - v_{\text{H}_2\text{O}})}$$

$$\text{where} \quad N_{\text{total}} = N_{\text{H}_2\text{O}} + N_{\text{H}_2} + N_{\text{O}_2} + N_{\text{OH}} = x + y + z + w$$

Substituting,

$$0.15092 = \frac{(y)(z)^{1/2}}{x} \left(\frac{1}{x + y + z + w} \right)^{1/2} \quad (3)$$

$$0.20680 = \frac{(w)(y)^{1/2}}{x} \left(\frac{1}{x + y + z + w} \right)^{1/2} \quad (4)$$

Solving Eqs. (1), (2), (3), and (4) simultaneously for the four unknowns x , y , z , and w yields

$$x = 0.574 \quad y = 0.308 \quad z = 0.095 \quad w = 0.236$$

Therefore, the equilibrium composition becomes

16-44 Two chemical reactions are occurring in a mixture. The equilibrium composition at a specified temperature is to be determined.

Assumptions 1 The equilibrium composition consists of CO_2 , CO , O_2 , and O . **2** The constituents of the mixture are ideal gases.

Analysis The reaction equation during this process can be expressed as

Mass balances for carbon and oxygen yield

$$\text{C balance:} \quad 2 = x + y \quad (1)$$

$$\text{O balance:} \quad 6 = 2x + y + 2z + w \quad (2)$$

$\text{CO}_2, \text{CO}, \text{O}_2, \text{O}$
3200 K
2 atm

The mass balances provide us with only two equations with four unknowns, and thus we need to have two more equations (to be obtained from the K_P relations) to determine the equilibrium composition of the mixture. They are

The equilibrium constant for these two reactions at 3200 K are determined from Table A-28 to be

$$\ln K_{P1} = -0.429 \longrightarrow K_{P1} = 0.6512$$

$$\ln K_{P2} = -3.072 \longrightarrow K_{P2} = 0.04633$$

The K_P relations for these two simultaneous reactions are

$$K_{P1} = \frac{N_{\text{CO}}^{v_{\text{CO}}} N_{\text{O}_2}^{v_{\text{O}_2}}}{N_{\text{CO}_2}^{v_{\text{CO}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(v_{\text{CO}} + v_{\text{O}_2} - v_{\text{CO}_2})}$$

$$K_{P2} = \frac{N_{\text{O}}^{v_{\text{O}}}}{N_{\text{O}_2}^{v_{\text{O}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{v_{\text{O}} - v_{\text{O}_2}}$$

where

$$N_{\text{total}} = N_{\text{CO}_2} + N_{\text{O}_2} + N_{\text{CO}} + N_{\text{O}} = x + y + z + w$$

Substituting,

$$0.6512 = \frac{(y)(z)^{1/2}}{x} \left(\frac{2}{x + y + z + w} \right)^{1/2} \quad (3)$$

$$0.04633 = \frac{w^2}{z} \left(\frac{2}{x + y + z + w} \right)^{2-1} \quad (4)$$

Solving Eqs. (1), (2), (3), and (4) simultaneously using an equation solver such as EES for the four unknowns x , y , z , and w yields

$$x = 1.127 \quad y = 0.8727 \quad z = 1.273 \quad w = 0.3258$$

Thus the equilibrium composition is

16-45 Two chemical reactions are occurring at high-temperature air. The equilibrium composition at a specified temperature is to be determined.

Assumptions 1 The equilibrium composition consists of O_2 , N_2 , O , and NO . **2** The constituents of the mixture are ideal gases.

Analysis The reaction equation during this process can be expressed as

Mass balances for nitrogen and oxygen yield

$$\text{N balance:} \quad 7.52 = 2x + y \quad (1)$$

$$\text{O balance:} \quad 2 = y + 2z + w \quad (2)$$

The mass balances provide us with only two equations with four unknowns, and thus we need to have two more equations (to be obtained from the K_p relations) to determine the equilibrium composition of the mixture. They are

The equilibrium constant for these two reactions at 3000 K are determined from Table A-28 to be

$$\ln K_{p1} = -2.114 \longrightarrow K_{p1} = 0.12075$$

$$\ln K_{p2} = -4.357 \longrightarrow K_{p2} = 0.01282$$

The K_p relations for these two simultaneous reactions are

$$K_{p1} = \frac{N_{NO}^{v_{NO}}}{N_{N_2}^{v_{N_2}} N_{O_2}^{v_{O_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(v_{NO} - v_{N_2} - v_{O_2})}$$

$$K_{p2} = \frac{N_O^{v_O}}{N_{O_2}^{v_{O_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{v_O - v_{O_2}}$$

$$\text{where } N_{\text{total}} = N_{N_2} + N_{NO} + N_{O_2} + N_O = x + y + z + w$$

Substituting,

$$0.12075 = \frac{y}{x^{0.5} z^{0.5}} \left(\frac{2}{x + y + z + w} \right)^{1 - 0.5 - 0.5} \quad (3)$$

$$0.01282 = \frac{w^2}{z} \left(\frac{2}{x + y + z + w} \right)^{2 - 1} \quad (4)$$

Solving Eqs. (1), (2), (3), and (4) simultaneously using EES for the four unknowns x , y , z , and w yields

$$x = 3.656 \quad y = 0.2086 \quad z = 0.8162 \quad w = 0.1591$$

Thus the equilibrium composition is

The equilibrium constant of the reaction $N_2 \Leftrightarrow 2N$ at 3000 K is $\ln K_p = -22.359$, which is much smaller than the K_p values of the reactions considered. Therefore, it is reasonable to assume that no N will be present in the equilibrium mixture.

16-46E Two chemical reactions are occurring in air. The equilibrium composition at a specified temperature is to be determined.

Assumptions **1** The equilibrium composition consists of O_2 , N_2 , O , and NO . **2** The constituents of the mixture are ideal gases.

Analysis The reaction equation during this process can be expressed as

Mass balances for nitrogen and oxygen yield

$$\text{N balance: } 7.52 = 2x + y \quad (1)$$

$$\text{O balance: } 2 = y + 2z + w \quad (2)$$

The mass balances provide us with only two equations with four unknowns, and thus we need to have two more equations (to be obtained from the K_p relations) to determine the equilibrium composition of the mixture. They are

The equilibrium constant for these two reactions at $T = 5400 \text{ R} = 3000 \text{ K}$ are determined from Table A-28 to be

$$\ln K_{P1} = -2.114 \longrightarrow K_{P1} = 0.12075$$

$$\ln K_{P2} = -4.357 \longrightarrow K_{P2} = 0.01282$$

The K_p relations for these two simultaneous reactions are

$$K_{P1} = \frac{N_{NO}^{v_{NO}}}{N_{N_2}^{v_{N_2}} N_{O_2}^{v_{O_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(v_{NO} - v_{N_2} - v_{O_2})}$$

$$K_{P2} = \frac{N_O^{v_O}}{N_{O_2}^{v_{O_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{v_O - v_{O_2}}$$

$$\text{where } N_{\text{total}} = N_{N_2} + N_{NO} + N_{O_2} + N_O = x + y + z + w$$

Substituting,

$$0.12075 = \frac{y}{x^{0.5} z^{0.5}} \left(\frac{1}{x + y + z + w} \right)^{1 - 0.5 - 0.5} \quad (3)$$

$$0.01282 = \frac{w^2}{z} \left(\frac{1}{x + y + z + w} \right)^{2 - 1} \quad (4)$$

Solving Eqs. (1), (2), (3), and (4) simultaneously for the four unknowns x , y , z , and w yields

$$x = 3.658 \quad y = 0.2048 \quad z = 0.7868 \quad w = 0.2216$$

Thus the equilibrium composition is

The equilibrium constant of the reaction $N_2 \Leftrightarrow 2N$ at 5400 R is $\ln K_p = -22.359$, which is much smaller than the K_p values of the reactions considered. Therefore, it is reasonable to assume that no N will be present in the equilibrium mixture.

14-47E Problem 16-46E is reconsidered. Using EES (or other) software, the equilibrium solution is to be obtained by minimizing the Gibbs function by using the optimization capabilities built into EES. This solution technique is to be compared with that used in the previous problem.

Analysis The problem is solved using EES, and the solution is given below.

"This example illustrates how EES can be used to solve multi-reaction chemical equilibria problems by directly minimizing the Gibbs function.

Two of the four coefficients, a, b, c, and d, are found by minimizing the Gibbs function at a total pressure of 1 atm and a temperature of 5400 R. The other two are found from mass balances.

The equilibrium solution can be found by applying the Law of Mass Action to two simultaneous equilibrium reactions or by minimizing the Gibbs function. In this problem, the Gibbs function is directly minimized using the optimization capabilities built into EES.

To run this program, select MinMax from the Calculate menu. There are four compounds present in the products subject to two elemental balances, so there are two degrees of freedom. Minimize Gibbs with respect to two molar quantities such as coefficients b and d. The equilibrium mole numbers of each specie will be determined and displayed in the Solution window.

Minimizing the Gibbs function to find the equilibrium composition requires good initial guesses."

Discussion The equilibrium composition in the above table are based on the reaction in which the reactants are 0.21 kmol O_2 and 0.79 kmol N_2 . If you multiply the equilibrium composition mole numbers above with 4.76, you will obtain equilibrium composition for the reaction in which the reactants are 1 kmol O_2 and 3.76 kmol N_2 . This is the case in problem 16-46E.

16-48 Water vapor is heated during a steady-flow process. The rate of heat supply for a specified exit temperature is to be determined for two cases.

Assumptions 1 The equilibrium composition consists of H_2O , OH , O_2 , and H_2 . **2** The constituents of the mixture are ideal gases.

Analysis (a) Assuming some H_2O dissociates into H_2 , O_2 , and O , the dissociation equation can be written as

Mass balances for hydrogen and oxygen yield

$$\text{H balance:} \quad 2 = 2x + 2y + w \quad (1)$$

$$\text{O balance:} \quad 1 = x + 2z + w \quad (2)$$

The mass balances provide us with only two equations with four unknowns, and thus we need to have two more equations (to be obtained from the K_p relations) to determine the equilibrium composition of the mixture. They are

The equilibrium constant for these two reactions at 3000 K are determined from Table A-28 to be

$$\ln K_{p1} = -3.086 \longrightarrow K_{p1} = 0.04568$$

$$\ln K_{p2} = -2.937 \longrightarrow K_{p2} = 0.05302$$

The K_p relations for these three simultaneous reactions are

$$K_{p1} = \frac{N_{\text{H}_2}^{\nu_{\text{H}_2}} N_{\text{O}_2}^{\nu_{\text{O}_2}}}{N_{\text{H}_2\text{O}}^{\nu_{\text{H}_2\text{O}}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{H}_2} + \nu_{\text{O}_2} - \nu_{\text{H}_2\text{O}})}$$

$$K_{p2} = \frac{N_{\text{H}_2}^{\nu_{\text{H}_2}} N_{\text{OH}}^{\nu_{\text{OH}}}}{N_{\text{H}_2\text{O}}^{\nu_{\text{H}_2\text{O}}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{H}_2} + \nu_{\text{OH}} - \nu_{\text{H}_2\text{O}})}$$

where

$$N_{\text{total}} = N_{\text{H}_2\text{O}} + N_{\text{H}_2} + N_{\text{O}_2} + N_{\text{OH}} = x + y + z + w$$

Substituting,

$$0.04568 = \frac{(y)(z)^{1/2}}{x} \left(\frac{1}{x + y + z + w} \right)^{1/2} \quad (3)$$

$$0.05302 = \frac{(w)(y)^{1/2}}{x} \left(\frac{1}{x + y + z + w} \right)^{1/2} \quad (4)$$

Solving Eqs. (1), (2), (3), and (4) simultaneously for the four unknowns x , y , z , and w yields

$$x = 0.7835 \quad y = 0.1622 \quad z = 0.05396 \quad w = 0.1086$$

Thus the balanced equation for the dissociation reaction is

The heat transfer for this dissociation process is determined from the steady-flow energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ with $W = 0$,

$$Q_{\text{in}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the O_2 and O to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{ K}}$ kJ/kmol	$\bar{h}_{3000\text{ K}}$ kJ/kmol
H_2O	-241,820	9904	136,264
H_2	0	8468	97,211
O_2	0	8682	106,780
OH	39,460	9188	98,763

Substituting,

$$\begin{aligned}
 Q_{in} &= 0.7835(-241,820 + 136,264 - 9904) \\
 &\quad + 0.1622(0 + 97,211 - 8468) \\
 &\quad + 0.05396(0 + 106,780 - 8682) \\
 &\quad + 0.1086(39,460 + 98,763 - 9188) - (-241,820) \\
 &= 185,058 \text{ kJ/kmol } H_2O
 \end{aligned}$$

The mass flow rate of H_2O can be expressed in terms of the mole numbers as

$$\dot{N} = \frac{\dot{m}}{M} = \frac{0.2 \text{ kg/min}}{18 \text{ kg/kmol}} = 0.01111 \text{ kmol/min}$$

Thus,

$$\dot{Q}_{in} = \dot{N} \times Q_{in} = (0.01111 \text{ kmol/min})(185,058 \text{ kJ/kmol}) = \mathbf{2056 \text{ kJ/min}}$$

(b) If no dissociates takes place, then the process involves no chemical reactions and the heat transfer can be determined from the steady-flow energy balance for nonreacting systems to be

$$\begin{aligned}
 \dot{Q}_{in} &= \dot{m}(h_2 - h_1) = \dot{N}(\bar{h}_2 - \bar{h}_1) \\
 &= (0.01111 \text{ kmol/min})(136,264 - 9904) \text{ kJ/kmol} \\
 &= \mathbf{1404 \text{ kJ/min}}
 \end{aligned}$$

16-49 Problem 16-48 is reconsidered. The effect of the final temperature on the rate of heat supplied for the two cases is to be studied.

Analysis The problem is solved using EES, and the solution is given below.

"Given"

$$T1=298 \text{ [K]}$$

$$T2=3000 \text{ [K]}$$

$$P=1 \text{ [atm]}$$

$$\dot{m}=0.2 \text{ [kg/min]}$$

$$T0=298 \text{ [K]}$$

16-50  Ethyl alcohol C_2H_5OH (gas) is burned in a steady-flow adiabatic combustion chamber with 40 percent excess air. The adiabatic flame temperature of the products is to be determined and the adiabatic flame temperature as a function of the percent excess air is to be plotted.

Analysis The complete combustion reaction in this case can be written as

where a_{th} is the stoichiometric coefficient for air. The oxygen balance gives

$$1 + (1 + Ex)a_{th} \times 2 = 2 \times 2 + 3 \times 1 + (Ex)(a_{th}) \times 2$$

The reaction equation with products in equilibrium is

The coefficients are determined from the mass balances

Carbon balance: $2 = a + b$

Hydrogen balance: $6 = 2d \longrightarrow d = 3$

Oxygen balance: $1 + (1 + Ex)a_{th} \times 2 = a \times 2 + b + d + e \times 2 + g$

Nitrogen balance: $(1 + Ex)a_{th} \times 3.76 \times 2 = f \times 2 + g$

Solving the above equations, we find the coefficients to be

$$Ex = 0.4, a_{th} = 3, a = 1.995, b = 0.004712, d = 3, e = 1.17, f = 15.76, g = 0.06428$$

Then, we write the balanced reaction equation as

Total moles of products at equilibrium are

$$N_{tot} = 1.995 + 0.004712 + 3 + 1.17 + 15.76 = 21.99$$

The first assumed equilibrium reaction is

The K_p value of a reaction at a specified temperature can be determined from the Gibbs function data using

$$K_{p1} = \exp\left(\frac{-\Delta G_1^*(T_{prod})}{R_u T_{prod}}\right)$$

Where $\Delta G_1^*(T_{prod}) = \nu_{CO} \bar{g}_{CO}^*(T_{prod}) + \nu_{O_2} \bar{g}_{O_2}^*(T_{prod}) - \nu_{CO_2} \bar{g}_{CO_2}^*(T_{prod})$

and the Gibbs functions are defined as

$$\bar{g}_{CO}^*(T_{prod}) = (\bar{h} - T_{prod} \bar{s})_{CO}$$

$$\bar{g}_{O_2}^*(T_{prod}) = (\bar{h} - T_{prod} \bar{s})_{O_2}$$

$$\bar{g}_{CO_2}^*(T_{prod}) = (\bar{h} - T_{prod} \bar{s})_{CO_2}$$

The equilibrium constant is also given by

$$K_{p1} = \frac{b e^{0.5}}{a} \left(\frac{P}{N_{tot}}\right)^{1+0.5-1} = \frac{(0.004712)(1.17)^{0.5}}{1.995} \left(\frac{1}{21.99}\right)^{0.5} = 0.0005447$$

The second assumed equilibrium reaction is

Also, for this reaction, we have

$$\bar{g}_{\text{NO}}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}}\bar{s})_{\text{NO}}$$

$$\bar{g}_{\text{N}_2}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}}\bar{s})_{\text{N}_2}$$

$$\bar{g}_{\text{O}_2}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}}\bar{s})_{\text{O}_2}$$

$$\Delta G_2^*(T_{\text{prod}}) = \nu_{\text{NO}}\bar{g}_{\text{NO}}^*(T_{\text{prod}}) - \nu_{\text{N}_2}\bar{g}_{\text{N}_2}^*(T_{\text{prod}}) - \nu_{\text{O}_2}\bar{g}_{\text{O}_2}^*(T_{\text{prod}})$$

$$K_{p2} = \exp\left(\frac{-\Delta G_2^*(T_{\text{prod}})}{R_u T_{\text{prod}}}\right)$$

$$K_{p2} = \left(\frac{P}{N_{\text{tot}}}\right)^{1-0.5-0.5} \frac{g}{e^{0.5} f^{0.5}} = \left(\frac{1}{21.99}\right)^0 \frac{0.06428}{(1.17)^{0.5} (15.76)^{0.5}} = 0.01497$$

A steady flow energy balance gives

$$H_R = H_P$$

where

$$\begin{aligned} H_R &= \bar{h}_{f,\text{fuel}@25^\circ\text{C}}^\circ + 4.2\bar{h}_{\text{O}_2@25^\circ\text{C}} + 15.79\bar{h}_{\text{N}_2@25^\circ\text{C}} \\ &= (-235,310 \text{ kJ/kmol}) + 4.2(0) + 15.79(0) = -235,310 \text{ kJ/kmol} \end{aligned}$$

$$H_P = 1.995\bar{h}_{\text{CO}_2@T_{\text{prod}}} + 0.004712\bar{h}_{\text{CO}@T_{\text{prod}}} + 3h_{\text{H}_2\text{O}@T_{\text{prod}}} + 1.17\bar{h}_{\text{O}_2@T_{\text{prod}}} + 15.76\bar{h}_{\text{N}_2@T_{\text{prod}}} + 0.06428\bar{h}_{\text{NO}@T_{\text{prod}}}$$

Solving the energy balance equation using EES, we obtain the adiabatic flame temperature

$$T_{\text{prod}} = \mathbf{1901 \text{ K}}$$

Variations of K_p with Temperature

16-51C It enables us to determine the enthalpy of reaction \bar{h}_R from a knowledge of equilibrium constant K_p .

16-52C At 2000 K since combustion processes are exothermic, and exothermic reactions are more complete at lower temperatures.

16-53 The \bar{h}_R value for the dissociation process $O_2 \Leftrightarrow 2O$ at a specified temperature is to be determined using enthalpy and K_p data.

Assumptions Both the reactants and products are ideal gases.

Analysis (a) The dissociation equation of O_2 can be expressed as

The \bar{h}_R of the dissociation process of O_2 at 3100 K is the amount of energy absorbed or released as one kmol of O_2 dissociates in a steady-flow combustion chamber at a temperature of 3100 K, and can be determined from

$$\bar{h}_R = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the O_2 and O to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{ K}}$ kJ/kmol	$\bar{h}_{2900\text{ K}}$ kJ/kmol
O	249,190	6852	65,520
O_2	0	8682	110,784

Substituting,

$$\begin{aligned} \bar{h}_R &= 2(249,190 + 65,520 - 6852) - 1(0 + 110,784 - 8682) \\ &= \mathbf{513,614\text{ kJ/kmol}} \end{aligned}$$

(b) The \bar{h}_R value at 3100 K can be estimated by using K_p values at 3000 K and 3200 K (the closest two temperatures to 3100 K for which K_p data are available) from Table A-28,

$$\begin{aligned} \ln \frac{K_{P2}}{K_{P1}} &\cong \frac{\bar{h}_R}{R_u} \left(\frac{1}{T_1} - \frac{1}{T_2} \right) \quad \text{or} \quad \ln K_{P2} - \ln K_{P1} \cong \frac{\bar{h}_R}{R_u} \left(\frac{1}{T_1} - \frac{1}{T_2} \right) \\ -3.072 - (-4.357) &\cong \frac{\bar{h}_R}{8.314\text{ kJ/kmol}\cdot\text{K}} \left(\frac{1}{3000\text{ K}} - \frac{1}{3200\text{ K}} \right) \\ \bar{h}_R &\cong \mathbf{512,808\text{ kJ/kmol}} \end{aligned}$$

16-54 The \bar{h}_R at a specified temperature is to be determined using the enthalpy and K_P data.

Assumptions Both the reactants and products are ideal gases.

Analysis (a) The complete combustion equation of CO can be expressed as

The \bar{h}_R of the combustion process of CO at 1800 K is the amount of energy released as one kmol of CO is burned in a steady-flow combustion chamber at a temperature of 1800 K, and can be determined from

$$\bar{h}_R = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the CO, O₂ and CO₂ to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{ K}}$ kJ/kmol	$\bar{h}_{1800\text{ K}}$ kJ/kmol
CO ₂	-393,520	9364	88,806
CO	-110,530	8669	58,191
O ₂	0	8682	60,371

Substituting,

$$\begin{aligned} \bar{h}_R &= 1(-393,520 + 88,806 - 9904) \\ &\quad - 1(-110,530 + 58,191 - 8669) \\ &\quad - 0.5(0 + 60,371 - 8682) \\ &= -289,455 \text{ kJ/kmol} \end{aligned}$$

(b) The \bar{h}_R value at 1800 K can be estimated by using K_P values at 1600 K and 2000 K (the closest two temperatures to 1800 K for which K_P data are available) from Table A-28,

$$\begin{aligned} \ln \frac{K_{P2}}{K_{P1}} &\cong \frac{\bar{h}_R}{R_u} \left(\frac{1}{T_1} - \frac{1}{T_2} \right) \quad \text{or} \quad \ln K_{P2} - \ln K_{P1} \cong \frac{\bar{h}_R}{R_u} \left(\frac{1}{T_1} - \frac{1}{T_2} \right) \\ 6.635 - 10.830 &\cong \frac{\bar{h}_R}{8.314 \text{ kJ/kmol} \cdot \text{K}} \left(\frac{1}{1600 \text{ K}} - \frac{1}{2000 \text{ K}} \right) \\ \bar{h}_R &\cong -279,020 \text{ kJ/kmol} \end{aligned}$$

16-55E The \bar{h}_R at a specified temperature is to be determined using the enthalpy and K_P data.

Assumptions Both the reactants and products are ideal gases.

Analysis (a) The complete combustion equation of CO can be expressed as

The \bar{h}_R of the combustion process of CO at 3960 R is the amount of energy released as one kmol of H_2 is burned in a steady-flow combustion chamber at a temperature of 3960 R, and can be determined from

$$\bar{h}_R = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the CO, O_2 and CO_2 to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° Btu/lbmol	$\bar{h}_{537\text{ R}}$ Btu/lbmol	$\bar{h}_{3960\text{ R}}$ Btu/lbmol
CO_2	-169,300	4027.5	48,647
CO	-47,540	3725.1	31,256.5
O_2	0	3725.1	32,440.5

Substituting,

$$\begin{aligned} \bar{h}_R &= 1(-169,300 + 48,647 - 4027.5) \\ &\quad - 1(-47,540 + 31,256.5 - 3725.1) \\ &\quad - 0.5(0 + 32,440.5 - 3725.1) \\ &= \mathbf{-119,030 \text{ Btu/lbmol}} \end{aligned}$$

(b) The \bar{h}_R value at 3960 R can be estimated by using K_P values at 3600 R and 4320 R (the closest two temperatures to 3960 R for which K_P data are available) from Table A-28,

$$\begin{aligned} \ln \frac{K_{P2}}{K_{P1}} &\cong \frac{\bar{h}_R}{R_u} \left(\frac{1}{T_1} - \frac{1}{T_2} \right) \quad \text{or} \quad \ln K_{P2} - \ln K_{P1} \cong \frac{\bar{h}_R}{R_u} \left(\frac{1}{T_1} - \frac{1}{T_2} \right) \\ 3.860 - 6.635 &\cong \frac{\bar{h}_R}{1.986 \text{ Btu/lbmol} \cdot \text{R}} \left(\frac{1}{3600 \text{ R}} - \frac{1}{4320 \text{ R}} \right) \\ \bar{h}_R &\cong \mathbf{-119,041 \text{ Btu/lbmol}} \end{aligned}$$

16-56 The K_p value of the combustion process $\text{H}_2 + 1/2\text{O}_2 \rightleftharpoons \text{H}_2\text{O}$ is to be determined at a specified temperature using \bar{h}_R data and K_p value.

Assumptions Both the reactants and products are ideal gases.

Analysis The \bar{h}_R and K_p data are related to each other by

$$\ln \frac{K_{p2}}{K_{p1}} \cong \frac{\bar{h}_R}{R_u} \left(\frac{1}{T_1} - \frac{1}{T_2} \right) \quad \text{or} \quad \ln K_{p2} - \ln K_{p1} \cong \frac{\bar{h}_R}{R_u} \left(\frac{1}{T_1} - \frac{1}{T_2} \right)$$

The \bar{h}_R of the specified reaction at 2400 K is the amount of energy released as one kmol of H_2 is burned in a steady-flow combustion chamber at a temperature of 2400 K, and can be determined from

$$\bar{h}_R = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the H_2O , H_2 and O_2 to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{K}}$ kJ/kmol	$\bar{h}_{2400\text{K}}$ kJ/kmol
H_2O	-241,820	9904	103,508
H_2	0	8468	75,383
O_2	0	8682	83,174

Substituting,

$$\begin{aligned} \bar{h}_R &= 1(-241,820 + 103,508 - 9904) \\ &\quad - 1(0 + 75,383 - 8468) \\ &\quad - 0.5(0 + 83,174 - 8682) \\ &= -252,377 \text{ kJ/kmol} \end{aligned}$$

The K_p value at 2600 K can be estimated from the equation above by using this \bar{h}_R value and the K_p value at 2200 K which is $\ln K_{p1} = 6.768$ or $K_{p1} = 869.6$,

$$\ln(K_{p2}/869.6) \cong \frac{-252,377 \text{ kJ/kmol}}{8.314 \text{ kJ/kmol} \cdot \text{K}} \left(\frac{1}{2200 \text{ K}} - \frac{1}{2600 \text{ K}} \right)$$

$$\ln K_{p2} = 4.645 \quad (\text{Table A - 28: } \ln K_{p2} = 4.648)$$

or

$$K_{p2} = \mathbf{104.1}$$

16-57 The \bar{h}_R value for the dissociation process $\text{CO}_2 \leftrightarrow \text{CO} + 1/2\text{O}_2$ at a specified temperature is to be determined using enthalpy and K_p data.

Assumptions Both the reactants and products are ideal gases.

Analysis (a) The dissociation equation of CO_2 can be expressed as

The \bar{h}_R of the dissociation process of CO_2 at 2200 K is the amount of energy absorbed or released as one kmol of CO_2 dissociates in a steady-flow combustion chamber at a temperature of 2200 K, and can be determined from

$$\bar{h}_R = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the CO , O_2 and CO_2 to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{ K}}$ kJ/kmol	$\bar{h}_{2200\text{ K}}$ kJ/kmol
CO_2	-393,520	9364	112,939
CO	-110,530	8669	72,688
O_2	0	8682	75,484

Substituting,

$$\begin{aligned} \bar{h}_R &= 1(-110,530 + 72,688 - 8669) \\ &\quad + 0.5(0 + 75,484 - 8682) \\ &\quad - 1(-393,520 + 112,939 - 9364) \\ &= \mathbf{276,835\text{ kJ/kmol}} \end{aligned}$$

(b) The \bar{h}_R value at 2200 K can be estimated by using K_p values at 2000 K and 2400 K (the closest two temperatures to 2200 K for which K_p data are available) from Table A-28,

$$\begin{aligned} \ln \frac{K_{P2}}{K_{P1}} &\cong \frac{\bar{h}_R}{R_u} \left(\frac{1}{T_1} - \frac{1}{T_2} \right) \quad \text{or} \quad \ln K_{P2} - \ln K_{P1} \cong \frac{\bar{h}_R}{R_u} \left(\frac{1}{T_1} - \frac{1}{T_2} \right) \\ -3.860 - (-6.635) &\cong \frac{\bar{h}_R}{8.314\text{ kJ/kmol} \cdot \text{K}} \left(\frac{1}{2000\text{ K}} - \frac{1}{2400\text{ K}} \right) \\ \bar{h}_R &\cong \mathbf{276,856\text{ kJ/kmol}} \end{aligned}$$

16-58 The enthalpy of reaction for the equilibrium reaction $\text{CH}_4 + 2\text{O}_2 = \text{CO}_2 + 2\text{H}_2\text{O}$ at 2500 K is to be estimated using enthalpy data and equilibrium constant, K_p data.

Analysis For this problem we use enthalpy and Gibbs function properties from EES.

The K_p value of a reaction at a specified temperature can be determined from the Gibbs function data using

$$K_p = e^{-\Delta G^*(T)/R_u T} \quad \text{or} \quad \ln K_p = -\Delta G^*(T)/R_u T$$

where

$$\Delta G^*(T) = \nu_{\text{CO}_2} \bar{g}_{\text{CO}_2}^*(T) + \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T) - \nu_{\text{CH}_4} \bar{g}_{\text{CH}_4}^*(T) - \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T)$$

At $T_1 = 2500 - 10 = 2490$ K:

$$\begin{aligned} \Delta G_1^*(T) &= \nu_{\text{CO}_2} \bar{g}_{\text{CO}_2}^*(T_1) + \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T_1) - \nu_{\text{CH}_4} \bar{g}_{\text{CH}_4}^*(T_1) - \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T_1) \\ &= 1(-1,075,278) + 2(-831,031) - 1(-722,303) - 2(-611,914) \\ &= -791,208 \text{ kJ/kmol} \end{aligned}$$

At $T_2 = 2500 + 10 = 2510$ K:

$$\begin{aligned} \Delta G_2^*(T) &= \nu_{\text{CO}_2} \bar{g}_{\text{CO}_2}^*(T_2) + \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T_2) - \nu_{\text{CH}_4} \bar{g}_{\text{CH}_4}^*(T_2) - \nu_{\text{O}_2} \bar{g}_{\text{O}_2}^*(T_2) \\ &= 1(-1,081,734) + 2(-836,564) - 1(-728,962) - 2(-617,459) \\ &= -790,981 \text{ kJ/kmol} \end{aligned}$$

The Gibbs functions are obtained from enthalpy and entropy properties using EES. Substituting,

$$K_{p1} = \exp\left(-\frac{-791,208 \text{ kJ/kmol}}{(8.314 \text{ kJ/kmol} \cdot \text{K})(2490 \text{ K})}\right) = 3.966 \times 10^{16}$$

$$K_{p2} = \exp\left(-\frac{-790,981 \text{ kJ/kmol}}{(8.314 \text{ kJ/kmol} \cdot \text{K})(2510 \text{ K})}\right) = 2.893 \times 10^{16}$$

The enthalpy of reaction is determined by using the integrated van't Hoff equation:

$$\begin{aligned} \ln\left(\frac{K_{p2}}{K_{p1}}\right) &= \frac{\bar{h}_R}{R_u} \left(\frac{1}{T_1} - \frac{1}{T_2}\right) \\ \ln\left(\frac{2.893 \times 10^{16}}{3.966 \times 10^{16}}\right) &= \frac{\bar{h}_R}{8.314 \text{ kJ/kmol} \cdot \text{K}} \left(\frac{1}{2490 \text{ K}} - \frac{1}{2510 \text{ K}}\right) \longrightarrow \bar{h}_R = \mathbf{-819,472 \text{ kJ/kmol}} \end{aligned}$$

The enthalpy of reaction can also be determined from an energy balance to be

$$\bar{h}_R = H_P - H_R$$

where

$$H_R = 1\bar{h}_{\text{CH}_4 @ 2500\text{K}} + 2\bar{h}_{\text{O}_2 @ 2500\text{K}} = 106,833 + 2(78,437) = 263,708 \text{ kJ/kmol}$$

$$H_P = 1\bar{h}_{\text{CO}_2 @ 2500\text{K}} + 2\bar{h}_{\text{H}_2\text{O} @ 2500\text{K}} = (-271,531) + 2(-142,117) = -555,765 \text{ kJ/kmol}$$

The enthalpies are obtained from EES. Substituting,

$$\bar{h}_R = H_P - H_R = (-555,765) - (263,708) = \mathbf{-819,472 \text{ kJ/kmol}}$$

which is identical to the value obtained using K_p data.

The EES code for the solution of this problem is given next:

"The reaction temperature is:"

T_reac= 2500 [K]

DELTA T=10 [K]

$$R_u=8.314 \text{ [kJ/kmol-K]}$$

"The assumed equilibrium reaction is $\text{CH}_4 + 2 \text{O}_2 = \text{CO}_2 + 2 \text{H}_2\text{O}$ "

"The following equations provide the specific Gibbs function ($g=h-Ts$) for each component in the product gases as a function of its temperature, T_{reac} , at 1 atm pressure, 101.3 kPa"

"First find K_{P_1} at T_{mDT} "

$$T_{mDT}=T_{\text{reac}}-\text{DELTA}T \text{ [K]}$$

$$K_{P_1} = 3.966E+16$$

$$R_u = 8.314 \text{ [kJ/kmol-K]}$$

$$T_{pDT} = 2510 \text{ [K]}$$

Phase Equilibrium

16-59C No. Because the specific gibbs function of each phase will not be affected by this process; i.e., we will still have $g_f = g_g$.

16-60C Yes. Because the number of independent variables for a two-phase (PH=2), two-component (C=2) mixture is, from the phase rule,

$$IV = C - PH + 2 = 2 - 2 + 2 = 2$$

Therefore, two properties can be changed independently for this mixture. In other words, we can hold the temperature constant and vary the pressure and still be in the two-phase region. Notice that if we had a single component (C=1) two phase system, we would have IV=1, which means that fixing one independent property automatically fixes all the other properties.

11-61C Using solubility data of a solid in a specified liquid, the mass fraction w of the solid A in the liquid at the interface at a specified temperature can be determined from

$$\text{mf}_A = \frac{m_{\text{solid}}}{m_{\text{solid}} + m_{\text{liquid}}}$$

where m_{solid} is the maximum amount of solid dissolved in the liquid of mass m_{liquid} at the specified temperature.

11-62C The molar concentration C_i of the gas species i in the solid at the interface $C_{i, \text{solid side}}(0)$ is proportional to the *partial pressure* of the species i in the gas $P_{i, \text{gas side}}(0)$ on the gas side of the interface, and is determined from

$$C_{i, \text{solid side}}(0) = S \times P_{i, \text{gas side}}(0) \quad (\text{kmol/m}^3)$$

where S is the *solubility* of the gas in that solid at the specified temperature.

11-63C Using Henry's constant data for a gas dissolved in a liquid, the mole fraction of the gas dissolved in the liquid at the interface at a specified temperature can be determined from Henry's law expressed as

$$y_{i, \text{liquid side}}(0) = \frac{P_{i, \text{gas side}}(0)}{H}$$

where H is *Henry's constant* and $P_{i, \text{gas side}}(0)$ is the partial pressure of the gas i at the gas side of the interface. This relation is applicable for dilute solutions (gases that are weakly soluble in liquids).

16-64E The maximum partial pressure of the water evaporated into the air as it emerges from a porous media is to be determined.

Assumptions The air and water-air solution behave as ideal solutions so that Raoult's law may be used.

Analysis The saturation temperature of water at 70°F is

$$P_{\text{sat}@70^\circ\text{F}} = 0.36334 \text{ psia}$$

Since the mole fraction of the air in the liquid water is essentially zero,

$$P_{v,\text{max}} = 1 \times P_{\text{sat}@70^\circ\text{F}} = \mathbf{0.36334 \text{ psia}}$$

16-65E Water is sprayed into air, and the falling water droplets are collected in a container. The mass and mole fractions of air dissolved in the water are to be determined.

Assumptions 1 Both the air and water vapor are ideal gases. **2** Air is saturated since water is constantly sprayed into it. **3** Air is weakly soluble in water and thus Henry's law is applicable.

Properties The saturation pressure of water at 80°F is 0.5075 psia (Table A-4E). Henry's constant for air dissolved in water at 80°F (300 K) is given in Table 16-2 to be $H = 74,000 \text{ bar}$. Molar masses of dry air and water are 29 and 18 lbm / lbmol, respectively (Table A-1).

Analysis Noting that air is saturated, the partial pressure of water vapor

in the air will simply be the saturation pressure of water at 80°F,

$$P_{\text{vapor}} = P_{\text{sat}@80^\circ\text{F}} = 0.5075 \text{ psia}$$

Then the partial pressure of dry air becomes

$$P_{\text{dry air}} = P - P_{\text{vapor}} = 14.3 - 0.5075 = 13.793 \text{ psia}$$

From Henry's law, the mole fraction of air in the water is determined to be

$$y_{\text{dry air, liquid side}} = \frac{P_{\text{dry air, gasside}}}{H} = \frac{13.793 \text{ psia} (1 \text{ atm} / 14.696 \text{ psia})}{74,000 \text{ bar} (1 \text{ atm} / 1.01325 \text{ bar})} = \mathbf{1.29 \times 10^{-5}}$$

which is very small, as expected.

The mass and mole fractions of a mixture are related to each other by

$$\text{mf}_i = \frac{m_i}{m_m} = \frac{N_i M_i}{N_m M_m} = y_i \frac{M_i}{M_m}$$

where the apparent molar mass of the liquid water - air mixture is

$$\begin{aligned} M_m &= \sum y_i M_i = y_{\text{liquid water}} M_{\text{water}} + y_{\text{dry air}} M_{\text{dry air}} \\ &\cong 1 \times 18.0 + 0 \times 29.0 \cong 18.0 \text{ kg/kmol} \end{aligned}$$

Then the mass fraction of dissolved air in liquid water becomes

$$\text{mf}_{\text{dry air, liquid side}} = y_{\text{dry air, liquid side}} \frac{M_{\text{dry air}}}{M_m} = (1.29 \times 10^{-5}) \frac{29}{18} = \mathbf{2.08 \times 10^{-5}}$$

16-66 It is to be shown that a saturated liquid-vapor mixture of refrigerant-134a at -10°C satisfies the criterion for phase equilibrium.

Analysis Using the definition of Gibbs function and enthalpy and entropy data from Table A-11,

$$g_f = h_f - Ts_f = (38.53 \text{ kJ/kg}) - (263.15 \text{ K})(0.15496 \text{ kJ/kg} \cdot \text{K}) = -2.248 \text{ kJ/kg}$$

$$g_g = h_g - Ts_g = (244.55 \text{ kJ/kg}) - (263.15 \text{ K})(0.93782 \text{ kJ/kg} \cdot \text{K}) = -2.234 \text{ kJ/kg}$$

which are sufficiently close. Therefore, the criterion for phase equilibrium is satisfied.

16-67 It is to be shown that a mixture of saturated liquid water and saturated water vapor at 300 kPa satisfies the criterion for phase equilibrium.

Analysis The saturation temperature at 300 kPa is 406.7 K. Using the definition of Gibbs function and enthalpy and entropy data from Table A-5,

$$g_f = h_f - Ts_f = (561.43 \text{ kJ/kg}) - (406.7 \text{ K})(1.6717 \text{ kJ/kg} \cdot \text{K}) = -118.5 \text{ kJ/kg}$$

$$g_g = h_g - Ts_g = (2724.9 \text{ kJ/kg}) - (406.7 \text{ K})(6.9917 \text{ kJ/kg} \cdot \text{K}) = -118.6 \text{ kJ/kg}$$

which are practically same. Therefore, the criterion for phase equilibrium is satisfied.

16-68 The values of the Gibbs function for saturated refrigerant-134a at 280 kPa are to be calculated.

Analysis The saturation temperature of R-134a at 280 kPa is -1.25°C (Table A-12). Obtaining other properties from Table A-12, the Gibbs function for the liquid phase is,

$$g_f = h_f - Ts_f = 50.16 \text{ kJ/kg} - (-1.25 + 273.15 \text{ K})(0.19822 \text{ kJ/kg} \cdot \text{K}) = \mathbf{-3.735 \text{ kJ/kg}}$$

For the vapor phase,

$$g_g = h_g - Ts_g = 249.77 \text{ kJ/kg} - (-1.25 + 273.15 \text{ K})(0.93228 \text{ kJ/kg} \cdot \text{K}) = \mathbf{-3.721 \text{ kJ/kg}}$$

The results agree and demonstrate that phase equilibrium exists.

R-134a 280 kPa $x = 0.70$

16-69E The values of the Gibbs function for saturated steam at 500°F as a saturated liquid, saturated vapor, and a mixture of liquid and vapor are to be calculated.

Analysis Obtaining properties from Table A-4E, the Gibbs function for the liquid phase is,

$$g_f = h_f - Ts_f = 487.89 \text{ Btu/lbm} - (959.67 \text{ R})(0.6890 \text{ Btu/lbm} \cdot \text{R}) = \mathbf{-173.3 \text{ Btu/lbm}}$$

For the vapor phase,

$$g_g = h_g - Ts_g = 1202.3 \text{ Btu/lbm} - (959.67 \text{ R})(1.4334 \text{ Btu/lbm} \cdot \text{R}) = \mathbf{-173.3 \text{ Btu/lbm}}$$

For the saturated mixture with a quality of 40%,

$$h = h_f + xh_{fg} = 487.89 \text{ Btu/lbm} + (0.40)(714.44 \text{ Btu/lbm}) = 773.67 \text{ Btu/lbm}$$

$$s = s_f + xs_{fg} = 0.6890 \text{ Btu/lbm} \cdot \text{R} + (0.40)(0.7445 \text{ Btu/lbm} \cdot \text{R}) = 0.9868 \text{ Btu/lbm} \cdot \text{R}$$

$$g = h - Ts = 773.67 \text{ Btu/lbm} - (959.67 \text{ R})(0.9868 \text{ Btu/lbm} \cdot \text{R}) = \mathbf{-173.3 \text{ Btu/lbm}}$$

The results agree and demonstrate that phase equilibrium exists.

Steam
500°F

16-70 A liquid-vapor mixture of ammonia and water in equilibrium at a specified temperature is considered. The pressure of ammonia is to be determined for two compositions of the liquid phase.

Assumptions The mixture is ideal and thus Raoult's law is applicable.

Analysis According to Raoult's law, when the mole fraction of the ammonia liquid is 20%,

$$P_{\text{NH}_3} = y_{f,\text{NH}_3} P_{\text{sat},\text{NH}_3}(T) = 0.20(615.3 \text{ kPa}) = \mathbf{123.1 \text{ kPa}}$$

When the mole fraction of the ammonia liquid is 80%,

$$P_{\text{NH}_3} = y_{f,\text{NH}_3} P_{\text{sat},\text{NH}_3}(T) = 0.80(615.3 \text{ kPa}) = \mathbf{492.2 \text{ kPa}}$$

16-71 Using the liquid-vapor equilibrium diagram of an oxygen-nitrogen mixture, the composition of each phase at a specified temperature and pressure is to be determined.

Analysis From the equilibrium diagram (Fig. 16-21) we read

Liquid: 30% N₂ and 70% O₂

Vapor: 67% N₂ and 33% O₂

16-72 Using the liquid-vapor equilibrium diagram of an oxygen-nitrogen mixture at a specified pressure, the temperature is to be determined for a specified composition of the vapor phase.

Analysis From the equilibrium diagram (Fig. 16-21) we read

$$T = \mathbf{82 \text{ K.}}$$

16-73 Using the liquid-vapor equilibrium diagram of an oxygen-nitrogen mixture at a specified pressure, the mass of the oxygen in the liquid and gaseous phases is to be determined for a specified composition of the mixture.

Properties The molar masses of O_2 is 32 kg/kmol and that of N_2 is 28 kg/kmol (Table A-1).

Analysis From the equilibrium diagram (Fig. 16-21) at $T = 84$ K, the oxygen mole fraction in the vapor phase is 34% and that in the liquid phase is 70%. That is,

$$y_{f,O_2} = 0.70 \quad \text{and} \quad y_{g,O_2} = 0.34$$

The mole numbers are

$$N_{O_2} = \frac{m_{O_2}}{M_{O_2}} = \frac{30 \text{ kg}}{32 \text{ kg/kmol}} = 0.9375 \text{ kmol}$$

$$N_{N_2} = \frac{m_{N_2}}{M_{N_2}} = \frac{40 \text{ kg}}{28 \text{ kg/kmol}} = 1.429 \text{ kmol}$$

$$N_{\text{total}} = 0.9375 + 1.429 = 2.366 \text{ kmol}$$

The total number of moles in this system is

$$N_f + N_g = 2.366 \quad (1)$$

The total number of moles of oxygen in this system is

$$0.7N_f + 0.34N_g = 0.9375 \quad (2)$$

Solving equations (1) and (2) simultaneously, we obtain

$$N_f = 0.3696$$

$$N_g = 1.996$$

Then, the mass of oxygen in the liquid and vapor phases is

$$m_{f,O_2} = y_{f,O_2} N_f M_{O_2} = (0.7)(0.3696 \text{ kmol})(32 \text{ kg/kmol}) = \mathbf{8.28 \text{ kg}}$$

$$m_{g,O_2} = y_{g,O_2} N_g M_{O_2} = (0.34)(1.996 \text{ kmol})(32 \text{ kg/kmol}) = \mathbf{21.72 \text{ kg}}$$

16-74 Using the liquid-vapor equilibrium diagram of an oxygen-nitrogen mixture at a specified pressure, the total mass of the liquid phase is to be determined.

Properties The molar masses of O_2 is 32 kg/kmol and that of N_2 is 28 kg/kmol (Table A-1).

Analysis From the equilibrium diagram (Fig. 16-21) at $T = 84$ K, the oxygen mole fraction in the vapor phase is 34% and that in the liquid phase is 70%. That is,

$$y_{f,O_2} = 0.70 \quad \text{and} \quad y_{g,O_2} = 0.34$$

Also,

$$y_{f,N_2} = 0.30 \quad \text{and} \quad y_{g,N_2} = 0.66$$

The mole numbers are

$$N_{O_2} = \frac{m_{O_2}}{M_{O_2}} = \frac{30 \text{ kg}}{32 \text{ kg/kmol}} = 0.9375 \text{ kmol}$$

$$N_{N_2} = \frac{m_{N_2}}{M_{N_2}} = \frac{40 \text{ kg}}{28 \text{ kg/kmol}} = 1.429 \text{ kmol}$$

$$N_{\text{total}} = 0.9375 + 1.429 = 2.366 \text{ kmol}$$

The total number of moles in this system is

$$N_f + N_g = 2.366 \quad (1)$$

The total number of moles of oxygen in this system is

$$0.7N_f + 0.34N_g = 0.9375 \quad (2)$$

Solving equations (1) and (2) simultaneously, we obtain

$$N_f = 0.3696$$

$$N_g = 1.996$$

The total mass of liquid in the mixture is then

$$\begin{aligned} m_{f,\text{total}} &= m_{f,O_2} + m_{f,N_2} \\ &= y_{f,O_2} N_f M_{O_2} + y_{f,N_2} N_f M_{N_2} \\ &= (0.7)(0.3696 \text{ kmol})(32 \text{ kg/kmol}) + (0.3)(0.3696 \text{ kmol})(28 \text{ kg/kmol}) \\ &= \mathbf{11.38 \text{ kg}} \end{aligned}$$

16-75 A rubber wall separates O_2 and N_2 gases. The molar concentrations of O_2 and N_2 in the wall are to be determined.

Assumptions The O_2 and N_2 gases are in phase equilibrium with the rubber wall.

Properties The molar mass of oxygen and nitrogen are 32.0 and 28.0 kg/kmol, respectively (Table A-1). The solubility of oxygen and nitrogen in rubber at 298 K are 0.00312 and 0.00156 kmol/m³·bar, respectively (Table 16-3).

Analysis Noting that 500 kPa = 5 bar, the molar densities of oxygen and nitrogen in the rubber wall are determined to be

$$\begin{aligned} C_{O_2, \text{solidside}}(0) &= S \times P_{O_2, \text{gasside}} \\ &= (0.00312 \text{ kmol/m}^3 \cdot \text{bar})(5 \text{ bar}) \\ &= \mathbf{0.0156 \text{ kmol/m}^3} \end{aligned}$$

$$\begin{aligned} C_{N_2, \text{solidside}}(0) &= S \times P_{N_2, \text{gasside}} \\ &= (0.00156 \text{ kmol/m}^3 \cdot \text{bar})(5 \text{ bar}) \\ &= \mathbf{0.00780 \text{ kmol/m}^3} \end{aligned}$$

That is, there will be 0.0156 kmol of O_2 and 0.00780 kmol of N_2 gas in each m³ volume of the rubber wall.

16-76 A rubber plate is exposed to nitrogen. The molar and mass density of nitrogen in the iron at the interface is to be determined.

Assumptions Rubber and nitrogen are in thermodynamic equilibrium at the interface.

Properties The molar mass of nitrogen is $M = 28.0$ kg/kmol (Table A-1). The solubility of nitrogen in rubber at 298 K is 0.00156 kmol/m³·bar (Table 16-3).

Analysis Noting that 250 kPa = 2.5 bar, the molar density of nitrogen in the rubber at the interface is determined to be

$$\begin{aligned} C_{N_2, \text{solidside}}(0) &= S \times P_{N_2, \text{gasside}} \\ &= (0.00156 \text{ kmol/m}^3 \cdot \text{bar})(2.5 \text{ bar}) \\ &= \mathbf{0.0039 \text{ kmol/m}^3} \end{aligned}$$

It corresponds to a mass density of

$$\begin{aligned} \rho_{N_2, \text{solidside}}(0) &= C_{N_2, \text{solidside}}(0) M_{N_2} \\ &= (0.0039 \text{ kmol/m}^3)(28 \text{ kg/kmol}) \\ &= \mathbf{0.1092 \text{ kg/m}^3} \end{aligned}$$

That is, there will be 0.0039 kmol (or 0.1092 kg) of N_2 gas in each m³ volume of iron adjacent to the interface.

16-77 A liquid-vapor mixture of ammonia and water in equilibrium at a specified temperature is considered. The composition of the liquid phase is given. The composition of the vapor phase is to be determined.

Assumptions The mixture is ideal and thus Raoult's law is applicable.

Properties At 30°C, $P_{\text{sat,H}_2\text{O}} = 4.247 \text{ kPa}$ and $P_{\text{sat,NH}_3} = 1167.4 \text{ kPa}$.

Analysis The vapor pressures are

$$P_{\text{H}_2\text{O}} = y_{f,\text{H}_2\text{O}} P_{\text{sat,H}_2\text{O}}(T) = 0.40(4.247 \text{ kPa}) = 1.70 \text{ kPa}$$

$$P_{\text{NH}_3} = y_{f,\text{NH}_3} P_{\text{sat,NH}_3}(T) = 0.60(1167.4 \text{ kPa}) = 700.44 \text{ kPa}$$

Thus the total pressure of the mixture is

$$P_{\text{total}} = P_{\text{H}_2\text{O}} + P_{\text{NH}_3} = (1.70 + 700.44) \text{ kPa} = 702.1 \text{ kPa}$$

Then the mole fractions in the vapor phase become

$$y_{g,\text{H}_2\text{O}} = \frac{P_{\text{H}_2\text{O}}}{P_{\text{total}}} = \frac{1.70 \text{ kPa}}{702.1 \text{ kPa}} = \mathbf{0.0024} \text{ or } 0.24\%$$

$$y_{g,\text{NH}_3} = \frac{P_{\text{NH}_3}}{P_{\text{total}}} = \frac{700.44 \text{ kPa}}{702.1 \text{ kPa}} = \mathbf{0.9976} \text{ or } 99.76\%$$

16-78 An ammonia-water absorption refrigeration unit is considered. The operating pressures in the generator and absorber, and the mole fractions of the ammonia in the strong liquid mixture being pumped from the absorber and the weak liquid solution being drained from the generator are to be determined.

Assumptions The mixture is ideal and thus Raoult's law is applicable.

Properties At 0°C, $P_{\text{sat,H}_2\text{O}} = 0.6112 \text{ kPa}$ and at 46°C, $P_{\text{sat,H}_2\text{O}} = 10.10 \text{ kPa}$ (Table A-4). The saturation pressures of ammonia at the same temperatures are given to be 430.6 kPa and 1830.2 kPa, respectively.

Analysis According to Raoult's law, the partial pressures of ammonia and water are given by

$$P_{g,\text{NH}_3} = y_{f,\text{NH}_3} P_{\text{sat,NH}_3}$$

$$P_{g,\text{H}_2\text{O}} = y_{f,\text{H}_2\text{O}} P_{\text{sat,H}_2\text{O}} = (1 - y_{f,\text{NH}_3}) P_{\text{sat,H}_2\text{O}}$$

Using Dalton's partial pressure model for ideal gas mixtures, the mole fraction of the ammonia in the vapor mixture is

$$y_{g,\text{NH}_3} = \frac{y_{f,\text{NH}_3} P_{\text{sat,NH}_3}}{y_{f,\text{NH}_3} P_{\text{sat,NH}_3} + (1 - y_{f,\text{NH}_3}) P_{\text{sat,H}_2\text{O}}}$$

$$0.96 = \frac{430.6 y_{f,\text{NH}_3}}{430.6 y_{f,\text{NH}_3} + 0.6112(1 - y_{f,\text{NH}_3})} \longrightarrow y_{f,\text{NH}_3} = \mathbf{0.03294}$$

Then,

$$P = y_{f,\text{NH}_3} P_{\text{sat,NH}_3} + (1 - y_{f,\text{NH}_3}) P_{\text{sat,H}_2\text{O}}$$

$$= (0.03294)(430.6) + (1 - 0.03294)(0.6112) = \mathbf{14.78 \text{ kPa}}$$

Performing the similar calculations for the regenerator,

$$0.96 = \frac{1830.2 y_{f,\text{NH}_3}}{1830.2 y_{f,\text{NH}_3} + 10.10(1 - y_{f,\text{NH}_3})} \longrightarrow y_{f,\text{NH}_3} = \mathbf{0.1170}$$

$$P = (0.1170)(1830.2) + (1 - 0.1170)(10.10) = \mathbf{223.1 \text{ kPa}}$$

16-79 An ammonia-water absorption refrigeration unit is considered. The operating pressures in the generator and absorber, and the mole fractions of the ammonia in the strong liquid mixture being pumped from the absorber and the weak liquid solution being drained from the generator are to be determined.

Assumptions The mixture is ideal and thus Raoult's law is applicable.

Properties At 6°C, $P_{\text{sat,H}_2\text{O}} = 0.9353 \text{ kPa}$ and at 40°C, $P_{\text{sat,H}_2\text{O}} = 7.3851 \text{ kPa}$ (Table A-4 or EES). The saturation pressures of ammonia at the same temperatures are given to be 534.8 kPa and 1556.7 kPa, respectively.

Analysis According to Raoult's law, the partial pressures of ammonia and water are given by

$$P_{\text{g,NH}_3} = y_{f,\text{NH}_3} P_{\text{sat,NH}_3}$$

$$P_{\text{g,H}_2\text{O}} = y_{f,\text{H}_2\text{O}} P_{\text{sat,H}_2\text{O}} = (1 - y_{f,\text{NH}_3}) P_{\text{sat,H}_2\text{O}}$$

Using Dalton's partial pressure model for ideal gas mixtures, the mole fraction of the ammonia in the vapor mixture is

$$y_{\text{g,NH}_3} = \frac{y_{f,\text{NH}_3} P_{\text{sat,NH}_3}}{y_{f,\text{NH}_3} P_{\text{sat,NH}_3} + (1 - y_{f,\text{NH}_3}) P_{\text{sat,H}_2\text{O}}}$$

$$0.96 = \frac{534.8 y_{f,\text{NH}_3}}{534.8 y_{f,\text{NH}_3} + 0.9353(1 - y_{f,\text{NH}_3})} \longrightarrow y_{f,\text{NH}_3} = \mathbf{0.04028}$$

Then,

$$P = y_{f,\text{NH}_3} P_{\text{sat,NH}_3} + (1 - y_{f,\text{NH}_3}) P_{\text{sat,H}_2\text{O}}$$

$$= (0.04028)(534.8) + (1 - 0.04028)(0.9353) = \mathbf{22.44 \text{ kPa}}$$

Performing the similar calculations for the regenerator,

$$0.96 = \frac{1556.7 y_{f,\text{NH}_3}}{1556.7 y_{f,\text{NH}_3} + 7.3851(1 - y_{f,\text{NH}_3})} \longrightarrow y_{f,\text{NH}_3} = \mathbf{0.1022}$$

$$P = (0.1022)(1556.7) + (1 - 0.1022)(7.3851) = \mathbf{165.7 \text{ kPa}}$$

16-80 A liquid mixture of water and R-134a is considered. The mole fraction of the water and R-134a vapor are to be determined.

Assumptions The mixture is ideal and thus Raoult's law is applicable.

Properties At 20°C, $P_{\text{sat,H}_2\text{O}} = 2.3392 \text{ kPa}$ and $P_{\text{sat,R}} = 572.07 \text{ kPa}$ (Tables A-4, A-11). The molar masses of water and R-134a are 18.015 and 102.03 kg/kmol, respectively (Table A-1).

Analysis The mole fraction of the water in the liquid mixture is

$$y_{f,\text{H}_2\text{O}} = \frac{N_{f,\text{H}_2\text{O}}}{N_{\text{total}}} = \frac{\text{mf}_{f,\text{H}_2\text{O}} / M_{\text{H}_2\text{O}}}{(\text{mf}_{f,\text{H}_2\text{O}} / M_{\text{H}_2\text{O}}) + (\text{mf}_{f,\text{R}} / M_{\text{R}})}$$

$$= \frac{0.9 / 18.015}{(0.9 / 18.015) + (0.1 / 102.03)} = 0.9808$$

<p>H₂O + R-134a 20°C</p>

According to Raoult's law, the partial pressures of R-134a and water in the vapor mixture are

$$P_{g,\text{R}} = y_{f,\text{R}} P_{\text{sat,R}} = (1 - 0.9808)(572.07 \text{ kPa}) = 10.98 \text{ kPa}$$

$$P_{g,\text{H}_2\text{O}} = y_{f,\text{H}_2\text{O}} P_{\text{sat,H}_2\text{O}} = (0.9808)(2.3392 \text{ kPa}) = 2.294 \text{ kPa}$$

The total pressure of the vapor mixture is then

$$P_{\text{total}} = P_{g,\text{R}} + P_{g,\text{H}_2\text{O}} = 10.98 + 2.294 = 13.274 \text{ kPa}$$

Based on Dalton's partial pressure model for ideal gases, the mole fractions in the vapor phase are

$$y_{g,\text{H}_2\text{O}} = \frac{P_{g,\text{H}_2\text{O}}}{P_{\text{total}}} = \frac{2.294 \text{ kPa}}{13.274 \text{ kPa}} = \mathbf{0.1728}$$

$$y_{g,\text{R}} = \frac{P_{g,\text{R}}}{P_{\text{total}}} = \frac{10.98 \text{ kPa}}{13.274 \text{ kPa}} = \mathbf{0.8272}$$

16-81 A glass of water is left in a room. The mole fraction of the water vapor in the air and the mole fraction of air in the water are to be determined when the water and the air are in thermal and phase equilibrium.

Assumptions **1** Both the air and water vapor are ideal gases. **2** Air is saturated since the humidity is 100 percent. **3** Air is weakly soluble in water and thus Henry's law is applicable.

Properties The saturation pressure of water at 27°C is 3.568 kPa (Table A-4). Henry's constant for air dissolved in water at 27°C (300 K) is given in Table 16-2 to be $H = 74,000$ bar. Molar masses of dry air and water are 29 and 18 kg/kmol, respectively (Table A-1).

Analysis (a) Noting that air is saturated, the partial pressure of water vapor in the air will simply be the saturation pressure of water at 27°C,

$$P_{\text{vapor}} = P_{\text{sat @ 27°C}} = 3.568 \text{ kPa} \quad (\text{Table A-4 or EES})$$

Assuming both the air and vapor to be ideal gases, the mole fraction of water vapor in the air is determined to be

$$y_{\text{vapor}} = \frac{P_{\text{vapor}}}{P} = \frac{3.568 \text{ kPa}}{97 \text{ kPa}} = \mathbf{0.0368}$$

(b) Noting that the total pressure is 97 kPa, the partial pressure of dry air is

$$P_{\text{dry air}} = P - P_{\text{vapor}} = 97 - 3.568 = 93.43 \text{ kPa} = 0.9343 \text{ bar}$$

From Henry's law, the mole fraction of air in the water is determined to be

$$y_{\text{dry air, liquid side}} = \frac{P_{\text{dry air, gas side}}}{H} = \frac{0.9343 \text{ bar}}{74,000 \text{ bar}} = \mathbf{1.26 \times 10^{-5}}$$

Discussion The amount of air dissolved in water is very small, as expected.

16-82 A carbonated drink in a bottle is considered. Assuming the gas space above the liquid consists of a saturated mixture of CO₂ and water vapor and treating the drink as a water, determine the mole fraction of the water vapor in the CO₂ gas and the mass of dissolved CO₂ in a 300 ml drink are to be determined when the water and the CO₂ gas are in thermal and phase equilibrium.

Assumptions 1 The liquid drink can be treated as water. **2** Both the CO₂ and the water vapor are ideal gases. **3** The CO₂ gas and water vapor in the bottle form a saturated mixture. **4** The CO₂ is weakly soluble in water and thus Henry's law is applicable.

Properties The saturation pressure of water at 27°C is 3.568 kPa (Table A-4). Henry's constant for CO₂ dissolved in water at 27°C (300 K) is given in Table 16-2 to be $H = 1710$ bar. Molar masses of CO₂ and water are 44 and 18 kg/kmol, respectively (Table A-1).

Analysis (a) Noting that the CO₂ gas in the bottle is saturated, the partial pressure of water vapor in the air will simply be the saturation pressure of water at 27°C,

$$P_{\text{vapor}} = P_{\text{sat @ 27°C}} = 3.568 \text{ kPa} \quad (\text{more accurate EES value compared to interpolation value from Table A-4})$$

Assuming both CO₂ and vapor to be ideal gases, the mole fraction of water vapor in the CO₂ gas becomes

$$y_{\text{vapor}} = \frac{P_{\text{vapor}}}{P} = \frac{3.568 \text{ kPa}}{115 \text{ kPa}} = \mathbf{0.0310}$$

(b) Noting that the total pressure is 115 kPa, the partial pressure of CO₂ is

$$P_{\text{CO}_2 \text{ gas}} = P - P_{\text{vapor}} = 115 - 3.568 = 111.4 \text{ kPa} = 1.114 \text{ bar}$$

From Henry's law, the mole fraction of CO₂ in the drink is determined to be

$$y_{\text{CO}_2, \text{liquid side}} = \frac{P_{\text{CO}_2 \text{ gas side}}}{H} = \frac{1.114 \text{ bar}}{1710 \text{ bar}} = \mathbf{6.52 \times 10^{-4}}$$

Then the mole fraction of water in the drink becomes

$$y_{\text{water, liquid side}} = 1 - y_{\text{CO}_2, \text{liquid side}} = 1 - 6.52 \times 10^{-4} = 0.9993$$

The mass and mole fractions of a mixture are related to each other by

$$mf_i = \frac{m_i}{m_m} = \frac{N_i M_i}{N_m M_m} = y_i \frac{M_i}{M_m}$$

where the apparent molar mass of the drink (liquid water - CO₂ mixture) is

$$M_m = \sum y_i M_i = y_{\text{liquid water}} M_{\text{water}} + y_{\text{CO}_2} M_{\text{CO}_2} = 0.9993 \times 18.0 + (6.52 \times 10^{-4}) \times 44 = 18.03 \text{ kg/kmol}$$

Then the mass fraction of dissolved CO₂ gas in liquid water becomes

$$mf_{\text{CO}_2, \text{liquid side}} = y_{\text{CO}_2, \text{liquid side}} \frac{M_{\text{CO}_2}}{M_m} = 6.52 \times 10^{-4} \frac{44}{18.03} = 0.00159$$

Therefore, the mass of dissolved CO₂ in a 300 ml \approx 300 g drink is

$$m_{\text{CO}_2} = mf_{\text{CO}_2} m_m = (0.00159)(300 \text{ g}) = \mathbf{0.477 \text{ g}}$$

Review Problems

16-83 The mole fraction of argon that ionizes at a specified temperature and pressure is to be determined.

Assumptions All components behave as ideal gases.

Analysis The stoichiometric and actual reactions can be written as

Stoichiometric: $\text{Ar} \Leftrightarrow \text{Ar}^+ + \text{e}^-$ (thus $\nu_{\text{Ar}} = 1$, $\nu_{\text{Ar}^+} = 1$ and $\nu_{\text{e}^-} = 1$)

Actual: $\text{Ar} \longrightarrow \underbrace{x\text{Ar}}_{\text{react.}} + \underbrace{y\text{Ar}^+ + ye^-}_{\text{products}}$

Ar balance: $1 = x + y$ or $y = 1 - x$

Total number of moles: $N_{\text{total}} = x + 2y = 2 - x$

The equilibrium constant relation becomes

$$K_p = \frac{N_{\text{Ar}}^{\nu_{\text{Ar}}} N_{\text{e}^-}^{\nu_{\text{e}^-}}}{N_{\text{Ar}^+}^{\nu_{\text{Ar}^+}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{Ar}^+} + \nu_{\text{e}^-} - \nu_{\text{Ar}})} = \frac{y^2}{x} \left(\frac{P}{N_{\text{total}}} \right)^{1+1-1}$$

Substituting,

$$0.00042 = \frac{(1-x)^2}{x} \left(\frac{0.35}{2-x} \right)$$

Solving for x ,

$$x = 0.965$$

Thus the fraction of Ar which dissociates into Ar^+ and e^- is

$$1 - 0.965 = 0.035 \quad \text{or} \quad \mathbf{3.5\%}$$

16-84 The equilibrium constant of the dissociation process $O_2 \leftrightarrow 2O$ is given in Table A-28 at different temperatures. The value at a given temperature is to be verified using Gibbs function data.

Analysis The K_p value of a reaction at a specified temperature can be determined from the Gibbs function data using

$$K_p = e^{-\Delta G^*(T)/R_u T} \quad \text{or} \quad \ln K_p = -\Delta G^*(T) / R_u T$$

where

$$\begin{aligned} \Delta G^*(T) &= \nu_O \bar{g}_O^*(T) - \nu_{O_2} \bar{g}_{O_2}^*(T) \\ &= \nu_O (\bar{h} - T\bar{s})_O - \nu_{O_2} (\bar{h} - T\bar{s})_{O_2} \\ &= \nu_O [(\bar{h}_f + \bar{h}_{2000} - \bar{h}_{298}) - T\bar{s}]_O - \nu_{O_2} [(\bar{h}_f + \bar{h}_{2000} - \bar{h}_{298}) - T\bar{s}]_{O_2} \\ &= 2 \times (249,190 + 42,564 - 6852 - 2000 \times 201.135) \\ &\quad - 1 \times (0 + 67,881 - 8682 - 2000 \times 268.655) \\ &= 243,375 \text{ kJ/kmol} \end{aligned}$$

Substituting,

$$\ln K_p = -(243,375 \text{ kJ/kmol}) / [(8.314 \text{ kJ/kmol} \cdot \text{K})(2000 \text{ K})] = -14.636$$

or

$$K_p = 4.4 \times 10^{-7} \quad (\text{Table A-28: } \ln K_p = -14.622)$$

16-85 The equilibrium constant for the reaction $CH_4 + 2O_2 \leftrightarrow CO_2 + 2H_2O$ at 100 kPa and 2000 K is to be determined.

Assumptions 1 The constituents of the mixture are ideal gases.

Analysis This is a simultaneous reaction. We can begin with the dissociation of methane and carbon dioxide,

When these two reactions are summed and the common carbon term cancelled, the result is

Next, we include the water dissociation reaction (Table A-28),

which when summed with the previous reaction and the common hydrogen term is cancelled yields

Then,

$$\ln K_p = \mathbf{32.282}$$

16-86 A glass of water is left in a room. The mole fraction of the water vapor in the air at the water surface and far from the surface as well as the mole fraction of air in the water near the surface are to be determined when the water and the air are at the same temperature.

Assumptions 1 Both the air and water vapor are ideal gases. **2** Air is weakly soluble in water and thus Henry's law is applicable.

Properties The saturation pressure of water at 25°C is 3.170 kPa (Table A-4). Henry's constant for air dissolved in water at 25°C (298 K) is given in Table 16-2 to be $H = 71,600$ bar. Molar masses of dry air and water are 29 and 18 kg/kmol, respectively (Table A-1).

Analysis (a) Noting that the relative humidity of air is 70%, the partial pressure of water vapor in the air far from the water surface will be

$$P_{v, \text{room air}} = \phi P_{\text{sat @ } 25^\circ\text{C}} = (0.7)(3.170 \text{ kPa}) = 2.219 \text{ kPa}$$

Assuming both the air and vapor to be ideal gases, the mole fraction of water vapor in the room air is

$$y_{\text{vapor}} = \frac{P_{\text{vapor}}}{P} = \frac{2.219 \text{ kPa}}{100 \text{ kPa}} = \mathbf{0.0222} \quad (\text{or } \mathbf{2.22\%})$$

(b) Noting that air at the water surface is saturated, the partial pressure of water vapor in the air near the surface will simply be the saturation pressure of water at 25°C, $P_{v, \text{interface}} = P_{\text{sat @ } 25^\circ\text{C}} = 3.170 \text{ kPa}$. Then the mole fraction of water vapor in the air at the interface becomes

$$y_{v, \text{surface}} = \frac{P_{v, \text{surface}}}{P} = \frac{3.170 \text{ kPa}}{100 \text{ kPa}} = \mathbf{0.0317} \quad (\text{or } \mathbf{3.17\%})$$

(c) Noting that the total pressure is 100 kPa, the partial pressure of dry air at the water surface is

$$P_{\text{air, surface}} = P - P_{v, \text{surface}} = 100 - 3.170 = 96.83 \text{ kPa}$$

From Henry's law, the mole fraction of air in the water is determined to be

$$y_{\text{dry air, liquid side}} = \frac{P_{\text{dry air, gas side}}}{H} = \frac{(96.83/100) \text{ bar}}{71,600 \text{ bar}} = \mathbf{1.35 \times 10^{-5}}$$

Discussion The water cannot remain at the room temperature when the air is not saturated. Therefore, some water will evaporate and the water temperature will drop until a balance is reached between the rate of heat transfer to the water and the rate of evaporation.

16-87 A glass of water is left in a room. The mole fraction of the water vapor in the air at the water surface and far from the surface as well as the mole fraction of air in the water near the surface are to be determined when the water and the air are at the same temperature.

Assumptions 1 Both the air and water vapor are ideal gases. **2** Air is weakly soluble in water and thus Henry's law is applicable.

Properties The saturation pressure of water at 25°C is 3.170 kPa (Table A-4). Henry's constant for air dissolved in water at 25°C (298 K) is given in Table 16-2 to be $H = 71,600$ bar. Molar masses of dry air and water are 29 and 18 kg/kmol, respectively (Table A-1).

Analysis (a) Noting that the relative humidity of air is 40%, the partial pressure of water vapor in the air far from the water surface will be

$$P_{v, \text{room air}} = \phi P_{\text{sat @ } 25^\circ\text{C}} = (0.25)(3.170 \text{ kPa}) = 0.7925 \text{ kPa}$$

Assuming both the air and vapor to be ideal gases, the mole fraction of water vapor in the room air is

$$y_{\text{vapor}} = \frac{P_{\text{vapor}}}{P} = \frac{0.7925 \text{ kPa}}{100 \text{ kPa}} = \mathbf{0.0079} \quad (\text{or } \mathbf{0.79\%})$$

(b) Noting that air at the water surface is saturated, the partial pressure of water vapor in the air near the surface will simply be the saturation pressure of water at 25°C, $P_{v, \text{interface}} = P_{\text{sat @ } 25^\circ\text{C}} = 3.170 \text{ kPa}$. Then the mole fraction of water vapor in the air at the interface becomes

$$y_{v, \text{surface}} = \frac{P_{v, \text{surface}}}{P} = \frac{3.170 \text{ kPa}}{100 \text{ kPa}} = \mathbf{0.0317} \quad (\text{or } \mathbf{3.17\%})$$

(c) Noting that the total pressure is 100 kPa, the partial pressure of dry air at the water surface is

$$P_{\text{air, surface}} = P - P_{v, \text{surface}} = 100 - 3.170 = 96.83 \text{ kPa}$$

From Henry's law, the mole fraction of air in the water is determined to be

$$y_{\text{dry air, liquid side}} = \frac{P_{\text{dry air, gas side}}}{H} = \frac{(96.83/100) \text{ bar}}{71,600 \text{ bar}} = \mathbf{1.35 \times 10^{-5}}$$

Discussion The water cannot remain at the room temperature when the air is not saturated. Therefore, some water will evaporate and the water temperature will drop until a balance is reached between the rate of heat transfer to the water and the rate of evaporation.

16-88 Methane gas is burned with stoichiometric amount of air during a combustion process. The equilibrium composition and the exit temperature are to be determined.

Assumptions 1 The product gases consist of CO_2 , H_2O , CO , N_2 , and O_2 . **2** The constituents of the mixture are ideal gases. **3** This is an adiabatic and steady-flow combustion process.

Analysis (a) The combustion equation of CH_4 with stoichiometric amount of O_2 can be written as

After combustion, there will be no CH_4 present in the combustion chamber, and H_2O will act like an inert gas. The equilibrium equation among CO_2 , CO , and O_2 can be expressed as

and
$$K_p = \frac{N_{\text{CO}}^{\nu_{\text{CO}}} N_{\text{O}_2}^{\nu_{\text{O}_2}}}{N_{\text{CO}_2}^{\nu_{\text{CO}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{CO}} + \nu_{\text{O}_2} - \nu_{\text{CO}_2})}$$

where $N_{\text{total}} = x + (1-x) + (1.5 - 0.5x) + 2 + 7.52 = 12.02 - 0.5x$

Substituting,

$$K_p = \frac{(1-x)(0.5 - 0.5x)^{0.5}}{x} \left(\frac{1}{12.02 - 0.5x} \right)^{1.5-1}$$

The value of K_p depends on temperature of the products, which is yet to be determined. A second relation to determine K_p and x is obtained from the steady-flow energy balance expressed as

$$0 = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R \longrightarrow 0 = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R \bar{h}_f^\circ$$

since the combustion is adiabatic and the reactants enter the combustion chamber at 25°C . Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° , kJ/kmol	$\bar{h}_{298\text{K}}$, kJ/kmol
$\text{CH}_4(\text{g})$	-74,850	--
N_2	0	8669
O_2	0	8682
$\text{H}_2\text{O}(\text{g})$	-241,820	9904
CO	-110,530	8669
CO_2	-393,520	9364

Substituting,

$$\begin{aligned} 0 = & x(-393,520 + \bar{h}_{\text{CO}_2} - 9364) + (1-x)(-110,530 + \bar{h}_{\text{CO}} - 8669) \\ & + 2(-241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904) + (0.5 - 0.5x)(0 + \bar{h}_{\text{O}_2} - 8682) \\ & + 7.52(0 + \bar{h}_{\text{N}_2} - 8669) - 1(-74,850 + h_{298} - h_{298}) - 0 - 0 \end{aligned}$$

which yields

$$x\bar{h}_{\text{CO}_2} + (1-x)\bar{h}_{\text{CO}} + 2\bar{h}_{\text{H}_2\text{O}} + (0.5 - 0.5x)\bar{h}_{\text{O}_2} + 7.52\bar{h}_{\text{N}_2} - 279,344x = 617,329$$

Now we have two equations with two unknowns, T_p and x . The solution is obtained by trial and error by assuming a temperature T_p , calculating the equilibrium composition from the first equation, and then checking to see if the second equation is satisfied. A first guess is obtained by assuming there is no CO in the products, i.e., $x = 1$. It yields $T_p = 2328\text{ K}$. The adiabatic combustion temperature with incomplete combustion will be less.

$$\text{Take } T_p = 2300\text{ K} \longrightarrow \ln K_p = -4.49 \longrightarrow x = 0.870 \longrightarrow \text{RHS} = 641,093$$

$$\text{Take } T_p = 2250\text{ K} \longrightarrow \ln K_p = -4.805 \longrightarrow x = 0.893 \longrightarrow \text{RHS} = 612,755$$

By interpolation, $T_p = 2258\text{ K}$ and $x = 0.889$

Thus the composition of the equilibrium mixture is

16-89 Problem 16-88 is reconsidered. The effect of excess air on the equilibrium composition and the exit temperature by varying the percent excess air from 0 to 200 percent is to be studied.

Analysis The problem is solved using EES, and the solution is given below.

"Often, for nonlinear problems such as this one, good guesses are required to start the solution. First, run the program with zero percent excess air to determine the net heat transfer as a function of T_{prod} . Just press F3 or click on the Solve Table icon. From Plot Window 1, where Q_{net} is plotted vs T_{prod} , determine the value of T_{prod} for $Q_{\text{net}}=0$ by holding down the Shift key and move the cross hairs by moving the mouse. Q_{net} is approximately zero at $T_{\text{prod}} = 2269$ K. From Plot Window 2 at $T_{\text{prod}} = 2269$ K, a, b, and c are approximately 0.89, 0.10, and 0.056, respectively." "For EES to calculate a, b, c, and T_{prod} directly for the adiabatic case, remove the '{ }' in the last line of this window to set $Q_{\text{net}} = 0.0$. Then from the Options menu select Variable Info and set the Guess Values of a, b, c, and T_{prod} to the guess values selected from the Plot Windows. Then press F2 or click on the Calculator icon."

16-90 The equilibrium partial pressure of the carbon dioxide for the reaction $\text{CH}_4 + 2\text{O}_2 \leftrightarrow \text{CO}_2 + 2\text{H}_2\text{O}$ at 450 kPa and 3000 K is to be determined.

Assumptions 1 The equilibrium composition consists of CH_4 , O_2 , CO_2 , and H_2O . **2** The constituents of the mixture are ideal gases.

Analysis This is a simultaneous reaction. We can begin with the dissociation of methane and carbon dioxide,

When these two reactions are summed and the common carbon term cancelled, the result is

Next, we include the water dissociation reaction,

which when summed with the previous reaction and the common hydrogen term is cancelled yields

Then,

$$\ln K_p = 12.356$$

C balance: $1 = x + z \longrightarrow z = 1 - x$

H balance: $4 = 4x + 2m \longrightarrow m = 2 - 2x$

O balance: $4 = 2y + 2z + m \longrightarrow y = 2x$

Total number of moles: $N_{\text{total}} = x + y + z + m = 3$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{\text{CO}_2}^{v_{\text{CO}_2}} N_{\text{H}_2\text{O}}^{v_{\text{H}_2\text{O}}}}{N_{\text{CH}_4}^{v_{\text{CH}_4}} N_{\text{O}_2}^{v_{\text{O}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{v_{\text{CO}_2} + v_{\text{H}_2\text{O}} - v_{\text{CH}_4} - v_{\text{O}_2}}$$

Substituting,

$$e^{12.356} = \frac{(1-x)(2-2x)^2}{x(2x)^2} \left(\frac{450/101.325}{3} \right)^{1+2-1-2}$$

Solving for x ,

$$x = 0.01601$$

Then,

$$y = 2x = 0.03201$$

$$z = 1 - x = 0.98399$$

$$m = 2 - 2x = 1.96799$$

Therefore, the equilibrium composition of the mixture at 3000 K and 450 kPa is

The mole fraction of carbon dioxide is

$$y_{\text{CO}_2} = \frac{0.98399}{3} = 0.3280$$

and the partial pressure of the carbon dioxide in the product mixture is

$$P_{\text{CO}_2} = y_{\text{CO}_2}P = (0.3280)(450 \text{ kPa}) = \mathbf{148 \text{ kPa}}$$

16-91 Methane is heated from a specified state to another state. The amount of heat required is to be determined without and with dissociation cases.

Properties The molar mass and gas constant of methane are 16.043 kg/kmol and 0.5182 kJ/kg·K (Table A-1).

Assumptions 1 The equilibrium composition consists of O₂ and O. **2** The constituents of the mixture are ideal gases.

Analysis (a) An energy balance for the process gives

$$\underbrace{E_{\text{in}} - E_{\text{out}}}_{\substack{\text{Net energy transfer} \\ \text{by heat, work, and mass}}} = \underbrace{\Delta E_{\text{system}}}_{\substack{\text{Change in internal, kinetic,} \\ \text{potential, etc. energies}}}$$

$$Q_{\text{in}} = N(\bar{u}_2 - \bar{u}_1)$$

$$= N[\bar{h}_2 - \bar{h}_1 - R_u(T_2 - T_1)]$$

Using the empirical coefficients of Table A-2c,

$$\bar{h}_2 - \bar{h}_1 = \int_1^2 c_p dT = a(T_2 - T_1) + \frac{b}{2}(T_2^2 - T_1^2) + \frac{c}{3}(T_2^3 - T_1^3) + \frac{d}{4}(T_2^4 - T_1^4)$$

$$= 19.89(1000 - 298) + \frac{0.05024}{2}(1000^2 - 298^2) + \frac{1.269 \times 10^{-5}}{3}(1000^3 - 298^3)$$

$$+ \frac{-11.01 \times 10^{-9}}{4}(1000^4 - 298^4)$$

$$= 38,239 \text{ kJ/kmol}$$

Substituting,

$$Q_{\text{in}} = (10 \text{ kmol})[38,239 \text{ kJ/kmol} - (8.314 \text{ kJ/kmol} \cdot \text{K})(1000 - 298)\text{K}] = \mathbf{324,000 \text{ kJ}}$$

(b) The stoichiometric and actual reactions in this case are

C balance: $1 = x + y \longrightarrow y = 1 - x$

H balance: $4 = 4x + 2z \longrightarrow z = 2 - 2x$

Total number of moles: $N_{\text{total}} = x + y + z = 3 - 2x$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{\text{C}}^{\nu_{\text{C}}} N_{\text{H}_2}^{\nu_{\text{H}_2}}}{N_{\text{CH}_4}^{\nu_{\text{CH}_4}}} \left(\frac{P}{N_{\text{total}}} \right)^{\nu_{\text{C}} + \nu_{\text{H}_2} - \nu_{\text{CH}_4}}$$

From the problem statement, at 1000 K, $\ln K_p = -2.328$. Then,

$$K_p = e^{-2.328} = 0.09749$$

Substituting,

$$0.09749 = \frac{(1-x)(2-2x)^2}{x} \left(\frac{1}{3-2x} \right)^{1+2-1}$$

Solving for x ,

$$x = 0.6414$$

Then,

$$y = 1 - x = 0.3586$$

$$z = 2 - 2x = 0.7172$$

Therefore, the equilibrium composition of the mixture at 1000 K and 1 atm is

The mole fractions are

$$y_{\text{CH}_4} = \frac{N_{\text{CH}_4}}{N_{\text{total}}} = \frac{0.6414}{0.6414 + 0.3586 + 0.7172} = \frac{0.6414}{1.7172} = 0.3735$$

$$y_{\text{C}} = \frac{N_{\text{C}}}{N_{\text{total}}} = \frac{0.3586}{1.7172} = 0.2088$$

$$y_{\text{H}_2} = \frac{N_{\text{H}_2}}{N_{\text{total}}} = \frac{0.7172}{1.7172} = 0.4177$$

The heat transfer can be determined from

$$\begin{aligned} Q_{\text{in}} &= N(y_{\text{CH}_4}c_{\nu,\text{CH}_4}T_2 + y_{\text{H}_2}c_{\nu,\text{H}_2}T_2 + y_{\text{C}}c_{\nu,\text{C}}T_2) - Nc_{\nu,\text{CH}_4}T_1 \\ &= (10)[(0.3735)(63.3)(1000) + (0.4177)(21.7)(1000) + (0.2088)(0.711)(1000)] - (10)(27.8)(298) \\ &= \mathbf{245,700\text{kJ}} \end{aligned}$$

16-92 Solid carbon is burned with a stoichiometric amount of air. The number of moles of CO_2 formed per mole of carbon is to be determined.

Assumptions 1 The equilibrium composition consists of CO_2 , CO , O_2 , and N_2 . **2** The constituents of the mixture are ideal gases.

Analysis Inspection of Table A-28 reveals that the dissociation equilibrium constants of CO_2 , O_2 , and N_2 are quite small and therefore may be neglected. (We learned from another source that the equilibrium constant for CO is also small). The combustion is then complete and the reaction is described by

The number of moles of CO_2 in the products is then

$$\frac{N_{\text{CO}_2}}{N_{\text{C}}} = 1$$

Carbon + Air
25°C

16-93 Solid carbon is burned with a stoichiometric amount of air. The amount of heat released per kilogram of carbon is to be determined.

Assumptions 1 The equilibrium composition consists of CO_2 , CO , O_2 , and N_2 . **2** The constituents of the mixture are ideal gases.

Analysis Inspection of Table A-28 reveals that the dissociation equilibrium constants of CO_2 , O_2 , and N_2 are quite small and therefore may be neglected. (We learned from another source that the equilibrium constant for CO is also small). The combustion is then complete and the reaction is described by

The heat transfer for this combustion process is determined from the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $W = 0$. It reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{K}}$ kJ/kmol	$\bar{h}_{1000\text{K}}$ kJ/kmol
N_2	0	8669	30,129
CO_2	-393,520	9364	42,769

Substituting,

$$\begin{aligned} -Q_{\text{out}} &= (1)(-393,520 + 42,769 - 9364) + (3.76)(0 + 30,129 - 8669) \\ &= -279,425 \text{ kJ/kmol C} \end{aligned}$$

or
$$Q_{\text{out}} = \frac{279,425 \text{ kJ/kmol}}{12 \text{ kg/kmol}} = \mathbf{23,285 \text{ kJ/kg carbon}}$$

Carbon + Air
25°C

16-94 Methane gas is burned with 30 percent excess air. The equilibrium composition of the products of combustion and the amount of heat released by this combustion are to be determined.

Assumptions 1 The equilibrium composition consists of CO_2 , H_2O , O_2 , NO , and N_2 . **2** The constituents of the mixture are ideal gases.

Analysis Inspection of the equilibrium constants of the possible reactions indicate that only the formation of NO need to be considered in addition to other complete combustion products. Then, the stoichiometric and actual reactions in this case are

Stoichiometric: $\text{N}_2 + \text{O}_2 \Leftrightarrow 2\text{NO}$ (thus $\nu_{\text{N}_2} = 1$, $\nu_{\text{O}_2} = 1$, and $\nu_{\text{NO}} = 2$)

Actual: $\text{CH}_4 + 2.6(\text{O}_2 + 3.76\text{N}_2) \longrightarrow \text{CO}_2 + 2\text{H}_2\text{O} + x\text{NO} + y\text{O}_2 + z\text{N}_2$

N balance: $2 \times 9.776 = x + 2z \longrightarrow z = 9.776 - 0.5x$

O balance: $5.2 = 2 + 2 + x + 2y \longrightarrow y = 0.6 - 0.5x$

Total number of moles: $N_{\text{total}} = 1 + 2 + x + y + z = 13.38$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{\text{NO}}^{\nu_{\text{NO}}}}{N_{\text{N}_2}^{\nu_{\text{N}_2}} N_{\text{O}_2}^{\nu_{\text{O}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{NO}} - \nu_{\text{N}_2} - \nu_{\text{O}_2})}$$

From Table A-28, at 1600 K, $\ln K_p = -5.294$. Since the stoichiometric reaction being considered is double this reaction,

$$K_p = \exp(-2 \times 5.294) = 2.522 \times 10^{-5}$$

Substituting,

$$2.522 \times 10^{-5} = \frac{x^2}{(0.6 - 0.5x)(9.776 - 0.5x)} \left(\frac{1}{13.38} \right)^{2-1-1}$$

Solving for x ,

$$x = 0.0121$$

Then,

$$y = 0.6 - 0.5x = 0.594$$

$$z = 9.776 - 0.5x = 9.77$$

Therefore, the equilibrium composition of the products mixture at 1600 K and 1 atm is

The heat transfer for this combustion process is determined from the energy balance $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ applied on the combustion chamber with $W = 0$. It reduces to

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the air and the combustion products to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{K}}$ kJ/kmol	$\bar{h}_{1600\text{K}}$ kJ/kmol
CH_4	-74,850	---	---
O_2	0	8682	52,961
N_2	0	8669	50,571
H_2O	-241,820	9904	62,748
CO_2	-393,520	9364	76,944

Neglecting the effect of NO in the energy balance and substituting,

$$\begin{aligned} -Q_{\text{out}} &= (1)(-393,520 + 76,944 - 9364) + (2)(-241,820 + 62,748 - 9904) + 0.594(52,961 - 8682) \\ &\quad + (9.77)(50,571 - 8669) - (-74,850) \\ &= -193,500 \text{ kJ/kmol CH}_4 \end{aligned}$$

or $Q_{\text{out}} = 193,500 \text{ kJ/kmol CH}_4$

16-95E Gaseous octane gas is burned with 40% excess air. The equilibrium composition of the products of combustion is to be determined.

Assumptions 1 The equilibrium composition consists of CO_2 , H_2O , O_2 , NO , and N_2 . **2** The constituents of the mixture are ideal gases.

Analysis The stoichiometric and actual reactions in this case are

Stoichiometric: $\text{N}_2 + \text{O}_2 \leftrightarrow 2\text{NO}$ (thus $\nu_{\text{N}_2} = 1$, $\nu_{\text{O}_2} = 1$, and $\nu_{\text{NO}} = 2$)

Actual: $\text{C}_8\text{H}_{18} + 1.4 \times 12.5(\text{O}_2 + 3.76\text{N}_2) \longrightarrow 8\text{CO}_2 + 9\text{H}_2\text{O} + x\text{NO} + y\text{O}_2 + z\text{N}_2$

N balance: $131.6 = x + 2z \longrightarrow z = 65.8 - 0.5x$

O balance: $35 = 16 + 9 + x + 2y \longrightarrow y = 5 - 0.5x$

Total number of moles: $N_{\text{total}} = 8 + 9 + x + y + z = 87.8$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{\text{NO}}^{\nu_{\text{NO}}}}{N_{\text{N}_2}^{\nu_{\text{N}_2}} N_{\text{O}_2}^{\nu_{\text{O}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{NO}} - \nu_{\text{N}_2} - \nu_{\text{O}_2})}$$

From Table A-28, at 2000 K (3600 R), $\ln K_p = -3.931$. Since the stoichiometric reaction being considered is double this reaction,

$$K_p = \exp(-2 \times 3.931) = 3.851 \times 10^{-4}$$

Substituting,

$$3.851 \times 10^{-4} = \frac{x^2}{(5 - 0.5x)(65.8 - 0.5x)} \left(\frac{600/14.7}{87.8} \right)^{2-1-1}$$

Solving for x ,

$$x = 0.3492$$

Then,

$$y = 5 - 0.5x = 4.825$$

$$z = 65.8 - 0.5x = 65.63$$

Therefore, the equilibrium composition of the products mixture at 2000 K and 4 MPa is

16-96 Propane gas is burned with stoichiometric air in an adiabatic manner. The temperature of the products and the equilibrium composition of the products are to be determined.

Assumptions 1 The equilibrium composition consists of CO_2 , H_2O , O_2 , NO , and N_2 . **2** The constituents of the mixture are ideal gases.

Analysis (a) The stoichiometric and actual reactions in this case are

Stoichiometric: $\text{N}_2 + \text{O}_2 \leftrightarrow 2\text{NO}$ (thus $\nu_{\text{N}_2} = 1$, $\nu_{\text{O}_2} = 1$, and $\nu_{\text{NO}} = 2$)

Actual: $\text{C}_3\text{H}_8 + 1.1 \times 5(\text{O}_2 + 3.76\text{N}_2) \longrightarrow 3\text{CO}_2 + 4\text{H}_2\text{O} + x\text{NO} + y\text{O}_2 + z\text{N}_2$

N balance: $41.36 = x + 2z \longrightarrow z = 20.68 - 0.5x$

O balance: $11 = 6 + 4 + x + 2y \longrightarrow y = 0.5 - 0.5x$

Total number of moles: $N_{\text{total}} = 3 + 4 + x + y + z = 21.18$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{\text{NO}}^{\nu_{\text{NO}}}}{N_{\text{N}_2}^{\nu_{\text{N}_2}} N_{\text{O}_2}^{\nu_{\text{O}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{NO}} - \nu_{\text{N}_2} - \nu_{\text{O}_2})}$$

We assume that the products will be at 2000 K. Then from Table A-28, at 2000 K, $\ln K_p = -3.931$. Since the stoichiometric reaction being considered is double this reaction,

$$K_p = \exp(-2 \times 3.931) = 3.851 \times 10^{-4}$$

Substituting,

$$3.851 \times 10^{-4} = \frac{x^2}{(0.5 - 0.5x)(20.68 - 0.5x)} \left(\frac{1}{21.18} \right)^{2-1-1}$$

Solving for x ,

$$x = 0.0611$$

Then,

$$y = 0.5 - 0.5x = 0.4695$$

$$z = 20.68 - 0.5x = 20.65$$

Therefore, the equilibrium composition of the products mixture at 2000 K and 1 atm is

(b) From the tables,

Substance	\bar{h}_f° , kJ/kmol	$\bar{h}_{298\text{K}}$, kJ/kmol
C_3H_8 (g)	-103,850	---
O_2	0	8682
N_2	0	8669
H_2O (g)	-241,820	9904
CO_2	-393,520	9364

Thus,

$$(3)(-393,520 + \bar{h}_{\text{CO}_2} - 9364) + (4)(-241,820 + \bar{h}_{\text{H}_2\text{O}} - 9904) + (0.0611)(39,460 + \bar{h}_{\text{OH}} - 9188) \\ + (0.4695)(0 + \bar{h}_{\text{O}_2} - 8682) + (20.65)(0 + \bar{h}_{\text{N}_2} - 8669) = (1)(-103,850) + 0 + 0$$

It yields

$$3\bar{h}_{\text{CO}_2} + 4\bar{h}_{\text{H}_2\text{O}} + 0.0611\bar{h}_{\text{OH}} + 0.4695\bar{h}_{\text{O}_2} + 20.65\bar{h}_{\text{N}_2} = 2,292,940 \text{ kJ}$$

The adiabatic flame temperature is obtained from a trial and error solution. A first guess is obtained by dividing the right-hand side of the equation by the total number of moles, which yields $2,292,940/(3+4+0.0611+0.4695+20.65) = 81,366$ kJ/kmol. This enthalpy value corresponds to about 2450 K for N_2 . Noting that the majority of the moles are N_2 , T_p will be close to 2450 K, but somewhat under it because of the higher specific heat of H_2O .

At 2200 K:

$$\begin{aligned} 3\bar{h}_{\text{CO}_2} + 4\bar{h}_{\text{H}_2\text{O}} + 0.0611\bar{h}_{\text{OH}} + 0.4695\bar{h}_{\text{O}_2} + 20.65\bar{h}_{\text{N}_2} &= 3(112,939) + 4(92,940) + 0.0611(69,932) \\ &+ 0.4695(75,484) + 20.65(64,810) = 2,088,620 \text{ kJ (Lower than 2,292,940)} \end{aligned}$$

At 2400 K:

$$\begin{aligned} 3\bar{h}_{\text{CO}_2} + 4\bar{h}_{\text{H}_2\text{O}} + 0.0611\bar{h}_{\text{OH}} + 0.4695\bar{h}_{\text{O}_2} + 20.65\bar{h}_{\text{N}_2} &= 3(125,152) + 4(103,508) + 0.0611(77,015) \\ &+ 0.4695(83,174) + 20.65(79,320) = 2,471,200 \text{ kJ (Higher than 2,292,940)} \end{aligned}$$

By interpolation of the two results,

$$T_p = \mathbf{2307 \text{ K} = 2034^\circ\text{C}}$$

16-97 A mixture of H_2 and O_2 in a tank is ignited. The equilibrium composition of the product gases and the amount of heat transfer from the combustion chamber are to be determined.

Assumptions 1 The equilibrium composition consists of H_2O , H_2 , and O_2 . **2** The constituents of the mixture are ideal gases.

Analysis (a) The combustion equation can be written as

The equilibrium equation among H_2O , H_2 , and O_2 can be expressed as

Total number of moles: $N_{\text{total}} = x + (1-x) + (0.5-0.5x) = 1.5-0.5x$

The equilibrium constant relation can be expressed as

$$K_p = \frac{N_{\text{H}_2}^{\nu_{\text{H}_2}} N_{\text{O}_2}^{\nu_{\text{O}_2}}}{N_{\text{H}_2\text{O}}^{\nu_{\text{H}_2\text{O}}}} \left(\frac{P}{N_{\text{total}}} \right)^{(\nu_{\text{H}_2} + \nu_{\text{O}_2} - \nu_{\text{H}_2\text{O}})}$$

From Table A-28, $\ln K_p = -3.812$ at 2800 K. Thus $K_p = 0.02210$. Substituting,

$$0.0221 = \frac{(1-x)(0.5-0.5x)^{0.5}}{x} \left(\frac{5}{1.5-0.5x} \right)^{1+0.5-1}$$

Solving for x , $x = 0.944$

Then the combustion equation and the equilibrium composition can be expressed as

and **$0.944\text{H}_2\text{O} + 0.056\text{H}_2 + 0.028\text{O}_2$**

(b) The heat transfer can be determined from

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ - P\bar{v})_R$$

Since $W = 0$ and both the reactants and the products are assumed to be ideal gases, all the internal energy and enthalpies depend on temperature only, and the $P\bar{v}$ terms in this equation can be replaced by $R_u T$. It yields

$$-Q_{\text{out}} = \sum N_P (\bar{h}_f^\circ + \bar{h}_{2800\text{K}} - \bar{h}_{298\text{K}} - R_u T)_P - \sum N_R (\bar{h}_f^\circ - R_u T)_R$$

since reactants are at the standard reference temperature of 25°C. From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{K}}$ kJ/kmol	$\bar{h}_{2800\text{K}}$ kJ/kmol
H_2	0	8468	89,838
O_2	0	8682	98,826
H_2O	-241,820	9904	125,198

Substituting,

$$\begin{aligned} -Q_{\text{out}} &= 0.944(-241,820 + 125,198 - 9904 - 8.314 \times 2800) \\ &\quad + 0.056(0 + 89,838 - 8468 - 8.314 \times 2800) \\ &\quad + 0.028(0 + 98,826 - 8682 - 8.314 \times 2800) \\ &\quad - 1(0 - 8.314 \times 298) - 0.5(0 - 8.314 \times 298) \\ &= -132,574 \text{ kJ/kmol H}_2 \end{aligned}$$

or $Q_{\text{out}} = 132,574 \text{ kJ/mol H}_2$

The equilibrium constant for the reaction $\text{H}_2\text{O} \Leftrightarrow \text{OH} + \frac{1}{2}\text{H}_2$ is $\ln K_p = -3.763$, which is very close to the K_p value of the reaction considered. Therefore, it is not realistic to assume that no OH will be present in equilibrium mixture.

H_2O , H_2 , O_2
2800 K
5 atm

16-98 A mixture of H_2O and O_2 is heated to a high temperature. The equilibrium composition is to be determined.

Assumptions 1 The equilibrium composition consists of H_2O , OH , O_2 , and H_2 . **2** The constituents of the mixture are ideal gases.

Analysis The reaction equation during this process can be expressed as

H_2O , OH , H_2 , O_2
3600 K
8 atm

Mass balances for hydrogen and oxygen yield

$$\text{H balance:} \quad 4 = 2x + 2y + w \quad (1)$$

$$\text{O balance:} \quad 8 = x + 2z + w \quad (2)$$

The mass balances provide us with only two equations with four unknowns, and thus we need to have two more equations (to be obtained from the K_P relations) to determine the equilibrium composition of the mixture. They are

The equilibrium constant for these two reactions at 3600 K are determined from Table A-28 to be

$$\ln K_{P1} = -1.392 \longrightarrow K_{P1} = 0.24858$$

$$\ln K_{P2} = -1.088 \longrightarrow K_{P2} = 0.33689$$

The K_P relations for these two simultaneous reactions are

$$K_{P1} = \frac{N_{\text{H}_2}^{v_{\text{H}_2}} N_{\text{O}_2}^{v_{\text{O}_2}}}{N_{\text{H}_2\text{O}}^{v_{\text{H}_2\text{O}}}} \left(\frac{P}{N_{\text{total}}} \right)^{(v_{\text{H}_2} + v_{\text{O}_2} - v_{\text{H}_2\text{O}})}$$

$$K_{P2} = \frac{N_{\text{H}_2}^{v_{\text{H}_2}} N_{\text{OH}}^{v_{\text{OH}}}}{N_{\text{H}_2\text{O}}^{v_{\text{H}_2\text{O}}}} \left(\frac{P}{N_{\text{total}}} \right)^{(v_{\text{H}_2} + v_{\text{OH}} - v_{\text{H}_2\text{O}})}$$

where

$$N_{\text{total}} = N_{\text{H}_2\text{O}} + N_{\text{H}_2} + N_{\text{O}_2} + N_{\text{OH}} = x + y + z + w$$

Substituting,

$$0.24858 = \frac{(y)(z)^{1/2}}{x} \left(\frac{8}{x + y + z + w} \right)^{1/2} \quad (3)$$

$$0.33689 = \frac{(w)(y)^{1/2}}{x} \left(\frac{8}{x + y + z + w} \right)^{1/2} \quad (4)$$

Solving Eqs. (1), (2), (3), and (4) simultaneously for the four unknowns x , y , z , and w yields

$$x = 1.371 \quad y = 0.1646 \quad z = 2.85 \quad w = 0.928$$

Therefore, the equilibrium composition becomes

16-99 A mixture of CO_2 and O_2 is heated to a high temperature. The equilibrium composition is to be determined.

Assumptions 1 The equilibrium composition consists of CO_2 , CO , O_2 , and O . **2** The constituents of the mixture are ideal gases.

Analysis The reaction equation during this process can be expressed as

Mass balances for carbon and oxygen yield

$$\text{C balance:} \quad 3 = x + y \quad (1)$$

$$\text{O balance:} \quad 12 = 2x + y + 2z + w \quad (2)$$

$\text{CO}_2, \text{CO}, \text{O}_2, \text{O}$
3400 K
2 atm

The mass balances provide us with only two equations with four unknowns, and thus we need to have two more equations (to be obtained from the K_p relations) to determine the equilibrium composition of the mixture. They are

The equilibrium constant for these two reactions at 3400 K are determined from Table A-28 to be

$$\ln K_{p1} = 0.169 \longrightarrow K_{p1} = 1.184$$

$$\ln K_{p2} = -1.935 \longrightarrow K_{p2} = 0.1444$$

The K_p relations for these two simultaneous reactions are

$$K_{p1} = \frac{N_{\text{CO}}^{v_{\text{CO}}} N_{\text{O}_2}^{v_{\text{O}_2}}}{N_{\text{CO}_2}^{v_{\text{CO}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{(v_{\text{CO}} + v_{\text{O}_2} - v_{\text{CO}_2})}$$

$$K_{p2} = \frac{N_{\text{O}}^{v_{\text{O}}}}{N_{\text{O}_2}^{v_{\text{O}_2}}} \left(\frac{P}{N_{\text{total}}} \right)^{v_{\text{O}} - v_{\text{O}_2}}$$

where

$$N_{\text{total}} = N_{\text{CO}_2} + N_{\text{O}_2} + N_{\text{CO}} + N_{\text{O}} = x + y + z + w$$

Substituting,

$$1.184 = \frac{(y)(z)^{1/2}}{x} \left(\frac{2}{x + y + z + w} \right)^{1/2} \quad (3)$$

$$0.1444 = \frac{w^2}{z} \left(\frac{2}{x + y + z + w} \right)^{2-1} \quad (4)$$

Solving Eqs. (1), (2), (3), and (4) simultaneously for the four unknowns x , y , z , and w yields

$$x = 1.313 \quad y = 1.687 \quad z = 3.187 \quad w = 1.314$$

Thus the equilibrium composition is

16-100 Problem 16-99 is reconsidered. The effect of pressure on the equilibrium composition by varying pressure from 1 atm to 10 atm is to be studied.

Analysis The problem is solved using EES, and the solution is given below.

16-101 The \bar{h}_R at a specified temperature is to be determined using enthalpy and K_p data.

Assumptions Both the reactants and products are ideal gases.

Analysis (a) The complete combustion equation of H_2 can be expressed as

The \bar{h}_R of the combustion process of H_2 at 2400 K is the amount of energy released as one kmol of H_2 is burned in a steady-flow combustion chamber at a temperature of 2400 K, and can be determined from

$$\bar{h}_R = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the H_2O , H_2 , and O_2 to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{ K}}$ kJ/kmol	$\bar{h}_{2400\text{ K}}$ kJ/kmol
H_2O	-241,820	9904	103,508
H_2	0	8468	75,383
O_2	0	8682	83,174

Substituting,

$$\begin{aligned} \bar{h}_R &= 1(-241,820 + 103,508 - 9904) \\ &\quad - 1(0 + 75,383 - 8468) \\ &\quad - 0.5(0 + 83,174 - 8682) \\ &= \mathbf{-252,377\text{ kJ/kmol}} \end{aligned}$$

(b) The \bar{h}_R value at 2400 K can be estimated by using K_p values at 2200 K and 2600 K (the closest two temperatures to 2400 K for which K_p data are available) from Table A-28,

$$\begin{aligned} \ln \frac{K_{P2}}{K_{P1}} &\cong \frac{\bar{h}_R}{R_u} \left(\frac{1}{T_1} - \frac{1}{T_2} \right) \quad \text{or} \quad \ln K_{P2} - \ln K_{P1} \cong \frac{\bar{h}_R}{R_u} \left(\frac{1}{T_1} - \frac{1}{T_2} \right) \\ 4.648 - 6.768 &\cong \frac{\bar{h}_R}{8.314\text{ kJ/kmol}\cdot\text{K}} \left(\frac{1}{2200\text{ K}} - \frac{1}{2600\text{ K}} \right) \\ \bar{h}_R &\cong \mathbf{-252,047\text{ kJ/kmol}} \end{aligned}$$

16-102 Problem 16-101 is reconsidered. The effect of temperature on the enthalpy of reaction using both methods by varying the temperature from 2000 to 3000 K is to be investigated.

Analysis The problem is solved using EES, and the solution is given below.

16-103 The K_p value of the dissociation process $O_2 \leftrightarrow 2O$ at a specified temperature is to be determined using the \bar{h}_R data and K_p value at a specified temperature.

Assumptions Both the reactants and products are ideal gases.

Analysis The \bar{h}_R and K_p data are related to each other by

$$\ln \frac{K_{p2}}{K_{p1}} \cong \frac{\bar{h}_R}{R_u} \left(\frac{1}{T_1} - \frac{1}{T_2} \right) \quad \text{or} \quad \ln K_{p2} - \ln K_{p1} \cong \frac{\bar{h}_R}{R_u} \left(\frac{1}{T_1} - \frac{1}{T_2} \right)$$

The \bar{h}_R of the specified reaction at 2200 K is the amount of energy released as one kmol of O_2 dissociates in a steady-flow combustion chamber at a temperature of 2200 K, and can be determined from

$$\bar{h}_R = \sum N_P (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_P - \sum N_R (\bar{h}_f^\circ + \bar{h} - \bar{h}^\circ)_R$$

Assuming the O_2 and O to be ideal gases, we have $h = h(T)$. From the tables,

Substance	\bar{h}_f° kJ/kmol	$\bar{h}_{298\text{ K}}$ kJ/kmol	$\bar{h}_{2200\text{ K}}$ kJ/kmol
O	249,190	6852	46,728
O_2	0	8682	75,484

Substituting,

$$\bar{h}_R = 2(249,190 + 46,728 - 6852) - 1(0 + 75,484 - 8682) = 511,330 \text{ kJ/kmol}$$

The K_p value at 2400 K can be estimated from the equation above by using this \bar{h}_R value and the K_p value at 2000 K which is $\ln K_{p1} = -14.622$,

$$\ln K_{p2} - (-14.622) = \frac{511,330 \text{ kJ/kmol}}{8.314 \text{ kJ/kmol} \cdot \text{K}} \left(\frac{1}{2000 \text{ K}} - \frac{1}{2400 \text{ K}} \right)$$

$$\ln K_{p2} = -9.497 \quad (\text{Table A - 28: } \ln K_{p2} = -9.497)$$

or

$$K_{p2} = 7.51 \times 10^{-5}$$

16-104 A 2-L bottle is filled with carbonated drink that is fully charged (saturated) with CO₂ gas. The volume that the CO₂ gas would occupy if it is released and stored in a container at room conditions is to be determined.

Assumptions 1 The liquid drink can be treated as water. **2** Both the CO₂ gas and the water vapor are ideal gases. **3** The CO₂ gas is weakly soluble in water and thus Henry's law is applicable.

Properties The saturation pressure of water at 17°C is 1.938 kPa (Table A-4). Henry's constant for CO₂ dissolved in water at 17°C (290 K) is $H = 1280$ bar (Table 16-2). Molar masses of CO₂ and water are 44.01 and 18.015 kg/kmol, respectively (Table A-1). The gas constant of CO₂ is 0.1889 kPa·m³/kg·K. Also, 1 bar = 100 kPa.

Analysis In the charging station, the CO₂ gas and water vapor mixture above the liquid will form a saturated mixture. Noting that the saturation pressure of water at 17°C is 1.938 kPa, the partial pressure of the CO₂ gas is

$$P_{\text{CO}_2, \text{gas side}} = P - P_{\text{vapor}} = P - P_{\text{sat @ 17°C}} = 600 - 1.938 = 598.06 \text{ kPa} = 5.9806 \text{ bar}$$

From Henry's law, the mole fraction of CO₂ in the liquid drink is determined to be

$$y_{\text{CO}_2, \text{liquid side}} = \frac{P_{\text{CO}_2, \text{gas side}}}{H} = \frac{5.9806 \text{ bar}}{1280 \text{ bar}} = 0.00467$$

Then the mole fraction of water in the drink becomes

$$y_{\text{water, liquid side}} = 1 - y_{\text{CO}_2, \text{liquid side}} = 1 - 0.00467 = 0.99533$$

The mass and mole fractions of a mixture are related to each other by

$$w_i = \frac{m_i}{m_m} = \frac{N_i M_i}{N_m M_m} = y_i \frac{M_i}{M_m}$$

where the apparent molar mass of the drink (liquid water - CO₂ mixture) is

$$\begin{aligned} M_m &= \sum y_i M_i = y_{\text{liquid water}} M_{\text{water}} + y_{\text{CO}_2} M_{\text{CO}_2} \\ &= 0.99533 \times 18.015 + 0.00467 \times 44.01 = 18.14 \text{ kg/kmol} \end{aligned}$$

Then the mass fraction of dissolved CO₂ in liquid drink becomes

$$w_{\text{CO}_2, \text{liquid side}} = y_{\text{CO}_2, \text{liquid side}} \frac{M_{\text{CO}_2}}{M_m} = 0.00467 \frac{44.01}{18.14} = 0.0113$$

Therefore, the mass of dissolved CO₂ in a 2 L ≈ 2 kg drink is

$$m_{\text{CO}_2} = w_{\text{CO}_2} m_m = 0.0113(2 \text{ kg}) = 0.0226 \text{ kg}$$

Then the volume occupied by this CO₂ at the room conditions of 20°C and 100 kPa becomes

$$v = \frac{mRT}{P} = \frac{(0.0226 \text{ kg})(0.1889 \text{ kPa} \cdot \text{m}^3 / \text{kg} \cdot \text{K})(293 \text{ K})}{100 \text{ kPa}} = \mathbf{0.0125 \text{ m}^3 = 12.5 \text{ L}}$$

Discussion Note that the amount of dissolved CO₂ in a 2-L pressurized drink is large enough to fill 6 such bottles at room temperature and pressure. Also, we could simplify the calculations by assuming the molar mass of carbonated drink to be the same as that of water, and take it to be 18 kg/kmol because of the very low mole fraction of CO₂ in the drink.

16-105 The natural log of the equilibrium constant as a function of temperature between 298 to 3000 K for the equilibrium reaction $\text{CO} + \text{H}_2\text{O} = \text{CO}_2 + \text{H}_2$ is to be tabulated and compared to those given in Table A-28

Analysis The K_p value of a reaction at a specified temperature can be determined from the Gibbs function data using

$$K_p = e^{-\Delta G^*(T)/R_u T} \quad \text{or} \quad \ln K_p = -\Delta G^*(T) / R_u T$$

where

$$\Delta G^*(T) = \nu_{\text{CO}_2} \bar{g}_{\text{CO}_2}^*(T) + \nu_{\text{H}_2} \bar{g}_{\text{H}_2}^*(T) - \nu_{\text{CO}} \bar{g}_{\text{CO}}^*(T) - \nu_{\text{H}_2\text{O}} \bar{g}_{\text{H}_2\text{O}}^*(T)$$

and the Gibbs functions are defined as

$$\bar{g}_{\text{CO}}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}} \bar{s})_{\text{CO}}$$

$$\bar{g}_{\text{H}_2\text{O}}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}} \bar{s})_{\text{H}_2\text{O}}$$

$$\bar{g}_{\text{CO}_2}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}} \bar{s})_{\text{CO}_2}$$

$$\bar{g}_{\text{H}_2}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}} \bar{s})_{\text{H}_2}$$

The copy of entire EES solution with resulting parametric table is given next:

16-106 Ethyl alcohol C_2H_5OH (gas) is burned in a steady-flow adiabatic combustion chamber with 90 percent excess air. The adiabatic flame temperature of the products is to be determined and the adiabatic flame temperature as a function of the percent excess air is to be plotted.

Analysis The complete combustion reaction in this case can be written as

where a_{th} is the stoichiometric coefficient for air. The oxygen balance gives

$$1 + (1 + Ex)a_{\text{th}} \times 2 = 2 \times 2 + 3 \times 1 + (Ex)(a_{\text{th}}) \times 2$$

The reaction equation with products in equilibrium is

The coefficients are determined from the mass balances

Carbon balance: $2 = a + b$

Hydrogen balance: $6 = 2d \longrightarrow d = 3$

Oxygen balance: $1 + (1 + Ex)a_{\text{th}} \times 2 = a \times 2 + b + d + e \times 2$

Nitrogen balance: $(1 + Ex)a_{\text{th}} \times 3.76 = f$

Solving the above equations, we find the coefficients to be

$$Ex = 0.9, a_{\text{th}} = 3, a = 2, b = 0.00008644, d = 3, e = 2.7, f = 21.43$$

Then, we write the balanced reaction equation as

Total moles of products at equilibrium are

$$N_{\text{tot}} = 2 + 0.00008644 + 3 + 2.7 + 21.43 = 29.13$$

The assumed equilibrium reaction is

The K_p value of a reaction at a specified temperature can be determined from the Gibbs function data using

$$K_p = e^{-\Delta G^*(T)/R_u T} \quad \text{or} \quad \ln K_p = -\Delta G^*(T) / R_u T$$

where

$$\Delta G^*(T) = \nu_{CO} \bar{g}_{CO}^*(T_{\text{prod}}) + \nu_{O_2} \bar{g}_{O_2}^*(T_{\text{prod}}) - \nu_{CO_2} \bar{g}_{CO_2}^*(T_{\text{prod}})$$

and the Gibbs functions are defined as

$$\bar{g}_{CO}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}} \bar{s})_{CO}$$

$$\bar{g}_{O_2}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}} \bar{s})_{O_2}$$

$$\bar{g}_{CO_2}^*(T_{\text{prod}}) = (\bar{h} - T_{\text{prod}} \bar{s})_{CO_2}$$

The equilibrium constant is also given by

$$K_p = \frac{be^{0.5}}{a} \left(\frac{P}{N_{\text{tot}}} \right)^{1+0.5-1} = \frac{(0.00008644)(2.7)^{0.5}}{2} \left(\frac{1}{29.13} \right)^{0.5} = 0.00001316$$

A steady flow energy balance gives

$$H_R = H_P$$

where

$$H_R = \bar{h}_{f_{\text{fuel}@25^\circ\text{C}}}^o + 5.7\bar{h}_{\text{O}_2@25^\circ\text{C}} + 21.43\bar{h}_{\text{N}_2@25^\circ\text{C}}$$

$$= (-235,310 \text{ kJ/kmol}) + 5.7(0) + 21.43(0) = -235,310 \text{ kJ/kmol}$$

$$H_P = 2\bar{h}_{\text{CO}_2@T_{\text{prod}}} + 0.00008644\bar{h}_{\text{CO}@T_{\text{prod}}} + 3h_{\text{H}_2\text{O}@T_{\text{prod}}} + 2.7\bar{h}_{\text{O}_2@T_{\text{prod}}} + 21.43\bar{h}_{\text{N}_2@T_{\text{prod}}}$$

Solving the energy balance equation using EES, we obtain the adiabatic flame temperature to be

$$T_{\text{prod}} = \mathbf{1569\text{K}}$$

16-107 It is to be shown that when the three phases of a pure substance are in equilibrium, the specific Gibbs function of each phase is the same.

Analysis The total Gibbs function of the three phase mixture of a pure substance can be expressed as

$$G = m_s g_s + m_\ell g_\ell + m_g g_g$$

where the subscripts s , ℓ , and g indicate solid, liquid and gaseous phases. Differentiating by holding the temperature and pressure (thus the Gibbs functions, g) constant yields

$$dG = g_s dm_s + g_\ell dm_\ell + g_g dm_g$$

From conservation of mass,

$$dm_s + dm_\ell + dm_g = 0 \quad \longrightarrow \quad dm_s = -dm_\ell - dm_g$$

Substituting,

$$dG = -g_s(dm_\ell + dm_g) + g_\ell dm_\ell + g_g dm_g$$

Rearranging,

$$dG = (g_\ell - g_s)dm_\ell + (g_g - g_s)dm_g$$

For equilibrium, $dG = 0$. Also dm_ℓ and dm_g can be varied independently. Thus each term on the right hand side must be zero to satisfy the equilibrium criteria. It yields

$$g_\ell = g_s \quad \text{and} \quad g_g = g_s$$

Combining these two conditions gives the desired result,

$$g_\ell = g_s = g_g$$

16-108 It is to be shown that when the two phases of a two-component system are in equilibrium, the specific Gibbs function of each phase of each component is the same.

Analysis The total Gibbs function of the two phase mixture can be expressed as

$$G = (m_{\ell 1} g_{\ell 1} + m_{g 1} g_{g 1}) + (m_{\ell 2} g_{\ell 2} + m_{g 2} g_{g 2})$$

where the subscripts ℓ and g indicate liquid and gaseous phases. Differentiating by holding the temperature and pressure (thus the Gibbs functions) constant yields

$$dG = g_{\ell 1} dm_{\ell 1} + g_{g 1} dm_{g 1} + g_{\ell 2} dm_{\ell 2} + g_{g 2} dm_{g 2}$$

From conservation of mass,

$$dm_{g 1} = -dm_{\ell 1} \quad \text{and} \quad dm_{g 2} = -dm_{\ell 2}$$

Substituting,

$$dG = (g_{\ell 1} - g_{g 1})dm_{\ell 1} + (g_{\ell 2} - g_{g 2})dm_{\ell 2}$$

For equilibrium, $dG = 0$. Also $dm_{\ell 1}$ and $dm_{\ell 2}$ can be varied independently. Thus each term on the right hand side must be zero to satisfy the equilibrium criteria. Then we have

$$g_{\ell 1} = g_{g 1} \quad \text{and} \quad g_{\ell 2} = g_{g 2}$$

which is the desired result.

Fundamentals of Engineering (FE) Exam Problems

16-109 If the equilibrium constant for the reaction $\text{H}_2 + \frac{1}{2}\text{O}_2 \rightarrow \text{H}_2\text{O}$ is K , the equilibrium constant for the reaction $2\text{H}_2\text{O} \rightarrow 2\text{H}_2 + \text{O}_2$ at the same temperature is

- (a) $1/K$ (b) $1/(2K)$ (c) $2K$ (d) K^2 (e) $1/K^2$

Answer (e) $1/K^2$

16-110 If the equilibrium constant for the reaction $\text{CO} + \frac{1}{2}\text{O}_2 \rightarrow \text{CO}_2$ is K , the equilibrium constant for the reaction $\text{CO}_2 + 3\text{N}_2 \rightarrow \text{CO} + \frac{1}{2}\text{O}_2 + 3\text{N}_2$ at the same temperature is

- (a) $1/K$ (b) $1/(K + 3)$ (c) $4K$ (d) K (e) $1/K^2$

Answer (a) $1/K$

16-111 The equilibrium constant for the reaction $\text{H}_2 + \frac{1}{2}\text{O}_2 \rightarrow \text{H}_2\text{O}$ at 1 atm and 1500°C is given to be K . Of the reactions given below, all at 1500°C , the reaction that has a different equilibrium constant is

- (a) $\text{H}_2 + \frac{1}{2}\text{O}_2 \rightarrow \text{H}_2\text{O}$ at 5 atm,
 (b) $2\text{H}_2 + \text{O}_2 \rightarrow 2\text{H}_2\text{O}$ at 1 atm,
 (c) $\text{H}_2 + \text{O}_2 \rightarrow \text{H}_2\text{O} + \frac{1}{2}\text{O}_2$ at 2 atm,
 (d) $\text{H}_2 + \frac{1}{2}\text{O}_2 + 3\text{N}_2 \rightarrow \text{H}_2\text{O} + 3\text{N}_2$ at 5 atm,
 (e) $\text{H}_2 + \frac{1}{2}\text{O}_2 + 3\text{N}_2 \rightarrow \text{H}_2\text{O} + 3\text{N}_2$ at 1 atm,

Answer (b) $2\text{H}_2 + \text{O}_2 \rightarrow 2\text{H}_2\text{O}$ at 1 atm,

16-112 Of the reactions given below, the reaction whose equilibrium composition at a specified temperature is not affected by pressure is

- (a) $\text{H}_2 + \frac{1}{2}\text{O}_2 \rightarrow \text{H}_2\text{O}$
 (b) $\text{CO} + \frac{1}{2}\text{O}_2 \rightarrow \text{CO}_2$
 (c) $\text{N}_2 + \text{O}_2 \rightarrow 2\text{NO}$
 (d) $\text{N}_2 \rightarrow 2\text{N}$
 (e) all of the above.

Answer (c) $\text{N}_2 + \text{O}_2 \rightarrow 2\text{NO}$

16-113 Of the reactions given below, the reaction whose number of moles of products increases by the addition of inert gases into the reaction chamber at constant pressure and temperature is

- (a) $\text{H}_2 + \frac{1}{2}\text{O}_2 \rightarrow \text{H}_2\text{O}$
- (b) $\text{CO} + \frac{1}{2}\text{O}_2 \rightarrow \text{CO}_2$
- (c) $\text{N}_2 + \text{O}_2 \rightarrow 2\text{NO}$
- (d) $\text{N}_2 \rightarrow 2\text{N}$
- (e) none of the above.

Answer (d) $\text{N}_2 \rightarrow 2\text{N}$

16-114 Moist air is heated to a very high temperature. If the equilibrium composition consists of H_2O , O_2 , N_2 , OH , H_2 , and NO , the number of equilibrium constant relations needed to determine the equilibrium composition of the mixture is

- (a) 1
- (b) 2
- (c) 3
- (d) 4
- (e) 5

Answer (c) 3

16-115 Propane C_3H_8 is burned with air, and the combustion products consist of CO_2 , CO , H_2O , O_2 , N_2 , OH , H_2 , and NO . The number of equilibrium constant relations needed to determine the equilibrium composition of the mixture is

- (a) 1
- (b) 2
- (c) 3
- (d) 4
- (e) 5

Answer (d) 4

16-116 Consider a gas mixture that consists of three components. The number of independent variables that need to be specified to fix the state of the mixture is

- (a) 1
- (b) 2
- (c) 3
- (d) 4
- (e) 5

Answer (d) 4

16-117 The value of Henry's constant for CO₂ gas dissolved in water at 290 K is 12.8 MPa. Consider water exposed to air at 100 kPa that contains 3 percent CO₂ by volume. Under phase equilibrium conditions, the mole fraction of CO₂ gas dissolved in water at 290 K is

- (a) 2.3×10^{-4} (b) 3.0×10^{-4} (c) 0.80×10^{-4} (d) 2.2×10^{-4} (e) 5.6×10^{-4}

Answer (a) 2.3×10^{-4}

Stagnation Properties

17-1C We are to discuss the temperature change from an airplane's nose to far away from the aircraft.

Analysis The temperature of the air **rises as it approaches the nose because of the stagnation process.**

Discussion In the frame of reference moving with the aircraft, the air decelerates from high speed to zero at the nose (stagnation point), and this causes the air temperature to rise.

17-2C We are to define dynamic temperature.

Analysis *Dynamic temperature is the temperature rise of a fluid during a stagnation process.*

Discussion When a gas decelerates from high speed to zero speed at a stagnation point, the temperature of the gas rises.

17-3C We are to discuss the measurement of flowing air temperature with a probe – is there significant error?

Analysis **No, there is not significant error**, because the velocities encountered in air-conditioning applications are very low, and thus the static and the stagnation temperatures are practically identical.

Discussion If the air stream were supersonic, however, the error would indeed be significant.

17-4 Air flows through a device. The stagnation temperature and pressure of air and its velocity are specified. The static pressure and temperature of air are to be determined.

Assumptions **1** The stagnation process is isentropic. **2** Air is an ideal gas.

Properties The properties of air at an anticipated average temperature of 600 K are $c_p = 1.051 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.376$.

Analysis The static temperature and pressure of air are determined from

$$T = T_0 - \frac{V^2}{2c_p} = 673.2 - \frac{(570 \text{ m/s})^2}{2 \times 1.051 \text{ kJ/kg} \cdot \text{K}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 518.6 \text{ K} \cong \mathbf{519 \text{ K}}$$

and

$$P_2 = P_{02} \left(\frac{T_2}{T_{02}} \right)^{k/(k-1)} = (0.6 \text{ MPa}) \left(\frac{518.6 \text{ K}}{673.2 \text{ K}} \right)^{1.376/(1.376-1)} = \mathbf{0.231 \text{ MPa}}$$

Discussion Note that the stagnation properties can be significantly different than thermodynamic properties.

17-5 Air at 320 K is flowing in a duct. The temperature that a stationary probe inserted into the duct will read is to be determined for different air velocities.

Assumptions The stagnation process is isentropic.

Properties The specific heat of air at room temperature is $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$.

Analysis The air which strikes the probe will be brought to a complete stop, and thus it will undergo a stagnation process. The thermometer will sense the temperature of this stagnated air, which is the stagnation temperature, T_0 . It is

determined from $T_0 = T + \frac{V^2}{2c_p}$. The results for each case are calculated below:

$$(a) \quad T_0 = 320 \text{ K} + \frac{(1 \text{ m/s})^2}{2 \times 1.005 \text{ kJ/kg}\cdot\text{K}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = \mathbf{320.0K}$$

$$(b) \quad T_0 = 320 \text{ K} + \frac{(10 \text{ m/s})^2}{2 \times 1.005 \text{ kJ/kg}\cdot\text{K}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = \mathbf{320.1K}$$

$$(c) \quad T_0 = 320 \text{ K} + \frac{(100 \text{ m/s})^2}{2 \times 1.005 \text{ kJ/kg}\cdot\text{K}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = \mathbf{325.0K}$$

$$(d) \quad T_0 = 320 \text{ K} + \frac{(1000 \text{ m/s})^2}{2 \times 1.005 \text{ kJ/kg}\cdot\text{K}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = \mathbf{817.5K}$$

Discussion Note that the stagnation temperature is nearly identical to the thermodynamic temperature at low velocities, but the difference between the two is significant at high velocities.

17-6 The states of different substances and their velocities are specified. The stagnation temperature and stagnation pressures are to be determined.

Assumptions 1 The stagnation process is isentropic. 2 Helium and nitrogen are ideal gases.

Analysis (a) Helium can be treated as an ideal gas with $c_p = 5.1926 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.667$. Then the stagnation temperature and pressure of helium are determined from

$$T_0 = T + \frac{V^2}{2c_p} = 50^\circ\text{C} + \frac{(240 \text{ m/s})^2}{2 \times 5.1926 \text{ kJ/kg}\cdot^\circ\text{C}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = \mathbf{55.5^\circ\text{C}}$$

$$P_0 = P \left(\frac{T_0}{T} \right)^{k/(k-1)} = (0.25 \text{ MPa}) \left(\frac{328.7 \text{ K}}{323.2 \text{ K}} \right)^{1.667/(1.667-1)} = \mathbf{0.261 \text{ MPa}}$$

(b) Nitrogen can be treated as an ideal gas with $c_p = 1.039 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.400$. Then the stagnation temperature and pressure of nitrogen are determined from

$$T_0 = T + \frac{V^2}{2c_p} = 50^\circ\text{C} + \frac{(300 \text{ m/s})^2}{2 \times 1.039 \text{ kJ/kg}\cdot^\circ\text{C}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = \mathbf{93.3^\circ\text{C}}$$

$$P_0 = P \left(\frac{T_0}{T} \right)^{k/(k-1)} = (0.15 \text{ MPa}) \left(\frac{366.5 \text{ K}}{323.2 \text{ K}} \right)^{1.4/(1.4-1)} = \mathbf{0.233 \text{ MPa}}$$

(c) Steam can be treated as an ideal gas with $c_p = 1.865 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.329$. Then the stagnation temperature and pressure of steam are determined from

$$T_0 = T + \frac{V^2}{2c_p} = 350^\circ\text{C} + \frac{(480 \text{ m/s})^2}{2 \times 1.865 \text{ kJ/kg}\cdot^\circ\text{C}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = \mathbf{411.8^\circ\text{C} = 685 \text{ K}}$$

$$P_0 = P \left(\frac{T_0}{T} \right)^{k/(k-1)} = (0.1 \text{ MPa}) \left(\frac{685 \text{ K}}{623.2 \text{ K}} \right)^{1.329/(1.329-1)} = \mathbf{0.147 \text{ MPa}}$$

Discussion Note that the stagnation properties can be significantly different than thermodynamic properties.

17-7 The state of air and its velocity are specified. The stagnation temperature and stagnation pressure of air are to be determined.

Assumptions 1 The stagnation process is isentropic. 2 Air is an ideal gas.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$.

Analysis The stagnation temperature of air is determined from

$$T_0 = T + \frac{V^2}{2c_p} = 238 \text{ K} + \frac{(325 \text{ m/s})^2}{2 \times 1.005 \text{ kJ/kg}\cdot\text{K}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 290.5 \cong \mathbf{291 \text{ K}}$$

Other stagnation properties at the specified state are determined by considering an isentropic process between the specified state and the stagnation state,

$$P_0 = P \left(\frac{T_0}{T} \right)^{k/(k-1)} = (36 \text{ kPa}) \left(\frac{290.5 \text{ K}}{238 \text{ K}} \right)^{1.4/(1.4-1)} = 72.37 \text{ kPa} \cong \mathbf{72.4 \text{ kPa}}$$

Discussion Note that the stagnation properties can be significantly different than thermodynamic properties.

17-8E Steam flows through a device. The stagnation temperature and pressure of steam and its velocity are specified. The static pressure and temperature of the steam are to be determined.

Assumptions 1 The stagnation process is isentropic. 2 Steam is an ideal gas.

Properties Steam can be treated as an ideal gas with $c_p = 0.4455 \text{ Btu/lbm}\cdot\text{R}$ and $k = 1.329$.

Analysis The static temperature and pressure of steam are determined from

$$T = T_0 - \frac{V^2}{2c_p} = 700^\circ\text{F} - \frac{(900 \text{ ft/s})^2}{2 \times 0.4455 \text{ Btu/lbm}\cdot^\circ\text{F}} \left(\frac{1 \text{ Btu/lbm}}{25,037 \text{ ft}^2/\text{s}^2} \right) = \mathbf{663.7^\circ\text{F}}$$

$$P = P_0 \left(\frac{T}{T_0} \right)^{k/(k-1)} = (120 \text{ psia}) \left(\frac{1123.7 \text{ R}}{1160 \text{ R}} \right)^{1.329/(1.329-1)} = \mathbf{105.5 \text{ psia}}$$

Discussion Note that the stagnation properties can be significantly different than thermodynamic properties.

17-9 The inlet stagnation temperature and pressure and the exit stagnation pressure of air flowing through a compressor are specified. The power input to the compressor is to be determined.

Assumptions 1 The compressor is isentropic. 2 Air is an ideal gas.

Properties The properties of air at room temperature are $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$.

Analysis The exit stagnation temperature of air T_{02} is determined from

$$T_{02} = T_{01} \left(\frac{P_{02}}{P_{01}} \right)^{(k-1)/k} = (308.2 \text{ K}) \left(\frac{900}{100} \right)^{(1.4-1)/1.4} = 577.4 \text{ K}$$

From the energy balance on the compressor,

$$\dot{W}_{\text{in}} = \dot{m}(h_{20} - h_{01})$$

or,

$$\dot{W}_{\text{in}} = \dot{m}c_p(T_{02} - T_{01}) = (0.04 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(577.4 - 308.2)\text{K} = \mathbf{10.8 \text{ kW}}$$

Discussion Note that the stagnation properties can be used conveniently in the energy equation.

17-10 The inlet stagnation temperature and pressure and the exit stagnation pressure of products of combustion flowing through a gas turbine are specified. The power output of the turbine is to be determined.

Assumptions 1 The expansion process is isentropic. 2 Products of combustion are ideal gases.

Properties The properties of products of combustion are $c_p = 1.157 \text{ kJ/kg}\cdot\text{K}$, $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.33$.

Analysis The exit stagnation temperature T_{02} is determined to be

$$T_{02} = T_{01} \left(\frac{P_{02}}{P_{01}} \right)^{(k-1)/k} = (963.2 \text{ K}) \left(\frac{0.1}{0.75} \right)^{(1.33-1)/1.33} = 584.2 \text{ K}$$

Also,

$$\begin{aligned} c_p = kc_v = k(c_p - R) &\longrightarrow c_p = \frac{kR}{k-1} \\ &= \frac{1.33(0.287 \text{ kJ/kg}\cdot\text{K})}{1.33-1} \\ &= 1.157 \text{ kJ/kg}\cdot\text{K} \end{aligned}$$

From the energy balance on the turbine,

$$-w_{\text{out}} = (h_{20} - h_{01})$$

$$\text{or, } w_{\text{out}} = c_p(T_{01} - T_{02}) = (1.157 \text{ kJ/kg}\cdot\text{K})(963.2 - 584.2)\text{K} = 438.5 \text{ kJ/kg} \cong \mathbf{439 \text{ kJ/kg}}$$

Discussion Note that the stagnation properties can be used conveniently in the energy equation.

Speed of Sound and Mach Number

17-11C We are to define and discuss sound and how it is generated and how it travels.

Analysis *Sound is an infinitesimally small pressure wave. It is generated by a small disturbance in a medium. It travels by wave propagation. Sound waves cannot travel in a vacuum.*

Discussion Electromagnetic waves, like light and radio waves, can travel in a vacuum, but sound cannot.

17-12C We are to discuss whether sound travels faster in warm or cool air.

Analysis Sound travels faster in **warm (higher temperature) air** since $c = \sqrt{kRT}$.

Discussion On the microscopic scale, we can imagine the air molecules moving around at higher speed in warmer air, leading to higher propagation of disturbances.

17-13C We are to compare the speed of sound in air, helium, and argon.

Analysis **Sound travels fastest in helium**, since $c = \sqrt{kRT}$ and helium has the highest kR value. It is about 0.40 for air, 0.35 for argon, and 3.46 for helium.

Discussion We are assuming, of course, that these gases behave as ideal gases – a good approximation at room temperature.

17-14C We are to compare the speed of sound in air at two different pressures, but the same temperature.

Analysis Air at specified conditions will behave like an ideal gas, and *the speed of sound in an ideal gas depends on temperature only*. Therefore, **the speed of sound is the same in both mediums**.

Discussion If the temperature were different, however, the speed of sound would be different.

17-15C We are to examine whether the Mach number remains constant in constant-velocity flow.

Analysis In general, **no**, because the Mach number also depends on the speed of sound in gas, which depends on the temperature of the gas. **The Mach number remains constant only if the temperature and the velocity are constant.**

Discussion It turns out that the speed of sound is not a strong function of pressure. In fact, it is not a function of pressure at all for an ideal gas.

17-16C We are to state whether the propagation of sound waves is an isentropic process.

Analysis **Yes, the propagation of sound waves is nearly isentropic.** Because the amplitude of an ordinary sound wave is very small, and it does not cause any significant change in temperature and pressure.

Discussion No process is truly isentropic, but the increase of entropy due to sound propagation is negligibly small.

17-17C We are to discuss sonic velocity – specifically, whether it is constant or it changes.

Analysis The *sonic speed* in a medium **depends on the properties of the medium, and it changes as the properties of the medium change.**

Discussion The most common example is the change in speed of sound due to temperature change.

17-18 The Mach number of a passenger plane for specified limiting operating conditions is to be determined.

Assumptions Air is an ideal gas with constant specific heats at room temperature.

Properties The gas constant of air is $R = 0.287 \text{ kJ/kg}\cdot\text{K}$. Its specific heat ratio at room temperature is $k = 1.4$.

Analysis From the speed of sound relation

$$c = \sqrt{kRT} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(-60 + 273 \text{ K})\left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}}\right)} = 293 \text{ m/s}$$

Thus, the Mach number corresponding to the maximum cruising speed of the plane is

$$\text{Ma} = \frac{V_{\max}}{c} = \frac{(945/3.6) \text{ m/s}}{293 \text{ m/s}} = \mathbf{0.897}$$

Discussion Note that this is a subsonic flight since $\text{Ma} < 1$. Also, using a k value at -60°C would give practically the same result.

17-19 Carbon dioxide flows through a nozzle. The inlet temperature and velocity and the exit temperature of CO_2 are specified. The Mach number is to be determined at the inlet and exit of the nozzle.

Assumptions **1** CO_2 is an ideal gas with constant specific heats at room temperature. **2** This is a steady-flow process.

Properties The gas constant of carbon dioxide is $R = 0.1889 \text{ kJ/kg}\cdot\text{K}$. Its constant pressure specific heat and specific heat ratio at room temperature are $c_p = 0.8439 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.288$.

Analysis (a) At the inlet

$$c_1 = \sqrt{k_1 R T_1} = \sqrt{(1.288)(0.1889 \text{ kJ/kg}\cdot\text{K})(1200 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 540.3 \text{ m/s}$$

Thus,

$$\text{Ma}_1 = \frac{V_1}{c_1} = \frac{50 \text{ m/s}}{540.3 \text{ m/s}} = \mathbf{0.0925}$$

(b) At the exit,

$$c_2 = \sqrt{k_2 R T_2} = \sqrt{(1.288)(0.1889 \text{ kJ/kg}\cdot\text{K})(400 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 312.0 \text{ m/s}$$

The nozzle exit velocity is determined from the steady-flow energy balance relation,

$$0 = h_2 - h_1 + \frac{V_2^2 - V_1^2}{2} \rightarrow 0 = c_p(T_2 - T_1) + \frac{V_2^2 - V_1^2}{2}$$

$$0 = (0.8439 \text{ kJ/kg}\cdot\text{K})(400 - 1200 \text{ K}) + \frac{V_2^2 - (50 \text{ m/s})^2}{2} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) \rightarrow V_2 = 1163 \text{ m/s}$$

Thus,

$$\text{Ma}_2 = \frac{V_2}{c_2} = \frac{1163 \text{ m/s}}{312 \text{ m/s}} = \mathbf{3.73}$$

Discussion The specific heats and their ratio k change with temperature, and the accuracy of the results can be improved by accounting for this variation. Using EES (or another property database):

$$\text{At } 1200 \text{ K: } c_p = 1.278 \text{ kJ/kg}\cdot\text{K}, k = 1.173 \rightarrow c_1 = 516 \text{ m/s}, V_1 = 50 \text{ m/s}, \text{Ma}_1 = 0.0969$$

$$\text{At } 400 \text{ K: } c_p = 0.9383 \text{ kJ/kg}\cdot\text{K}, k = 1.252 \rightarrow c_2 = 308 \text{ m/s}, V_2 = 1356 \text{ m/s}, \text{Ma}_2 = 4.41$$

Therefore, the constant specific heat assumption results in an error of **4.5%** at the inlet and **15.5%** at the exit in the Mach number, which are significant.

17-20 Nitrogen flows through a heat exchanger. The inlet temperature, pressure, and velocity and the exit pressure and velocity are specified. The Mach number is to be determined at the inlet and exit of the heat exchanger.

Assumptions 1 N_2 is an ideal gas. 2 This is a steady-flow process. 3 The potential energy change is negligible.

Properties The gas constant of N_2 is $R = 0.2968 \text{ kJ/kg}\cdot\text{K}$. Its constant pressure specific heat and specific heat ratio at room temperature are $c_p = 1.040 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$.

Analysis For the inlet,

$$c_1 = \sqrt{k_1 RT_1} = \sqrt{(1.400)(0.2968 \text{ kJ/kg}\cdot\text{K})(283 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 342.9 \text{ m/s}$$

Thus,

$$\text{Ma}_1 = \frac{V_1}{c_1} = \frac{100 \text{ m/s}}{342.9 \text{ m/s}} = \mathbf{0.292}$$

From the energy balance on the heat exchanger,

$$q_{\text{in}} = c_p(T_2 - T_1) + \frac{V_2^2 - V_1^2}{2}$$

$$120 \text{ kJ/kg} = (1.040 \text{ kJ/kg}\cdot\text{K})(T_2 - 10^\circ\text{C}) + \frac{(200 \text{ m/s})^2 - (100 \text{ m/s})^2}{2} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right)$$

It yields

$$T_2 = 111^\circ\text{C} = 384 \text{ K}$$

$$c_2 = \sqrt{k_2 RT_2} = \sqrt{(1.4)(0.2968 \text{ kJ/kg}\cdot\text{K})(384 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 399 \text{ m/s}$$

Thus,

$$\text{Ma}_2 = \frac{V_2}{c_2} = \frac{200 \text{ m/s}}{399 \text{ m/s}} = \mathbf{0.501}$$

Discussion The specific heats and their ratio k change with temperature, and the accuracy of the results can be improved by accounting for this variation. Using EES (or another property database):

$$\text{At } 10^\circ\text{C} : c_p = 1.038 \text{ kJ/kg}\cdot\text{K}, k = 1.400 \rightarrow c_1 = 343 \text{ m/s}, V_1 = 100 \text{ m/s}, \text{Ma}_1 = 0.292$$

$$\text{At } 111^\circ\text{C} : c_p = 1.041 \text{ kJ/kg}\cdot\text{K}, k = 1.399 \rightarrow c_2 = 399 \text{ m/s}, V_2 = 200 \text{ m/s}, \text{Ma}_2 = 0.501$$

Therefore, the constant specific heat assumption results in an error of **4.5%** at the inlet and **15.5%** at the exit in the Mach number, which are almost identical to the values obtained assuming constant specific heats.

17-21 The speed of sound in refrigerant-134a at a specified state is to be determined.

Assumptions R-134a is an ideal gas with constant specific heats at room temperature.

Properties The gas constant of R-134a is $R = 0.08149 \text{ kJ/kg}\cdot\text{K}$. Its specific heat ratio at room temperature is $k = 1.108$.

Analysis From the ideal-gas speed of sound relation,

$$c = \sqrt{kRT} = \sqrt{(1.108)(0.08149 \text{ kJ/kg}\cdot\text{K})(60 + 273 \text{ K})\left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}}\right)} = \mathbf{173 \text{ m/s}}$$

Discussion Note that the speed of sound is independent of pressure for ideal gases.

17-22 The Mach number of an aircraft and the speed of sound in air are to be determined at two specified temperatures.

Assumptions Air is an ideal gas with constant specific heats at room temperature.

Properties The gas constant of air is $R = 0.287 \text{ kJ/kg}\cdot\text{K}$. Its specific heat ratio at room temperature is $k = 1.4$.

Analysis From the definitions of the speed of sound and the Mach number,

(a) At 300 K,

$$c = \sqrt{kRT} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(300 \text{ K})\left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}}\right)} = \mathbf{347 \text{ m/s}}$$

and $\text{Ma} = \frac{V}{c} = \frac{330 \text{ m/s}}{347 \text{ m/s}} = \mathbf{0.951}$

(b) At 800 K,

$$c = \sqrt{kRT} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(800 \text{ K})\left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}}\right)} = \mathbf{567 \text{ m/s}}$$

and $\text{Ma} = \frac{V}{c} = \frac{330 \text{ m/s}}{567 \text{ m/s}} = \mathbf{0.582}$

Discussion Note that a constant Mach number does not necessarily indicate constant speed. The Mach number of a rocket, for example, will be increasing even when it ascends at constant speed. Also, the specific heat ratio k changes with temperature.

17-23E Steam flows through a device at a specified state and velocity. The Mach number of steam is to be determined assuming ideal gas behavior.

Assumptions Steam is an ideal gas with constant specific heats.

Properties The gas constant of steam is $R = 0.1102 \text{ Btu/lbm}\cdot\text{R}$. Its specific heat ratio is given to be $k = 1.3$.

Analysis From the ideal-gas speed of sound relation,

$$c = \sqrt{kRT} = \sqrt{(1.3)(0.1102 \text{ Btu/lbm}\cdot\text{R})(1160 \text{ R}) \left(\frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right)} = 2040 \text{ ft/s}$$

Thus,

$$\text{Ma} = \frac{V}{c} = \frac{900 \text{ ft/s}}{2040 \text{ ft/s}} = \mathbf{0.441}$$

Discussion Using property data from steam tables and not assuming ideal gas behavior, it can be shown that the Mach number in steam at the specified state is 0.446, which is sufficiently close to the ideal-gas value of 0.441. Therefore, the ideal gas approximation is a reasonable one in this case.

17-24E Problem 2-23E is reconsidered. The variation of Mach number with temperature as the temperature changes between 350° and 700°F is to be investigated, and the results are to be plotted.

Analysis The EES *Equations* window is printed below, along with the tabulated and plotted results.

```
T=Temperature+460
R=0.1102
V=900
k=1.3
c=SQRT(k*R*T*25037)
Ma=V/c
```

Temperature, <i>T</i> , °F	Mach number Ma
350	0.528
375	0.520
400	0.512
425	0.505
450	0.498
475	0.491
500	0.485
525	0.479
550	0.473
575	0.467
600	0.462
625	0.456
650	0.451
675	0.446
700	0.441

Discussion Note that for a specified flow speed, the Mach number decreases with increasing temperature, as expected.

17-25E The inlet state and the exit pressure of air are given for an isentropic expansion process. The ratio of the initial to the final speed of sound is to be determined.

Assumptions Air is an ideal gas with constant specific heats at room temperature.

Properties The properties of air are $R = 0.06855$ Btu/lbm·R and $k = 1.4$. The specific heat ratio k varies with temperature, but in our case this change is very small and can be disregarded.

Analysis The final temperature of air is determined from the isentropic relation of ideal gases,

$$T_2 = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (659.7 \text{ R}) \left(\frac{60}{170} \right)^{(1.4-1)/1.4} = 489.9 \text{ R}$$

Treating k as a constant, the ratio of the initial to the final speed of sound can be expressed as

$$\text{Ratio} = \frac{c_2}{c_1} = \frac{\sqrt{k_1 R T_1}}{\sqrt{k_2 R T_2}} = \frac{\sqrt{T_1}}{\sqrt{T_2}} = \frac{\sqrt{659.7}}{\sqrt{489.9}} = \mathbf{1.16}$$

Discussion Note that the speed of sound is proportional to the square root of thermodynamic temperature.

17-26 The inlet state and the exit pressure of air are given for an isentropic expansion process. The ratio of the initial to the final speed of sound is to be determined.

Assumptions Air is an ideal gas with constant specific heats at room temperature.

Properties The properties of air are $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$. The specific heat ratio k varies with temperature, but in our case this change is very small and can be disregarded.

Analysis The final temperature of air is determined from the isentropic relation of ideal gases,

$$T_2 = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (350.2 \text{ K}) \left(\frac{0.4 \text{ MPa}}{2.2 \text{ MPa}} \right)^{(1.4-1)/1.4} = 215.2 \text{ K}$$

Treating k as a constant, the ratio of the initial to the final speed of sound can be expressed as

$$\text{Ratio} = \frac{c_2}{c_1} = \frac{\sqrt{k_1 R T_1}}{\sqrt{k_2 R T_2}} = \frac{\sqrt{T_1}}{\sqrt{T_2}} = \frac{\sqrt{350.2}}{\sqrt{215.2}} = \mathbf{1.28}$$

Discussion Note that the speed of sound is proportional to the square root of thermodynamic temperature.

17-27 The inlet state and the exit pressure of helium are given for an isentropic expansion process. The ratio of the initial to the final speed of sound is to be determined.

Assumptions Helium is an ideal gas with constant specific heats at room temperature.

Properties The properties of helium are $R = 2.0769 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.667$.

Analysis The final temperature of helium is determined from the isentropic relation of ideal gases,

$$T_2 = T_1 \left(\frac{P_2}{P_1} \right)^{(k-1)/k} = (350.2 \text{ K}) \left(\frac{0.4}{2.2} \right)^{(1.667-1)/1.667} = 177.0 \text{ K}$$

The ratio of the initial to the final speed of sound can be expressed as

$$\text{Ratio} = \frac{c_2}{c_1} = \frac{\sqrt{k_1 R T_1}}{\sqrt{k_2 R T_2}} = \frac{\sqrt{T_1}}{\sqrt{T_2}} = \frac{\sqrt{350.2}}{\sqrt{177.0}} = \mathbf{1.41}$$

Discussion Note that the speed of sound is proportional to the square root of thermodynamic temperature.

17-28 The expression for the speed of sound for an ideal gas is to be obtained using the isentropic process equation and the definition of the speed of sound.

Analysis The isentropic relation $Pv^k = A$ where A is a constant can also be expressed as

$$P = A \left(\frac{1}{v} \right)^k = A \rho^k$$

Substituting it into the relation for the speed of sound,

$$c^2 = \left(\frac{\partial \mathcal{P}}{\partial \rho} \right)_s = \left(\frac{\partial (A \rho^k)}{\partial \rho} \right)_s = k A \rho^{k-1} = k (A \rho^k) / \rho = k (P / \rho) = k R T$$

since for an ideal gas $P = \rho R T$ or $R T = P / \rho$. Therefore, $c = \sqrt{k R T}$, which is the desired relation.

Discussion Notice that pressure has dropped out; the speed of sound in an ideal gas is *not* a function of pressure.

One Dimensional Isentropic Flow

17-29C We are to determine if it is possible to accelerate a gas to supersonic velocity in a converging nozzle.

Analysis **No**, it is not possible.

Discussion The only way to do it is to have first a converging nozzle, and then a diverging nozzle.

17-30C We are to discuss what happens to several variables when a subsonic gas enters a diverging duct.

Analysis (a) The **velocity decreases**. (b), (c), (d) The **temperature, pressure, and density of the fluid increase**.

Discussion The velocity decrease is opposite to what happens in supersonic flow.

17-31C We are to discuss the pressure at the throats of two different converging-diverging nozzles.

Analysis **The pressures at the two throats are identical.**

Discussion Since the gas has the same stagnation conditions, it also has the same sonic conditions at the throat.

17-32C We are to discuss what happens to several variables when a supersonic gas enters a converging duct.

Analysis (a) The **velocity decreases**. (b), (c), (d) The **temperature, pressure, and density of the fluid increase**.

Discussion The velocity decrease is opposite to what happens in subsonic flow.

17-33C We are to discuss what happens to several variables when a supersonic gas enters a diverging duct.

Analysis (a) The **velocity increases**. (b), (c), (d) The **temperature, pressure, and density of the fluid decrease**.

Discussion The velocity increase is opposite to what happens in subsonic flow.

17-34C We are to discuss what happens to the exit velocity and mass flow rate through a converging nozzle at sonic exit conditions when the nozzle exit area is reduced.

Analysis (a) The **exit velocity remains constant at sonic speed**, (b) the **mass flow rate through the nozzle decreases because of the reduced flow area**.

Discussion Without a diverging portion of the nozzle, a converging nozzle is limited to sonic velocity at the exit.

17-35C We are to discuss what happens to several variables when a subsonic gas enters a converging duct.

Analysis (a) The **velocity increases**. (b), (c), (d) The **temperature, pressure, and density of the fluid decrease**.

Discussion The velocity increase is opposite to what happens in supersonic flow.

17-36 Helium enters a converging-diverging nozzle at specified conditions. The lowest temperature and pressure that can be obtained at the throat of the nozzle are to be determined.

Assumptions **1** Helium is an ideal gas with constant specific heats. **2** Flow through the nozzle is steady, one-dimensional, and isentropic.

Properties The properties of helium are $k = 1.667$ and $c_p = 5.1926 \text{ kJ/kg}\cdot\text{K}$.

Analysis The lowest temperature and pressure that can be obtained at the throat are the critical temperature T^* and critical pressure P^* . First we determine the stagnation temperature T_0 and stagnation pressure P_0 ,

$$T_0 = T + \frac{V^2}{2c_p} = 800 \text{ K} + \frac{(100 \text{ m/s})^2}{2 \times 5.1926 \text{ kJ/kg}\cdot\text{K}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 801 \text{ K}$$

$$P_0 = P \left(\frac{T_0}{T} \right)^{k/(k-1)} = (0.7 \text{ MPa}) \left(\frac{801 \text{ K}}{800 \text{ K}} \right)^{1.667/(1.667-1)} = 0.702 \text{ MPa}$$

Thus,

$$T^* = T_0 \left(\frac{2}{k+1} \right) = (801 \text{ K}) \left(\frac{2}{1.667+1} \right) = \mathbf{601 \text{ K}}$$

and

$$P^* = P_0 \left(\frac{2}{k+1} \right)^{k/(k-1)} = (0.702 \text{ MPa}) \left(\frac{2}{1.667+1} \right)^{1.667/(1.667-1)} = \mathbf{0.342 \text{ MPa}}$$

Discussion These are the temperature and pressure that will occur at the throat when the flow past the throat is supersonic.

17-37 The speed of an airplane and the air temperature are given. It is to be determined if the speed of this airplane is subsonic or supersonic.

Assumptions Air is an ideal gas with constant specific heats at room temperature.

Properties The gas constant of air is $R = 0.287 \text{ kJ/kg} \cdot \text{K}$. Its specific heat ratio at room temperature is $k = 1.4$.

Analysis The temperature is $-50 + 273.15 = 223.15 \text{ K}$. The speed of sound is

$$c = \sqrt{kRT} = \sqrt{(1.4)(0.287 \text{ kJ/kg} \cdot \text{K})(223.15 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right) \left(\frac{3.6 \text{ km/h}}{1 \text{ m/s}} \right)} = 1077.97 \text{ km/h}$$

and

$$\text{Ma} = \frac{V}{c} = \frac{1050 \text{ km/h}}{1077.97 \text{ km/h}} = 0.9741 \text{ km/h} \cong \mathbf{0.974}$$

The speed of the airplane is **subsonic** since the Mach number is less than 1.

Discussion Subsonic airplanes stay sufficiently far from the Mach number of 1 to avoid the instabilities associated with transonic flights.

7-38 The critical temperature, pressure, and density of air and helium are to be determined at specified conditions.

Assumptions Air and Helium are ideal gases with constant specific heats at room temperature.

Properties The properties of air at room temperature are $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, $k = 1.4$, and $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$. The properties of helium at room temperature are $R = 2.0769 \text{ kJ/kg}\cdot\text{K}$, $k = 1.667$, and $c_p = 5.1926 \text{ kJ/kg}\cdot\text{K}$.

Analysis (a) Before we calculate the critical temperature T^* , pressure P^* , and density ρ^* , we need to determine the stagnation temperature T_0 , pressure P_0 , and density ρ_0 .

$$T_0 = 100^\circ\text{C} + \frac{V^2}{2c_p} = 100 + \frac{(250 \text{ m/s})^2}{2 \times 1.005 \text{ kJ/kg}\cdot^\circ\text{C}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 131.1^\circ\text{C}$$

$$P_0 = P \left(\frac{T_0}{T} \right)^{k/(k-1)} = (200 \text{ kPa}) \left(\frac{404.3 \text{ K}}{373.2 \text{ K}} \right)^{1.4/(1.4-1)} = 264.7 \text{ kPa}$$

$$\rho_0 = \frac{P_0}{RT_0} = \frac{264.7 \text{ kPa}}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(404.3 \text{ K})} = 2.281 \text{ kg/m}^3$$

Thus,

$$T^* = T_0 \left(\frac{2}{k+1} \right) = (404.3 \text{ K}) \left(\frac{2}{1.4+1} \right) = \mathbf{337 \text{ K}}$$

$$P^* = P_0 \left(\frac{2}{k+1} \right)^{k/(k-1)} = (264.7 \text{ kPa}) \left(\frac{2}{1.4+1} \right)^{1.4/(1.4-1)} = \mathbf{140 \text{ kPa}}$$

$$\rho^* = \rho_0 \left(\frac{2}{k+1} \right)^{1/(k-1)} = (2.281 \text{ kg/m}^3) \left(\frac{2}{1.4+1} \right)^{1/(1.4-1)} = \mathbf{1.45 \text{ kg/m}^3}$$

(b) For helium, $T_0 = T + \frac{V^2}{2c_p} = 40 + \frac{(300 \text{ m/s})^2}{2 \times 5.1926 \text{ kJ/kg}\cdot^\circ\text{C}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 48.7^\circ\text{C}$

$$P_0 = P \left(\frac{T_0}{T} \right)^{k/(k-1)} = (200 \text{ kPa}) \left(\frac{321.9 \text{ K}}{313.2 \text{ K}} \right)^{1.667/(1.667-1)} = 214.2 \text{ kPa}$$

$$\rho_0 = \frac{P_0}{RT_0} = \frac{214.2 \text{ kPa}}{(2.0769 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(321.9 \text{ K})} = 0.320 \text{ kg/m}^3$$

Thus,

$$T^* = T_0 \left(\frac{2}{k+1} \right) = (321.9 \text{ K}) \left(\frac{2}{1.667+1} \right) = \mathbf{241 \text{ K}}$$

$$P^* = P_0 \left(\frac{2}{k+1} \right)^{k/(k-1)} = (200 \text{ kPa}) \left(\frac{2}{1.667+1} \right)^{1.667/(1.667-1)} = \mathbf{97.4 \text{ kPa}}$$

$$\rho^* = \rho_0 \left(\frac{2}{k+1} \right)^{1/(k-1)} = (0.320 \text{ kg/m}^3) \left(\frac{2}{1.667+1} \right)^{1/(1.667-1)} = \mathbf{0.208 \text{ kg/m}^3}$$

Discussion These are the temperature, pressure, and density values that will occur at the throat when the flow past the throat is supersonic.

17-39E Air flows through a duct at a specified state and Mach number. The velocity and the stagnation pressure, temperature, and density of the air are to be determined.

Assumptions Air is an ideal gas with constant specific heats at room temperature.

Properties The properties of air are $R = 0.06855 \text{ Btu/lbm}\cdot\text{R} = 0.3704 \text{ psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R}$ and $k = 1.4$.

Analysis First, $T = 320 + 459.67 = 779.67 \text{ K}$. The speed of sound in air at the specified conditions is

$$c = \sqrt{kRT} = \sqrt{(1.4)(0.06855 \text{ Btu/lbm}\cdot\text{R})(779.67 \text{ R}) \left(\frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right)} = 1368.72 \text{ ft/s}$$

Thus,

$$V = \text{Ma} \times c = (0.7)(1368.72 \text{ ft/s}) = 958.10 \cong \mathbf{958 \text{ ft/s}}$$

Also,

$$\rho = \frac{P}{RT} = \frac{25 \text{ psia}}{(0.3704 \text{ psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R})(779.67 \text{ R})} = 0.086568 \text{ lbm/ft}^3$$

Then the stagnation properties are determined from

$$T_0 = T \left(1 + \frac{(k-1)\text{Ma}^2}{2} \right) = (779.67 \text{ R}) \left(1 + \frac{(1.4-1)(0.7)^2}{2} \right) = 856.08 \text{ R} \cong \mathbf{856 \text{ R}}$$

$$P_0 = P \left(\frac{T_0}{T} \right)^{k/(k-1)} = (25 \text{ psia}) \left(\frac{856.08 \text{ R}}{779.67 \text{ R}} \right)^{1.4/(1.4-1)} = 34.678 \text{ psia} \cong \mathbf{34.7 \text{ psia}}$$

$$\rho_0 = \rho \left(\frac{T_0}{T} \right)^{1/(k-1)} = (0.08656 \text{ lbm/ft}^3) \left(\frac{856.08 \text{ R}}{779.67 \text{ R}} \right)^{1/(1.4-1)} = 0.10936 \text{ lbm/ft}^3 \cong \mathbf{0.109 \text{ lbm/ft}^3}$$

Discussion Note that the temperature, pressure, and density of a gas increases during a stagnation process.

17-40 Air enters a converging-diverging nozzle at specified conditions. The lowest pressure that can be obtained at the throat of the nozzle is to be determined.

Assumptions **1** Air is an ideal gas with constant specific heats at room temperature. **2** Flow through the nozzle is steady, one-dimensional, and isentropic.

Properties The specific heat ratio of air at room temperature is $k = 1.4$.

Analysis The lowest pressure that can be obtained at the throat is the critical pressure P^* , which is determined from

$$P^* = P_0 \left(\frac{2}{k+1} \right)^{k/(k-1)} = (1200 \text{ kPa}) \left(\frac{2}{1.4+1} \right)^{1.4/(1.4-1)} = \mathbf{634 \text{ kPa}}$$

Discussion This is the pressure that occurs at the throat when the flow past the throat is supersonic.

17-41 The Mach number of scramjet and the air temperature are given. The speed of the engine is to be determined.

Assumptions Air is an ideal gas with constant specific heats at room temperature.

Properties The gas constant of air is $R = 0.287 \text{ kJ/kg}\cdot\text{K}$. Its specific heat ratio at room temperature is $k = 1.4$.

Analysis The temperature is $-20 + 273.15 = 253.15 \text{ K}$. The speed of sound is

$$c = \sqrt{kRT} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(253.15 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 318.93 \text{ m/s}$$

and

$$V = cMa = (318.93 \text{ m/s})(7) \left(\frac{3.6 \text{ km/h}}{1 \text{ m/s}} \right) = 8037 \text{ km/h} \cong \mathbf{8040 \text{ km/h}}$$

Discussion Note that extremely high speed can be achieved with scramjet engines. We cannot justify more than three significant digits in a problem like this.

17-42E The Mach number of scramjet and the air temperature are given. The speed of the engine is to be determined.

Assumptions Air is an ideal gas with constant specific heats at room temperature.

Properties The gas constant of air is $R = 0.06855 \text{ Btu/lbm}\cdot\text{R}$. Its specific heat ratio at room temperature is $k = 1.4$.

Analysis The temperature is $0 + 459.67 = 459.67 \text{ R}$. The speed of sound is

$$c = \sqrt{kRT} = \sqrt{(1.4)(0.06855 \text{ Btu/lbm}\cdot\text{R})(459.67 \text{ R}) \left(\frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right)} = 1050.95 \text{ ft/s}$$

and

$$V = cMa = (1050.95 \text{ ft/s})(7) \left(\frac{1 \text{ mi/h}}{1.46667 \text{ ft/s}} \right) = 5015.9 \text{ mi/h} \cong \mathbf{5020 \text{ mi/h}}$$

Discussion Note that extremely high speed can be achieved with scramjet engines. We cannot justify more than three significant digits in a problem like this.

17-43 Air flows through a duct. The state of the air and its Mach number are specified. The velocity and the stagnation pressure, temperature, and density of the air are to be determined.

Assumptions Air is an ideal gas with constant specific heats at room temperature.

Properties The properties of air at room temperature are $R = 0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$ and $k = 1.4$.

Analysis The speed of sound in air at the specified conditions is

$$c = \sqrt{kRT} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(373.2 \text{ K})\left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}}\right)} = 387.2 \text{ m/s}$$

Thus,

$$V = \text{Ma} \times c = (0.8)(387.2 \text{ m/s}) = \mathbf{310 \text{ m/s}}$$

Also,

$$\rho = \frac{P}{RT} = \frac{200 \text{ kPa}}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(373.2 \text{ K})} = 1.867 \text{ kg/m}^3$$

Then the stagnation properties are determined from

$$T_0 = T \left(1 + \frac{(k-1)\text{Ma}^2}{2} \right) = (373.2 \text{ K}) \left(1 + \frac{(1.4-1)(0.8)^2}{2} \right) = \mathbf{421 \text{ K}}$$

$$P_0 = P \left(\frac{T_0}{T} \right)^{k/(k-1)} = (200 \text{ kPa}) \left(\frac{421.0 \text{ K}}{373.2 \text{ K}} \right)^{1.4/(1.4-1)} = \mathbf{305 \text{ kPa}}$$

$$\rho_0 = \rho \left(\frac{T_0}{T} \right)^{1/(k-1)} = (1.867 \text{ kg/m}^3) \left(\frac{421.0 \text{ K}}{373.2 \text{ K}} \right)^{1/(1.4-1)} = \mathbf{2.52 \text{ kg/m}^3}$$

Discussion Note that both the pressure and temperature drop as the gas is accelerated as part of the internal energy of the gas is converted to kinetic energy.

17-44 Problem 17-43 is reconsidered. The effect of Mach number on the velocity and stagnation properties as the Ma is varied from 0.1 to 2 are to be investigated, and the results are to be plotted.

Analysis The EES *Equations* window is printed below, along with the tabulated and plotted results.

```
P=200

2.0	774.4	671.7	1564.9	8.118

Discussion Note that as Mach number increases, so does the flow velocity and stagnation temperature, pressure, and density.

17-45 An aircraft is designed to cruise at a given Mach number, elevation, and the atmospheric temperature. The stagnation temperature on the leading edge of the wing is to be determined.

Assumptions Air is an ideal gas with constant specific heats at room temperature.

Properties The properties of air are $R = 0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$, $c_p = 1.005 \text{ kJ}/\text{kg}\cdot\text{K}$, and $k = 1.4$.

Analysis The speed of sound in air at the specified conditions is

$$c = \sqrt{kRT} = \sqrt{(1.4)(0.287 \text{ kJ}/\text{kg}\cdot\text{K})(236.15 \text{ K})\left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ}/\text{kg}}\right)} = 308.0 \text{ m/s}$$

Thus,

$$V = \text{Ma} \times c = (1.1)(308.0 \text{ m/s}) = 338.8 \text{ m/s}$$

Then,

$$T_0 = T + \frac{V^2}{2c_p} = 236.15 + \frac{(338.8 \text{ m/s})^2}{2 \times 1.005 \text{ kJ}/\text{kg}\cdot\text{K}} \left(\frac{1 \text{ kJ}/\text{kg}}{1000 \text{ m}^2/\text{s}^2}\right) = \mathbf{293 \text{ K}}$$

Discussion Note that the temperature of a gas increases during a stagnation process as the kinetic energy is converted to enthalpy.

17-46 Quiescent carbon dioxide at a given state is accelerated isentropically to a specified Mach number. The temperature and pressure of the carbon dioxide after acceleration are to be determined.

Assumptions Carbon dioxide is an ideal gas with constant specific heats at room temperature.

Properties The specific heat ratio of the carbon dioxide at room temperature is $k = 1.288$.

Analysis The inlet temperature and pressure in this case is equivalent to the stagnation temperature and pressure since the inlet velocity of the carbon dioxide is said to be negligible. That is, $T_0 = T_i = 400 \text{ K}$ and $P_0 = P_i = 1200 \text{ kPa}$. Then,

$$T = T_0 \left(\frac{2}{2 + (k-1)\text{Ma}^2} \right) = (600 \text{ K}) \left(\frac{2}{2 + (1.288-1)(0.6)^2} \right) = 570.43 \text{ K} \cong \mathbf{570 \text{ K}}$$

and

$$P = P_0 \left(\frac{T}{T_0} \right)^{k/(k-1)} = (1200 \text{ kPa}) \left(\frac{570.43 \text{ K}}{600 \text{ K}} \right)^{1.288/(1.288-1)} = 957.23 \text{ K} \cong \mathbf{957 \text{ kPa}}$$

Discussion Note that both the pressure and temperature drop as the gas is accelerated as part of the internal energy of the gas is converted to kinetic energy.

Isentropic Flow Through Nozzles

17-47C We are to analyze if it is possible to accelerate a fluid to supersonic speeds with a velocity that is not sonic at the throat.

Analysis **No, if the flow in the throat is subsonic.** If the velocity at the throat is subsonic, the diverging section would act like a diffuser and decelerate the flow. **Yes, if the flow in the throat is already supersonic,** the diverging section would accelerate the flow to even higher Mach number.

Discussion In duct flow, the latter situation is not possible unless a second converging-diverging portion of the duct is located upstream, and there is sufficient pressure difference to choke the flow in the upstream throat.

17-48C We are to discuss what would happen if we add a diverging section to supersonic flow in a duct.

Analysis The fluid would **accelerate even further**, as desired.

Discussion This is the opposite of what would happen in subsonic flow.

17-49C We are to discuss the difference between Ma^* and Ma .

Analysis Ma^* is the **local velocity non-dimensionalized with respect to the sonic speed at the throat**, whereas Ma is the **local velocity non-dimensionalized with respect to the local sonic speed**.

Discussion The two are identical at the throat when the flow is choked.

17-50C We are to consider subsonic flow through a converging nozzle with critical pressure at the exit, and analyze the effect of lowering back pressure below the critical pressure.

Analysis (a) **No effect on velocity.** (b) **No effect on pressure.** (c) **No effect on mass flow rate.**

Discussion In this situation, the flow is already choked initially, so further lowering of the back pressure does not change anything upstream of the nozzle exit plane.

17-51C We are to compare the mass flow rates through two identical converging nozzles, but with one having a diverging section.

Analysis **If the back pressure is low enough so that sonic conditions exist at the throats, the mass flow rates in the two nozzles would be identical.** However, **if the flow is not sonic at the throat, the mass flow rate through the nozzle with the diverging section would be greater**, because it acts like a subsonic diffuser.

Discussion Once the flow is choked at the throat, whatever happens downstream is irrelevant to the flow upstream of the throat.

17-52C We are to discuss the hypothetical situation of hypersonic flow at the outlet of a converging nozzle.

Analysis Maximum flow rate through a converging nozzle is achieved when $Ma = 1$ at the exit of a nozzle. For all other Ma values the mass flow rate decreases. Therefore, **the mass flow rate would decrease if hypersonic velocities were achieved at the throat of a converging nozzle.**

Discussion Note that this is not possible unless the flow upstream of the converging nozzle is already hypersonic.

17-53C We are to consider subsonic flow through a converging nozzle, and analyze the effect of setting back pressure to critical pressure for a converging nozzle.

Analysis (a) The **exit velocity reaches the sonic speed**, (b) the **exit pressure equals the critical pressure**, and (c) the **mass flow rate reaches the maximum value**.

Discussion In such a case, we say that the flow is *choked*.

17-54C We are to discuss what happens to several variables in the diverging section of a subsonic converging-diverging nozzle.

Analysis (a) The **velocity decreases**, (b) the **pressure increases**, and (c) the **mass flow rate remains the same**.

Discussion Qualitatively, this is the same as what we are used to (in previous chapters) for incompressible flow.

17-55C We are to discuss what would happen if we add a diverging section to supersonic flow in a duct.

Analysis The fluid would **accelerate even further** instead of decelerating.

Discussion This is the opposite of what would happen in subsonic flow.

17-56 Nitrogen enters a converging-diverging nozzle at a given pressure. The critical velocity, pressure, temperature, and density in the nozzle are to be determined.

Assumptions 1 Nitrogen is an ideal gas. 2 Flow through the nozzle is steady, one-dimensional, and isentropic.

Properties The properties of nitrogen are $k = 1.4$ and $R = 0.2968 \text{ kJ/kg}\cdot\text{K}$.

Analysis The stagnation pressure in this case are identical to the inlet properties since the inlet velocity is negligible. They remain constant throughout the nozzle,

$$P_0 = P_i = 700 \text{ kPa}$$

$$T_0 = T_i = 400 \text{ K}$$

$$\rho_0 = \frac{P_0}{RT_0} = \frac{700 \text{ kPa}}{(0.2968 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(400 \text{ K})} = 5.896 \text{ kg/m}^3$$

Critical properties are those at a location where the Mach number is $\text{Ma} = 1$. From Table A-32 at $\text{Ma} = 1$, we read $T/T_0 = 0.8333$, $P/P_0 = 0.5283$, and $\rho/\rho_0 = 0.6339$. Then the critical properties become

$$T^* = 0.8333T_0 = 0.8333(400 \text{ K}) = \mathbf{333 \text{ K}}$$

$$P^* = 0.5283P_0 = 0.5283(700 \text{ kPa}) = \mathbf{370 \text{ MPa}}$$

$$\rho^* = 0.6339\rho_0 = 0.6339(5.896 \text{ kg/m}^3) = \mathbf{3.74 \text{ kg/m}^3}$$

Also,

$$V^* = c^* = \sqrt{kRT^*} = \sqrt{(1.4)(0.2968 \text{ kJ/kg}\cdot\text{K})(333 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = \mathbf{372 \text{ m/s}}$$

Discussion We can also solve this problem using the relations for compressible isentropic flow. The results would be identical.

17-57 For an ideal gas, an expression is to be obtained for the ratio of the speed of sound where $\text{Ma} = 1$ to the speed of sound based on the stagnation temperature, c^*/c_0 .

Analysis For an ideal gas the speed of sound is expressed as $c = \sqrt{kRT}$. Thus,

$$\frac{c^*}{c_0} = \frac{\sqrt{kRT^*}}{\sqrt{kRT_0}} = \left(\frac{T^*}{T_0} \right)^{1/2} = \left(\frac{\mathbf{2}}{\mathbf{k+1}} \right)^{1/2}$$

Discussion Note that a speed of sound changes the flow as the temperature changes.

17-58 Air enters a converging-diverging nozzle at a specified pressure. The back pressure that will result in a specified exit Mach number is to be determined.

Assumptions 1 Air is an ideal gas with constant specific heats. 2 Flow through the nozzle is steady, one-dimensional, and isentropic.

Properties The specific heat ratio of air is $k = 1.4$.

Analysis The stagnation pressure in this case is identical to the inlet pressure since the inlet velocity is negligible. It remains constant throughout the nozzle since the flow is isentropic,

$$P_0 = P_i = 1.2 \text{ MPa}$$

From Table A-32 at $\text{Ma}_e = 1.8$, we read $P_e/P_0 = 0.1740$.

Thus,

$$P = 0.1740P_0 = 0.1740(1.2 \text{ MPa}) = \mathbf{0.209 \text{ MPa} = 209 \text{ kPa}}$$

Discussion If we solve this problem using the relations for compressible isentropic flow, the results would be identical.

17-59E Air enters a nozzle at specified temperature, pressure, and velocity. The exit pressure, exit temperature, and exit-to-inlet area ratio are to be determined for a Mach number of $\text{Ma} = 1$ at the exit.

Assumptions 1 Air is an ideal gas with constant specific heats at room temperature. 2 Flow through the nozzle is steady, one-dimensional, and isentropic.

Properties The properties of air are $k = 1.4$ and $c_p = 0.240 \text{ Btu/lbm} \cdot \text{R}$ (Table A-2Ea).

Analysis The properties of the fluid at the location where $\text{Ma} = 1$ are the critical properties, denoted by superscript *. We first determine the stagnation temperature and pressure, which remain constant throughout the nozzle since the flow is isentropic.

$$T_0 = T + \frac{V_i^2}{2c_p} = 630 \text{ R} + \frac{(450 \text{ ft/s})^2}{2 \times 0.240 \text{ Btu/lbm} \cdot \text{R}} \left(\frac{1 \text{ Btu/lbm}}{25,037 \text{ ft}^2/\text{s}^2} \right) = 646.9 \text{ R}$$

$$P_0 = P_i \left(\frac{T_0}{T_i} \right)^{k/(k-1)} = (30 \text{ psia}) \left(\frac{646.9 \text{ K}}{630 \text{ K}} \right)^{1.4/(1.4-1)} = 32.9 \text{ psia}$$

From Table A-32 (or from Eqs. 12-18 and 12-19) at $\text{Ma} = 1$, we read $T/T_0 = 0.8333$, $P/P_0 = 0.5283$. Thus,

$$T = 0.8333T_0 = 0.8333(646.9 \text{ R}) = \mathbf{539 \text{ R}} \quad \text{and} \quad P = 0.5283P_0 = 0.5283(32.9 \text{ psia}) = \mathbf{17.4 \text{ psia}}$$

Also,

$$c_i = \sqrt{kRT_i} = \sqrt{(1.4)(0.06855 \text{ Btu/lbm} \cdot \text{R})(630 \text{ R}) \left(\frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right)} = 1230 \text{ ft/s} \quad \text{and}$$

$$\text{Ma}_i = \frac{V_i}{c_i} = \frac{450 \text{ ft/s}}{1230 \text{ ft/s}} = 0.3657$$

From Table A-32 at this Mach number we read $A_i/A^* = 1.7426$. Thus the ratio of the throat area to the nozzle inlet area is

$$\frac{A^*}{A_i} = \frac{1}{1.7426} = \mathbf{0.574}$$

Discussion If we solve this problem using the relations for compressible isentropic flow, the results would be identical.

17-60 For subsonic flow at the inlet, the variation of pressure, velocity, and Mach number along the length of the nozzle are to be sketched for an ideal gas under specified conditions.

Assumptions 1 The gas is an ideal gas. 2 Flow through the nozzle is steady, one-dimensional, and isentropic. 3 The flow is choked at the throat.

Analysis Using EES and CO₂ as the gas, we calculate and plot flow area A , velocity V , and Mach number Ma as the pressure drops from a stagnation value of 1400 kPa to 200 kPa. Note that the curve for A is related to the shape of the nozzle, with horizontal axis serving as the centerline. The EES equation window and the plot are shown below.

```

k=1.289
Cp=0.846 "kJ/kg.K"
R=0.1889 "kJ/kg.K"
P0=1400 "kPa"

T0=473 "K"
m=3 "kg/s"
rho_0=P0/(R*T0)
rho=P/(R*T)
rho_norm=rho/rho_0 "Normalized density"
T=T0*(P/P0)^((k-1)/k)
Tnorm=T/T0 "Normalized temperature"
V=SQRT(2*Cp*(T0-T)*1000)
V_norm=V/500
A=m/(rho*V)*500
C=SQRT(k*R*T*1000)
Ma=V/C
  
```

Discussion We are assuming that the back pressure is sufficiently low that the flow is choked at the throat, and the flow downstream of the throat is supersonic without any shock waves. Mach number and velocity continue to rise right through the throat into the diverging portion of the nozzle, since the flow becomes supersonic.

17-61 We repeat the previous problem, but for supersonic flow at the inlet. The variation of pressure, velocity, and Mach number along the length of the nozzle are to be sketched for an ideal gas under specified conditions.

Analysis Using EES and CO₂ as the gas, we calculate and plot flow area A , velocity V , and Mach number Ma as the pressure rises from 200 kPa at a very high velocity to the stagnation value of 1400 kPa. Note that the curve for A is related to the shape of the nozzle, with horizontal axis serving as the centerline.

$k=1.289$
 $C_p=0.846$ "kJ/kg.K"
 $R=0.1889$ "kJ/kg.K"
 $P_0=1400$ "kPa"

$T_0=473$ "K"
 $m=3$ "kg/s"
 $\rho_0=P_0/(R*T_0)$
 $\rho=P/(R*T)$
 $\rho_{norm}=\rho/\rho_0$ "Normalized density"
 $T=T_0*(P/P_0)^{((k-1)/k)}$
 $T_{norm}=T/T_0$ "Normalized temperature"
 $V=\text{SQRT}(2*C_p*(T_0-T)*1000)$
 $V_{norm}=V/500$
 $A=m/(\rho*V)*500$
 $C=\text{SQRT}(k*R*T*1000)$
 $Ma=V/C$

Discussion Note that this problem is identical to the proceeding one, except the flow direction is reversed. In fact, when plotted like this, the plots are identical.

17-62 It is to be explained why the maximum flow rate per unit area for a given ideal gas depends only on $P_0 / \sqrt{T_0}$. Also for an ideal gas, a relation is to be obtained for the constant a in $\dot{m}_{\max} / A^* = a \left(P_0 / \sqrt{T_0} \right)$.

Properties The properties of the ideal gas considered are $R = 0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$ and $k = 1.4$.

Analysis The maximum flow rate is given by

$$\dot{m}_{\max} = A^* P_0 \sqrt{k/R T_0} \left(\frac{2}{k+1} \right)^{(k+1)/2(k-1)} \quad \text{or} \quad \dot{m}_{\max} / A^* = \left(P_0 / \sqrt{T_0} \right) \sqrt{k/R} \left(\frac{2}{k+1} \right)^{(k+1)/2(k-1)}$$

For a given gas, k and R are fixed, and thus the mass flow rate depends on the parameter $P_0 / \sqrt{T_0}$. Thus, \dot{m}_{\max} / A^* can be expressed as $\dot{m}_{\max} / A^* = a \left(P_0 / \sqrt{T_0} \right)$ where

$$a = \sqrt{k/R} \left(\frac{2}{k+1} \right)^{(k+1)/2(k-1)} = \sqrt{\frac{1.4}{(0.287 \text{ kJ/kg}\cdot\text{K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)}} \left(\frac{2}{1.4+1} \right)^{2.4/0.8} = \mathbf{0.0404 \text{ (m/s)}\sqrt{\text{K}}}$$

Discussion Note that when sonic conditions exist at a throat of known cross-sectional area, the mass flow rate is fixed by the stagnation conditions.

17-63 An ideal gas is flowing through a nozzle. The flow area at a location where $\text{Ma} = 1.8$ is specified. The flow area where $\text{Ma} = 0.9$ is to be determined.

Assumptions Flow through the nozzle is steady, one-dimensional, and isentropic.

Properties The specific heat ratio is given to be $k = 1.4$.

Analysis The flow is assumed to be isentropic, and thus the stagnation and critical properties remain constant throughout the nozzle. The flow area at a location where $\text{Ma}_2 = 0.9$ is determined using A/A^* data from Table A-32 to be

$$\text{Ma}_1 = 1.8: \quad \frac{A_1}{A^*} = 1.4390 \longrightarrow A^* = \frac{A_1}{1.4390} = \frac{36 \text{ cm}^2}{1.4390} = 25.02 \text{ cm}^2$$

$$\text{Ma}_2 = 0.9: \quad \frac{A_2}{A^*} = 1.0089 \longrightarrow A_2 = (1.0089)A^* = (1.0089)(25.02 \text{ cm}^2) = \mathbf{25.2 \text{ cm}^2}$$

Discussion We can also solve this problem using the relations for compressible isentropic flow. The results would be identical.

17-64 An ideal gas is flowing through a nozzle. The flow area at a location where $Ma = 1.8$ is specified. The flow area where $Ma = 0.9$ is to be determined.

Assumptions Flow through the nozzle is steady, one-dimensional, and isentropic.

Analysis The flow is assumed to be isentropic, and thus the stagnation and critical properties remain constant throughout the nozzle. The flow area at a location where $Ma_2 = 0.9$ is determined using the A/A^* relation,

$$\frac{A}{A^*} = \frac{1}{Ma} \left\{ \left(\frac{2}{k+1} \right) \left(1 + \frac{k-1}{2} Ma^2 \right) \right\}^{(k+1)/2(k-1)}$$

For $k = 1.33$ and $Ma_1 = 1.8$:

$$\frac{A_1}{A^*} = \frac{1}{1.8} \left\{ \left(\frac{2}{1.33+1} \right) \left(1 + \frac{1.33-1}{2} 1.8^2 \right) \right\}^{2.33/2 \times 0.33} = 1.4696$$

and,
$$A^* = \frac{A_1}{2.570} = \frac{36 \text{ cm}^2}{1.4696} = 24.50 \text{ cm}^2$$

For $k = 1.33$ and $Ma_2 = 0.9$:

$$\frac{A_2}{A^*} = \frac{1}{0.9} \left\{ \left(\frac{2}{1.33+1} \right) \left(1 + \frac{1.33-1}{2} 0.9^2 \right) \right\}^{2.33/2 \times 0.33} = 1.0091$$

and
$$A_2 = (1.0091)A^* = (1.0091)(24.50 \text{ cm}^2) = \mathbf{24.7 \text{ cm}^2}$$

Discussion Note that the compressible flow functions in Table A-32 are prepared for $k = 1.4$, and thus they cannot be used to solve this problem.

17-65E Air enters a converging-diverging nozzle at a specified temperature and pressure with low velocity. The pressure, temperature, velocity, and mass flow rate are to be calculated in the specified test section.

Assumptions 1 Air is an ideal gas. 2 Flow through the nozzle is steady, one-dimensional, and isentropic.

Properties The properties of air are $k = 1.4$ and $R = 0.06855 \text{ Btu/lbm}\cdot\text{R} = 0.3704 \text{ psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R}$.

Analysis The stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible. They remain constant throughout the nozzle since the flow is isentropic.

$$P_0 = P_i = 150 \text{ psia} \quad \text{and} \quad T_0 = T_i = 100^\circ\text{F} \approx 560 \text{ R}$$

Then,

$$T_e = T_0 \left(\frac{2}{2 + (k-1)\text{Ma}^2} \right) = (560 \text{ R}) \left(\frac{2}{2 + (1.4-1)2^2} \right) = \mathbf{311 \text{ R}}$$

$$P_e = P_0 \left(\frac{T}{T_0} \right)^{k/(k-1)} = (150 \text{ psia}) \left(\frac{311}{560} \right)^{1.4/0.4} = \mathbf{19.1 \text{ psia}}$$

$$\rho_e = \frac{P_e}{RT_e} = \frac{19.1 \text{ psia}}{(0.3704 \text{ psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R})(311 \text{ R})} = 0.1661 \text{ lbm/ft}^3$$

The nozzle exit velocity can be determined from $V_e = \text{Ma}_e c_e$, where c_e is the speed of sound at the exit conditions,

$$V_e = \text{Ma}_e c_e = \text{Ma}_e \sqrt{kRT_e} = (2) \sqrt{(1.4)(0.06855 \text{ Btu/lbm}\cdot\text{R})(311 \text{ R}) \left(\frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right)} = 1729 \text{ ft/s} \approx \mathbf{1730 \text{ ft/s}}$$

Finally,

$$\dot{m} = \rho_e A_e V_e = (0.1661 \text{ lbm/ft}^3)(5 \text{ ft}^2)(1729 \text{ ft/s}) = 1435 \text{ lbm/s} \approx \mathbf{1440 \text{ lbm/s}}$$

Discussion Air must be very dry in this application because the exit temperature of air is extremely low, and any moisture in the air will turn to ice particles.

17-66 Air enters a nozzle at specified temperature, pressure, and velocity. The exit pressure, exit temperature, and exit-to-inlet area ratio are to be determined for a Mach number of $Ma = 1$ at the exit.

Assumptions **1** Air is an ideal gas with constant specific heats at room temperature. **2** Flow through the nozzle is steady, one-dimensional, and isentropic.

Properties The properties of air are $k = 1.4$ and $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$.

Analysis The properties of the fluid at the location where $Ma = 1$ are the critical properties, denoted by superscript *. We first determine the stagnation temperature and pressure, which remain constant throughout the nozzle since the flow is isentropic.

$$T_0 = T_i + \frac{V_i^2}{2c_p} = 420 \text{ K} + \frac{(110 \text{ m/s})^2}{2 \times 1.005 \text{ kJ/kg}\cdot\text{K}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 426.02$$

and

$$P_0 = P \left(\frac{T_0}{T} \right)^{k/(k-1)} = (0.5 \text{ MPa}) \left(\frac{426.02 \text{ K}}{420 \text{ K}} \right)^{1.4/(1.4-1)} = 0.52554 \text{ MPa}$$

From Table A-32 (or from Eqs. 12-18 and 12-19) at $Ma = 1$, we read $T/T_0 = 0.8333$, $P/P_0 = 0.5283$. Thus,

$$T = 0.8333T_0 = 0.8333(426.02 \text{ K}) = 355.00 \text{ K} \approx \mathbf{355 \text{ K}}$$

and

$$P = 0.5283P_0 = 0.5283(0.52554 \text{ MPa}) = 0.27764 \text{ MPa} \approx \mathbf{0.278 \text{ MPa} = 278 \text{ kPa}}$$

Also,

$$c_i = \sqrt{kRT_i} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(420 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 410.799 \text{ m/s}$$

and

$$Ma_i = \frac{V_i}{c_i} = \frac{110 \text{ m/s}}{410.799 \text{ m/s}} = 0.2678$$

$$Ma_i = \frac{V_i}{c_i} = \frac{150 \text{ m/s}}{410.799 \text{ m/s}} = 0.3651$$

From Table A-32 at this Mach number we read $A_i/A^* = 2.3343$. Thus the ratio of the throat area to the nozzle inlet area is

$$\frac{A^*}{A} = \frac{1}{2.3343} = 0.42839 \cong \mathbf{0.428}$$

Discussion We can also solve this problem using the relations for compressible isentropic flow. The results would be identical.

17-67 Air enters a nozzle at specified temperature and pressure with low velocity. The exit pressure, exit temperature, and exit-to-inlet area ratio are to be determined for a Mach number of $Ma = 1$ at the exit.

Assumptions **1** Air is an ideal gas. **2** Flow through the nozzle is steady, one-dimensional, and isentropic.

Properties The specific heat ratio of air is $k = 1.4$.

Analysis The properties of the fluid at the location where $Ma = 1$ are the critical properties, denoted by superscript *. The stagnation temperature and pressure in this case are identical to the inlet temperature and pressure since the inlet velocity is negligible. They remain constant throughout the nozzle since the flow is isentropic.

$$T_0 = T_i = 420 \text{ K} \quad \text{and} \quad P_0 = P_i = 0.5 \text{ MPa}$$

From Table A-32 (or from Eqs. 12-18 and 12-19) at $Ma = 1$, we read $T/T_0 = 0.8333$, $P/P_0 = 0.5283$. Thus,

$$T = 0.8333T_0 = 0.8333(420 \text{ K}) = \mathbf{350 \text{ K}} \quad \text{and} \quad P = 0.5283P_0 = 0.5283(0.5 \text{ MPa}) = \mathbf{0.264 \text{ MPa}}$$

The Mach number at the nozzle inlet is $Ma = 0$ since $V_i \cong 0$. From Table A-32 at this Mach number we read $A_i/A^* = \infty$.

Thus the ratio of the throat area to the nozzle inlet area is $\frac{A^*}{A_i} = \frac{1}{\infty} = \mathbf{0}$.

Discussion If we solve this problem using the relations for compressible isentropic flow, the results would be identical.

17-68 Air enters a converging nozzle at a specified temperature and pressure with low velocity. The exit pressure, the exit velocity, and the mass flow rate versus the back pressure are to be calculated and plotted.

Assumptions **1** Air is an ideal gas with constant specific heats at room temperature. **2** Flow through the nozzle is steady, one-dimensional, and isentropic.

Properties The properties of air are $k = 1.4$, $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, and $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$.

Analysis The stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible. They remain constant throughout the nozzle since the flow is isentropic,

$$P_0 = P_i = 900 \text{ kPa}$$

$$T_0 = T_i = 400 \text{ K}$$

The critical pressure is determined to be

$$P^* = P_0 \left(\frac{2}{k+1} \right)^{k/(k-1)} = (900 \text{ kPa}) \left(\frac{2}{1.4+1} \right)^{1.4/0.4} = 475.5 \text{ kPa}$$

Then the pressure at the exit plane (throat) will be

$$P_e = P_b \quad \text{for} \quad P_b \geq 475.5 \text{ kPa}$$

$$P_e = P^* = 475.5 \text{ kPa} \quad \text{for} \quad P_b < 475.5 \text{ kPa} \quad (\text{choked flow})$$

Thus the back pressure will not affect the flow when $100 < P_b < 475.5 \text{ kPa}$. For a specified exit pressure P_e , the temperature, the velocity and the mass flow rate can be determined from

$$\text{Temperature} \quad T_e = T_0 \left(\frac{P_e}{P_0} \right)^{(k-1)/k} = (400 \text{ K}) \left(\frac{P_e}{900} \right)^{0.4/1.4}$$

$$\text{Velocity} \quad V = \sqrt{2c_p(T_0 - T_e)} = \sqrt{2(1.005 \text{ kJ/kg}\cdot\text{K})(400 - T_e) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)}$$

$$\text{Density} \quad \rho_e = \frac{P_e}{RT_e} = \frac{P_e}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})T_e}$$

$$\text{Mass flow rate} \quad \dot{m} = \rho_e V_e A_e = \rho_e V_e (0.001 \text{ m}^2)$$

The results of the calculations are tabulated as

P_b , kPa	P_e , kPa	T_e , K	V_e , m/s	ρ_e , kg/m ³	\dot{m} kg/s
900	900	400	0	7.840	0
800	800	386.8	162.9	7.206	1.174
700	700	372.3	236.0	6.551	1.546
600	600	356.2	296.7	5.869	1.741
500	500	338.2	352.4	5.151	1.815
475.5	475.5	333.3	366.2	4.971	1.820
400	475.5	333.3	366.2	4.971	1.820
300	475.5	333.3	366.2	4.971	1.820
200	475.5	333.3	366.2	4.971	1.820
100	475.5	333.3	366.2	4.971	1.820

Discussion We see from the plots that once the flow is choked at a back pressure of 475.5 kPa, the mass flow rate remains constant regardless of how low the back pressure gets.

17-69 We are to reconsider the previous problem. Using EES (or other) software, we are to solve the problem for the inlet conditions of 0.8 MPa and 1200 K.

Analysis Air at 800 kPa, 1200 K enters a converging nozzle with a negligible velocity. The throat area of the nozzle is 10 cm². Assuming isentropic flow, calculate and plot the exit pressure, the exit velocity, and the mass flow rate versus the back pressure P_b for $0.8 \geq P_b \geq 0.1$ MPa.

```

Discussion We see from the plot that once the flow is choked at a back pressure of 422.7 kPa, the mass flow rate remains constant regardless of how low the back pressure gets.

Shock Waves and Expansion Waves

17-70C We are to discuss the applicability of the isentropic flow relations across shocks and expansion waves.

Analysis The isentropic relations of ideal gases are **not applicable for flows across (a) normal shock waves and (b) oblique shock waves**, but they **are applicable for flows across (c) Prandtl-Meyer expansion waves**.

Discussion Flow across any kind of shock wave involves irreversible losses – hence, it cannot be isentropic.

17-71C We are to discuss the states on the Fanno and Rayleigh lines.

Analysis The *Fanno line* represents the **states that satisfy the conservation of mass and energy equations**. The *Rayleigh line* represents the **states that satisfy the conservation of mass and momentum equations**. The *intersections* points of these lines represent the **states that satisfy the conservation of mass, energy, and momentum equations**.

Discussion *T-s* diagrams are quite helpful in understanding these kinds of flows.

17-72C We are to analyze a claim about oblique shock analysis.

Analysis **Yes, the claim is correct.** Conversely, normal shocks can be thought of as special oblique shocks in which the shock angle is $\beta = \pi/2$, or 90° .

Discussion The component of flow in the direction normal to the oblique shock acts exactly like a normal shock. We can think of the flow parallel to the oblique shock as “going along for the ride” – it does not affect anything.

17-73C We are to discuss the effect of a normal shock wave on several properties.

Analysis (a) **velocity decreases**, (b) **static temperature increases**, (c) **stagnation temperature remains the same**, (d) **static pressure increases**, and (e) **stagnation pressure decreases**.

Discussion In addition, the Mach number goes from supersonic ($Ma > 1$) to subsonic ($Ma < 1$).

17-74C We are to discuss the formation of oblique shocks and how they differ from normal shocks.

Analysis *Oblique shocks* occur when **a gas flowing at supersonic speeds strikes a flat or inclined surface**. Normal shock waves are perpendicular to flow whereas inclined shock waves, as the name implies, are typically **inclined relative to the flow direction**. Also, normal shocks form a straight line whereas **oblique shocks can be straight or curved**, depending on the surface geometry.

Discussion In addition, while a normal shock must go from supersonic ($Ma > 1$) to subsonic ($Ma < 1$), the Mach number downstream of an oblique shock can be either supersonic or subsonic.

17-75C We are to discuss whether the flow upstream and downstream of an oblique shock needs to be supersonic.

Analysis **Yes**, the *upstream flow* has to be supersonic for an oblique shock to occur. **No**, the flow *downstream* of an oblique shock can be subsonic, sonic, and even supersonic.

Discussion The latter is not true for normal shocks. For a normal shock, the flow must always go from supersonic ($Ma > 1$) to subsonic ($Ma < 1$).

17-76C We are to determine if Ma downstream of a normal shock can be supersonic.

Analysis **No**, the second law of thermodynamics requires the flow after the shock to be subsonic.

Discussion A normal shock wave always goes from supersonic to subsonic in the flow direction.

17-77C We are to discuss shock detachment at the nose of a 2-D wedge-shaped body.

Analysis **When the wedge half-angle δ is greater than the maximum deflection angle θ_{\max}** , the shock becomes curved and detaches from the nose of the wedge, forming what is called a *detached oblique shock* or a *bow wave*. The numerical value of the shock angle at the nose is $\beta = 90^\circ$.

Discussion When δ is less than θ_{\max} , the oblique shock is attached to the nose.

17-78C We are to discuss the shock at the nose of a rounded body in supersonic flow.

Analysis When supersonic flow impinges on a blunt body like the rounded nose of an aircraft, the wedge half-angle δ at the nose is 90° , and an attached oblique shock cannot exist, regardless of Mach number. Therefore, **a detached oblique shock must occur in front of all such blunt-nosed bodies**, whether two-dimensional, axisymmetric, or fully three-dimensional.

Discussion Since $\delta = 90^\circ$ at the nose, δ is always greater than θ_{\max} , regardless of Ma or the shape of the rest of the body.

17-79C We are to discuss if a shock wave can develop in the converging section of a C-V nozzle.

Analysis **No**, because the flow must be supersonic before a shock wave can occur. The flow in the converging section of a nozzle is always subsonic.

Discussion A normal shock (if it is to occur) would occur in the supersonic (diverging) section of the nozzle.

17-80 Air flowing through a nozzle experiences a normal shock. Various properties are to be calculated before and after the shock.

Assumptions 1 Air is an ideal gas with constant specific heats. 2 Flow through the nozzle is steady, one-dimensional, and isentropic before the shock occurs.

Properties The properties of air at room temperature are $k = 1.4$, $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, and $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$.

Analysis The stagnation temperature and pressure before the shock are

$$T_{01} = T_1 + \frac{V_1^2}{2c_p} = 230 + \frac{(815 \text{ m/s})^2}{2(1.005 \text{ kJ/kg}\cdot\text{K})} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 560.5 \text{ K}$$

$$P_{01} = P_1 \left(\frac{T_{01}}{T_1} \right)^{k/(k-1)} = (26 \text{ kPa}) \left(\frac{560.5 \text{ K}}{230 \text{ K}} \right)^{1.4/(1.4-1)} = 587.3 \text{ kPa}$$

The velocity and the Mach number before the shock are determined from

$$c_1 = \sqrt{kRT_1} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(230 \text{ K})} \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right) = \mathbf{304.0 \text{ m/s}}$$

and

$$\text{Ma}_1 = \frac{V_1}{c_1} = \frac{815 \text{ m/s}}{304.0 \text{ m/s}} = \mathbf{2.681}$$

The fluid properties after the shock (denoted by subscript 2) are related to those before the shock through the functions listed in Table A-33. For $\text{Ma}_1 = 2.681$ we read

$$\text{Ma}_2 = \mathbf{0.4972} \quad \frac{P_{02}}{P_1} = 9.7330, \quad \frac{P_2}{P_1} = 8.2208, \quad \text{and} \quad \frac{T_2}{T_1} = 2.3230$$

Then the stagnation pressure P_{02} , static pressure P_2 , and static temperature T_2 , are determined to be

$$P_{02} = 9.7330P_1 = (9.7330)(26 \text{ kPa}) = \mathbf{253.1 \text{ kPa}}$$

$$P_2 = 8.2208P_1 = (8.2208)(26 \text{ kPa}) = \mathbf{213.7 \text{ kPa}}$$

$$T_2 = 2.3230T_1 = (2.3230)(230 \text{ K}) = \mathbf{534.3 \text{ K}}$$

The air velocity after the shock can be determined from $V_2 = \text{Ma}_2 c_2$, where c_2 is the speed of sound at the exit conditions after the shock,

$$V_2 = \text{Ma}_2 c_2 = \text{Ma}_2 \sqrt{kRT_2} = (0.4972) \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(534.3 \text{ K})} \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right) = \mathbf{230.4 \text{ m/s}}$$

Discussion This problem could also be solved using the relations for compressible flow and normal shock functions. The results would be identical.

17-81 Air flowing through a nozzle experiences a normal shock. The entropy change of air across the normal shock wave is to be determined.

Assumptions 1 Air is an ideal gas with constant specific heats. 2 Flow through the nozzle is steady, one-dimensional, and isentropic before the shock occurs.

Properties The properties of air at room temperature are $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ and $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$.

Analysis The entropy change across the shock is determined to be

$$\begin{aligned} s_2 - s_1 &= c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} \\ &= (1.005 \text{ kJ/kg}\cdot\text{K}) \ln(2.3230) - (0.287 \text{ kJ/kg}\cdot\text{K}) \ln(8.2208) \\ &= \mathbf{0.242 \text{ kJ/kg}\cdot\text{K}} \end{aligned}$$

Discussion A shock wave is a highly dissipative process, and the entropy generation is large during shock waves.

17-82 For an ideal gas flowing through a normal shock, a relation for V_2/V_1 in terms of k , Ma_1 , and Ma_2 is to be developed.

Analysis The conservation of mass relation across the shock is $\rho_1 V_1 = \rho_2 V_2$ and it can be expressed as

$$\frac{V_2}{V_1} = \frac{\rho_1}{\rho_2} = \frac{P_1 / RT_1}{P_2 / RT_2} = \left(\frac{P_1}{P_2} \right) \left(\frac{T_2}{T_1} \right)$$

From Eqs. 12-35 and 12-38,

$$\frac{V_2}{V_1} = \left(\frac{1 + k\text{Ma}_2^2}{1 + k\text{Ma}_1^2} \right) \left(\frac{1 + \text{Ma}_1^2(k-1)/2}{1 + \text{Ma}_2^2(k-1)/2} \right)$$

Discussion This is an important relation as it enables us to determine the velocity ratio across a normal shock when the Mach numbers before and after the shock are known.

17-83 Air enters a converging-diverging nozzle at a specified state. The required back pressure that produces a normal shock at the exit plane is to be determined for the specified nozzle geometry.

Assumptions 1 Air is an ideal gas. 2 Flow through the nozzle is steady, one-dimensional, and isentropic before the shock occurs. 3 The shock wave occurs at the exit plane.

Analysis The inlet stagnation pressure in this case is identical to the inlet pressure since the inlet velocity is negligible. Since the flow before the shock to be isentropic,

$$P_{01} = P_i = 2 \text{ MPa}$$

It is specified that $A/A^* = 3.5$. From Table A-32, Mach number and the pressure ratio which corresponds to this area ratio are the $Ma_1 = 2.80$ and $P_1/P_{01} = 0.0368$. The pressure ratio across the shock for this Ma_1 value is, from Table A-33, $P_2/P_1 = 8.98$. Thus the back pressure, which is equal to the static pressure at the nozzle exit, must be

$$P_2 = 8.98P_1 = 8.98 \times 0.0368P_{01} = 8.98 \times 0.0368 \times (2 \text{ MPa}) = \mathbf{0.661 \text{ MPa}}$$

Discussion We can also solve this problem using the relations for compressible flow and normal shock functions. The results would be identical.

17-84 Air enters a converging-diverging nozzle at a specified state. The required back pressure that produces a normal shock at the exit plane is to be determined for the specified nozzle geometry.

Assumptions 1 Air is an ideal gas. 2 Flow through the nozzle is steady, one-dimensional, and isentropic before the shock occurs.

Analysis The inlet stagnation pressure in this case is identical to the inlet pressure since the inlet velocity is negligible. Since the flow before the shock to be isentropic,

$$P_{0x} = P_i = 2 \text{ MPa}$$

It is specified that $A/A^* = 2$. From Table A-32, the Mach number and the pressure ratio which corresponds to this area ratio are the $Ma_1 = 2.20$ and $P_1/P_{01} = 0.0935$. The pressure ratio across the shock for this M_1 value is, from Table A-33, $P_2/P_1 = 5.48$. Thus the back pressure, which is equal to the static pressure at the nozzle exit, must be

$$P_2 = 5.48P_1 = 5.48 \times 0.0935P_{01} = 5.48 \times 0.0935 \times (2 \text{ MPa}) = \mathbf{1.02 \text{ MPa}}$$

Discussion We can also solve this problem using the relations for compressible flow and normal shock functions. The results would be identical.

17-85E Air flowing through a nozzle experiences a normal shock. Effect of the shock wave on various properties is to be determined. Analysis is to be repeated for helium.

Assumptions **1** Air and helium are ideal gases with constant specific heats. **2** Flow through the nozzle is steady, one-dimensional, and isentropic before the shock occurs.

Properties The properties of air are $k = 1.4$ and $R = 0.06855 \text{ Btu/lbm}\cdot\text{R}$, and the properties of helium are $k = 1.667$ and $R = 0.4961 \text{ Btu/lbm}\cdot\text{R}$.

Analysis The air properties upstream the shock are

$$\text{Ma}_1 = 2.5, P_1 = 10 \text{ psia}, \text{ and } T_1 = 440.5 \text{ R}$$

Fluid properties after the shock (denoted by subscript 2) are related to those before the shock through the functions listed in Table A-33. For $\text{Ma}_1 = 2.5$,

$$\text{Ma}_2 = \mathbf{0.513}, \frac{P_{02}}{P_1} = 8.5262, \frac{P_2}{P_1} = 7.125, \text{ and } \frac{T_2}{T_1} = 2.1375$$

Then the stagnation pressure P_{02} , static pressure P_2 , and static temperature T_2 , are determined to be

$$P_{02} = 8.5262P_1 = (8.5262)(10 \text{ psia}) = \mathbf{85.3 \text{ psia}}$$

$$P_2 = 7.125P_1 = (7.125)(10 \text{ psia}) = \mathbf{71.3 \text{ psia}}$$

$$T_2 = 2.1375T_1 = (2.1375)(440.5 \text{ R}) = \mathbf{942 \text{ R}}$$

The air velocity after the shock can be determined from $V_2 = \text{Ma}_2c_2$, where c_2 is the speed of sound at the exit conditions after the shock,

$$V_2 = \text{Ma}_2c_2 = \text{Ma}_2\sqrt{kRT_2} = (0.513)\sqrt{(1.4)(0.06855 \text{ Btu/lbm}\cdot\text{R})(941.6 \text{ R})\left(\frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}}\right)} = \mathbf{772 \text{ ft/s}}$$

We now repeat the analysis for helium. This time we cannot use the tabulated values in Table A-33 since k is not 1.4. Therefore, we have to calculate the desired quantities using the analytical relations,

$$\text{Ma}_2 = \left(\frac{\text{Ma}_1^2 + 2/(k-1)}{2\text{Ma}_1^2k/(k-1) - 1}\right)^{1/2} = \left(\frac{2.5^2 + 2/(1.667-1)}{2 \times 2.5^2 \times 1.667/(1.667-1) - 1}\right)^{1/2} = \mathbf{0.553}$$

$$\frac{P_2}{P_1} = \frac{1+k\text{Ma}_1^2}{1+k\text{Ma}_2^2} = \frac{1+1.667 \times 2.5^2}{1+1.667 \times 0.553^2} = 7.5632$$

$$\frac{T_2}{T_1} = \frac{1+\text{Ma}_1^2(k-1)/2}{1+\text{Ma}_2^2(k-1)/2} = \frac{1+2.5^2(1.667-1)/2}{1+0.553^2(1.667-1)/2} = 2.7989$$

$$\begin{aligned} \frac{P_{02}}{P_1} &= \left(\frac{1+k\text{Ma}_1^2}{1+k\text{Ma}_2^2}\right) \left(1+(k-1)\text{Ma}_2^2/2\right)^{k/(k-1)} \\ &= \left(\frac{1+1.667 \times 2.5^2}{1+1.667 \times 0.553^2}\right) \left(1+(1.667-1) \times 0.553^2/2\right)^{1.667/0.667} = 9.641 \end{aligned}$$

Thus, $P_{02} = 11.546P_1 = (11.546)(10 \text{ psia}) = \mathbf{115 \text{ psia}}$

$$P_2 = 7.5632P_1 = (7.5632)(10 \text{ psia}) = \mathbf{75.6 \text{ psia}}$$

$$T_2 = 2.7989T_1 = (2.7989)(440.5 \text{ R}) = \mathbf{1233 \text{ R}}$$

$$V_2 = \text{Ma}_2c_2 = \text{Ma}_2\sqrt{kRT_2} = (0.553)\sqrt{(1.667)(0.4961 \text{ Btu/lbm}\cdot\text{R})(1232.9 \text{ R})\left(\frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}}\right)} = \mathbf{2794 \text{ ft/s}}$$

Discussion This problem could also be solved using the relations for compressible flow and normal shock functions. The results would be identical.

17-86E We are to reconsider Prob. 12-85E. Using EES (or other) software, we are to study the effects of both air and helium flowing steadily in a nozzle when there is a normal shock at a Mach number in the range $2 < M_x < 3.5$. In addition to the required information, we are to calculate the entropy change of the air and helium across the normal shock, and tabulate the results in a parametric table.

Analysis We use EES to calculate the entropy change of the air and helium across the normal shock. The results are given in the Parametric Table for $2 < M_x < 3.5$.

```

Discussion In all cases, regardless of the fluid or the Mach number, entropy increases across a shock wave. This is because a shock wave involves irreversibilities.

17-87 Air flowing through a converging-diverging nozzle experiences a normal shock at the exit. The effect of the shock wave on various properties is to be determined.

Assumptions **1** Air is an ideal gas with constant specific heats. **2** Flow through the nozzle is steady, one-dimensional, and isentropic before the shock occurs. **3** The shock wave occurs at the exit plane.

Properties The properties of air are $k = 1.4$ and $R = 0.287 \text{ kJ/kg}\cdot\text{K}$.

Analysis The inlet stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible. Then,

$$P_{01} = P_i = 1 \text{ MPa}$$

$$T_{01} = T_i = 300 \text{ K}$$

Then,

$$T_1 = T_{01} \left(\frac{2}{2 + (k-1)\text{Ma}_1^2} \right) = (300 \text{ K}) \left(\frac{2}{2 + (1.4-1)2.4^2} \right) = 139.4 \text{ K}$$

and

$$P_1 = P_{01} \left(\frac{T_1}{T_0} \right)^{k/(k-1)} = (1 \text{ MPa}) \left(\frac{139.4}{300} \right)^{1.4/0.4} = 0.06840 \text{ MPa}$$

The fluid properties after the shock (denoted by subscript 2) are related to those before the shock through the functions listed in Table A-33. For $\text{Ma}_1 = 2.4$ we read

$$\text{Ma}_2 = 0.5231 \cong \mathbf{0.523}, \quad \frac{P_{02}}{P_{01}} = 0.5401, \quad \frac{P_2}{P_1} = 6.5533, \quad \text{and} \quad \frac{T_2}{T_1} = 2.0403$$

Then the stagnation pressure P_{02} , static pressure P_2 , and static temperature T_2 , are determined to be

$$P_{02} = 0.5401P_{01} = (0.5401)(1.0 \text{ MPa}) = \mathbf{0.540 \text{ MPa} = 540 \text{ kPa}}$$

$$P_2 = 6.5533P_1 = (6.5533)(0.06840 \text{ MPa}) = \mathbf{0.448 \text{ MPa} = 448 \text{ kPa}}$$

$$T_2 = 2.0403T_1 = (2.0403)(139.4 \text{ K}) = \mathbf{284 \text{ K}}$$

The air velocity after the shock can be determined from $V_2 = \text{Ma}_2 c_2$, where c_2 is the speed of sound at the exit conditions after the shock,

$$V_2 = \text{Ma}_2 c_2 = \text{Ma}_2 \sqrt{kRT_2} = (0.5231) \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(284 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = \mathbf{177 \text{ m/s}}$$

Discussion We can also solve this problem using the relations for normal shock functions. The results would be identical.

17-88 The entropy change of air across the shock for upstream Mach numbers between 0.5 and 1.5 is to be determined and plotted.

Assumptions 1 Air is an ideal gas. 2 Flow through the nozzle is steady, one-dimensional, and isentropic before the shock occurs.

Properties The properties of air are $k = 1.4$, $R = 0.287$ kJ/kg·K, and $c_p = 1.005$ kJ/kg·K.

Analysis The entropy change across the shock is determined to be

$$s_2 - s_1 = c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1}$$

where

$$\text{Ma}_2 = \left(\frac{\text{Ma}_1^2 + 2/(k-1)}{2\text{Ma}_1^2 k / (k-1) - 1} \right)^{1/2}, \quad \frac{P_2}{P_1} = \frac{1 + k\text{Ma}_1^2}{1 + k\text{Ma}_2^2},$$

and

$$\frac{T_2}{T_1} = \frac{1 + \text{Ma}_1^2(k-1)/2}{1 + \text{Ma}_2^2(k-1)/2}$$

The results of the calculations can be tabulated as

Ma_1	Ma_2	T_2/T_1	P_2/P_1	$s_2 - s_1$
0.5	2.6458	0.1250	0.4375	-1.853
0.6	1.8778	0.2533	0.6287	-1.247
0.7	1.5031	0.4050	0.7563	-0.828
0.8	1.2731	0.5800	0.8519	-0.501
0.9	1.1154	0.7783	0.9305	-0.231
1.0	1.0000	1.0000	1.0000	0.0
1.1	0.9118	1.0649	1.2450	0.0003
1.2	0.8422	1.1280	1.5133	0.0021
1.3	0.7860	1.1909	1.8050	0.0061
1.4	0.7397	1.2547	2.1200	0.0124
1.5	0.7011	1.3202	2.4583	0.0210

Discussion The total entropy change is negative for upstream Mach numbers Ma_1 less than unity. Therefore, normal shocks cannot occur when $\text{Ma}_1 < 1$.

17-89 Supersonic airflow approaches the nose of a two-dimensional wedge and undergoes a straight oblique shock. For a specified Mach number, the minimum shock angle and the maximum deflection angle are to be determined.

Assumptions Air is an ideal gas with a constant specific heat ratio of $k = 1.4$ (so that Fig. 17-43 is applicable).

Analysis For $Ma = 5$, we read from Fig. 12-41

$$\text{Minimum shock (or wave) angle: } \beta_{\min} = 12^\circ$$

$$\text{Maximum deflection (or turning) angle: } \theta_{\max} = 41.5^\circ$$

Discussion Note that the minimum shock angle decreases and the maximum deflection angle increases with increasing Mach number Ma_1 .

17-90 Air flowing at a specified supersonic Mach number undergoes an expansion turn. The Mach number, pressure, and temperature downstream of the sudden expansion along a wall are to be determined.

Assumptions 1 The flow is steady. 2 The boundary layer on the wedge is very thin. 3 Air is an ideal gas with constant specific heats.

Properties The specific heat ratio of air is $k = 1.4$.

Analysis On the basis of Assumption #2, we take the deflection angle as equal to the wedge half-angle, i.e., $\theta \approx \delta = 15^\circ$. Then the upstream and downstream Prandtl-Meyer functions are determined to be

$$\nu(Ma) = \sqrt{\frac{k+1}{k-1}} \tan^{-1} \left(\sqrt{\frac{k-1}{k+1} (Ma^2 - 1)} \right) - \tan^{-1} \left(\sqrt{Ma^2 - 1} \right)$$

Upstream:

$$\nu(Ma_1) = \sqrt{\frac{1.4+1}{1.4-1}} \tan^{-1} \left(\sqrt{\frac{1.4-1}{1.4+1} (3.6^2 - 1)} \right) - \tan^{-1} \left(\sqrt{3.6^2 - 1} \right) = 60.09^\circ$$

Then the downstream Prandtl-Meyer function becomes

$$\nu(Ma_2) = \theta + \nu(Ma_1) = 15^\circ + 60.09^\circ = 75.09^\circ$$

Ma_2 is found from the Prandtl-Meyer relation, which is now implicit:

$$\text{Downstream: } \nu(Ma_2) = \sqrt{\frac{1.4+1}{1.4-1}} \tan^{-1} \left(\sqrt{\frac{1.4-1}{1.4+1} Ma_2^2 - 1} \right) - \tan^{-1} \left(\sqrt{Ma_2^2 - 1} \right) = 75.09^\circ$$

Solution of this implicit equation gives $Ma_2 = 4.81$. Then the downstream pressure and temperature are determined from the isentropic flow relations:

$$P_2 = \frac{P_2/P_0}{P_1/P_0} P_1 = \frac{[1 + Ma_2^2(k-1)/2]^{-k/(k-1)}}{[1 + Ma_1^2(k-1)/2]^{-k/(k-1)}} P_1 = \frac{[1 + 4.81^2(1.4-1)/2]^{-1.4/0.4}}{[1 + 3.6^2(1.4-1)/2]^{-1.4/0.4}} (32 \text{ kPa}) = \mathbf{6.65 \text{ kPa}}$$

$$T_2 = \frac{T_2/T_0}{T_1/T_0} T_1 = \frac{[1 + Ma_2^2(k-1)/2]^{-1}}{[1 + Ma_1^2(k-1)/2]^{-1}} T_1 = \frac{[1 + 4.81^2(1.4-1)/2]^{-1}}{[1 + 3.6^2(1.4-1)/2]^{-1}} (240 \text{ K}) = \mathbf{153 \text{ K}}$$

Note that this is an expansion, and Mach number increases while pressure and temperature decrease, as expected.

Discussion There are compressible flow calculators on the Internet that solve these implicit equations that arise in the analysis of compressible flow, along with both normal and oblique shock equations; e.g., see www.aoe.vt.edu/~devenpor/aoe3114/calc.html.

17-91 Air flowing at a specified supersonic Mach number undergoes an expansion turn over a tilted wedge. The Mach number, pressure, and temperature downstream of the sudden expansion above the wedge are to be determined.

Assumptions 1 The flow is steady. 2 The boundary layer on the wedge is very thin. 3 Air is an ideal gas with constant specific heats.

Properties The specific heat ratio of air is $k = 1.4$.

Analysis On the basis of Assumption #2, the deflection angle is determined to be $\theta \approx \delta = 25^\circ - 10^\circ = 15^\circ$. Then the upstream and downstream Prandtl-Meyer functions are determined to be

$$\nu(\text{Ma}) = \sqrt{\frac{k+1}{k-1}} \tan^{-1} \left(\sqrt{\frac{k-1}{k+1} (\text{Ma}^2 - 1)} \right) - \tan^{-1} \left(\sqrt{\text{Ma}^2 - 1} \right)$$

Upstream:

$$\nu(\text{Ma}_1) = \sqrt{\frac{1.4+1}{1.4-1}} \tan^{-1} \left(\sqrt{\frac{1.4-1}{1.4+1} (2.4^2 - 1)} \right) - \tan^{-1} \left(\sqrt{2.4^2 - 1} \right) = 36.75^\circ$$

Then the downstream Prandtl-Meyer function becomes

$$\nu(\text{Ma}_2) = \theta + \nu(\text{Ma}_1) = 15^\circ + 36.75^\circ = 51.75^\circ$$

Now Ma_2 is found from the Prandtl-Meyer relation, which is now implicit:

$$\text{Downstream: } \nu(\text{Ma}_2) = \sqrt{\frac{1.4+1}{1.4-1}} \tan^{-1} \left(\sqrt{\frac{1.4-1}{1.4+1} (\text{Ma}_2^2 - 1)} \right) - \tan^{-1} \left(\sqrt{\text{Ma}_2^2 - 1} \right) = 51.75^\circ$$

It gives $\text{Ma}_2 = \mathbf{3.105}$. Then the downstream pressure and temperature are determined from the isentropic flow relations

$$P_2 = \frac{P_2/P_0}{P_1/P_0} P_1 = \frac{[1 + \text{Ma}_2^2(k-1)/2]^{-k/(k-1)}}{[1 + \text{Ma}_1^2(k-1)/2]^{-k/(k-1)}} P_1 = \frac{[1 + 3.105^2(1.4-1)/2]^{-1.4/0.4}}{[1 + 2.4^2(1.4-1)/2]^{-1.4/0.4}} (70 \text{ kPa}) = \mathbf{23.8 \text{ kPa}}$$

$$T_2 = \frac{T_2/T_0}{T_1/T_0} T_1 = \frac{[1 + \text{Ma}_2^2(k-1)/2]^{-1}}{[1 + \text{Ma}_1^2(k-1)/2]^{-1}} T_1 = \frac{[1 + 3.105^2(1.4-1)/2]^{-1}}{[1 + 2.4^2(1.4-1)/2]^{-1}} (260 \text{ K}) = \mathbf{191 \text{ K}}$$

Note that this is an expansion, and Mach number increases while pressure and temperature decrease, as expected.

Discussion There are compressible flow calculators on the Internet that solve these implicit equations that arise in the analysis of compressible flow, along with both normal and oblique shock equations; e.g., see

www.aoe.vt.edu/~devenpor/aoe3114/calc.html .

17-92 Air flowing at a specified supersonic Mach number undergoes a compression turn (an oblique shock) over a tilted wedge. The Mach number, pressure, and temperature downstream of the shock below the wedge are to be determined.

Assumptions 1 The flow is steady. 2 The boundary layer on the wedge is very thin. 3 Air is an ideal gas with constant specific heats.

Properties The specific heat ratio of air is $k = 1.4$.

Analysis On the basis of Assumption #2, the deflection angle is determined to be $\theta \approx \delta = 25^\circ + 10^\circ = 35^\circ$. Then the two values of oblique shock angle β are determined from

$$\tan \theta = \frac{2(\text{Ma}_1^2 \sin^2 \beta - 1) / \tan \beta}{\text{Ma}_1^2 (k + \cos 2\beta) + 2} \quad \rightarrow \quad \tan 12^\circ = \frac{2(3.4^2 \sin^2 \beta - 1) / \tan \beta}{3.4^2 (1.4 + \cos 2\beta) + 2}$$

which is implicit in β . Therefore, we solve it by an iterative approach or with an equation solver such as EES. It gives $\beta_{\text{weak}} = 49.86^\circ$ and $\beta_{\text{strong}} = 77.66^\circ$. Then for the case of strong oblique shock, the upstream “normal” Mach number $\text{Ma}_{1,n}$ becomes

$$\text{Ma}_{1,n} = \text{Ma}_1 \sin \beta = 5 \sin 77.66^\circ = 4.884$$

Also, the downstream normal Mach numbers $\text{Ma}_{2,n}$ become

$$\text{Ma}_{2,n} = \sqrt{\frac{(k-1)\text{Ma}_{1,n}^2 + 2}{2k\text{Ma}_{1,n}^2 - k + 1}} = \sqrt{\frac{(1.4-1)(4.884)^2 + 2}{2(1.4)(4.884)^2 - 1.4 + 1}} = 0.4169$$

The downstream pressure and temperature are determined to be

$$P_2 = P_1 \frac{2k\text{Ma}_{1,n}^2 - k + 1}{k + 1} = (70 \text{ kPa}) \frac{2(1.4)(4.884)^2 - 1.4 + 1}{1.4 + 1} = \mathbf{1940 \text{ kPa}}$$

$$T_2 = T_1 \frac{P_2}{P_1} \frac{\rho_1}{\rho_2} = T_1 \frac{P_2}{P_1} \frac{2 + (k-1)\text{Ma}_{1,n}^2}{(k+1)\text{Ma}_{1,n}^2} = (260 \text{ K}) \frac{1940 \text{ kPa}}{70 \text{ kPa}} \frac{2 + (1.4-1)(4.884)^2}{(1.4+1)(4.884)^2} = \mathbf{1450 \text{ K}}$$

The downstream Mach number is determined to be

$$\text{Ma}_2 = \frac{\text{Ma}_{2,n}}{\sin(\beta - \theta)} = \frac{0.4169}{\sin(77.66^\circ - 35^\circ)} = \mathbf{0.615}$$

Discussion Note that $\text{Ma}_{1,n}$ is supersonic and $\text{Ma}_{2,n}$ and Ma_2 are subsonic. Also note the huge rise in temperature and pressure across the strong oblique shock, and the challenges they present for spacecraft during reentering the earth’s atmosphere.

17-93E Air flowing at a specified supersonic Mach number is forced to turn upward by a ramp, and weak oblique shock forms. The wave angle, Mach number, pressure, and temperature after the shock are to be determined.

Assumptions 1 The flow is steady. 2 The boundary layer on the wedge is very thin. 3 Air is an ideal gas with constant specific heats.

Properties The specific heat ratio of air is $k = 1.4$.

Analysis On the basis of Assumption #2, we take the deflection angle as equal to the ramp, i.e., $\theta \approx \delta = 8^\circ$. Then the two values of oblique shock angle β are determined from

$$\tan \theta = \frac{2(\text{Ma}_1^2 \sin^2 \beta - 1) / \tan \beta}{\text{Ma}_1^2 (k + \cos 2\beta) + 2} \quad \rightarrow \quad \tan 8^\circ = \frac{2(2^2 \sin^2 \beta - 1) / \tan \beta}{2^2 (1.4 + \cos 2\beta) + 2}$$

which is implicit in β . Therefore, we solve it by an iterative approach or with an equation solver such as EES. It gives $\beta_{\text{weak}} = 37.21^\circ$ and $\beta_{\text{strong}} = 85.05^\circ$. Then for the case of weak oblique shock, the upstream “normal” Mach number $\text{Ma}_{1,n}$ becomes

$$\text{Ma}_{1,n} = \text{Ma}_1 \sin \beta = 2 \sin 37.21^\circ = 1.209$$

Also, the downstream normal Mach numbers $\text{Ma}_{2,n}$ become

$$\text{Ma}_{2,n} = \sqrt{\frac{(k-1)\text{Ma}_{1,n}^2 + 2}{2k\text{Ma}_{1,n}^2 - k + 1}} = \sqrt{\frac{(1.4-1)(1.209)^2 + 2}{2(1.4)(1.209)^2 - 1.4 + 1}} = 0.8363$$

The downstream pressure and temperature are determined to be

$$P_2 = P_1 \frac{2k\text{Ma}_{1,n}^2 - k + 1}{k + 1} = (12 \text{ psia}) \frac{2(1.4)(1.209)^2 - 1.4 + 1}{1.4 + 1} = \mathbf{18.5 \text{ psia}}$$

$$T_2 = T_1 \frac{P_2}{P_1} \frac{\rho_1}{\rho_2} = T_1 \frac{P_2}{P_1} \frac{2 + (k-1)\text{Ma}_{1,n}^2}{(k+1)\text{Ma}_{1,n}^2} = (490 \text{ R}) \frac{18.5 \text{ psia}}{12 \text{ psia}} \frac{2 + (1.4-1)(1.209)^2}{(1.4+1)(1.209)^2} = \mathbf{556 \text{ R}}$$

The downstream Mach number is determined to be

$$\text{Ma}_2 = \frac{\text{Ma}_{2,n}}{\sin(\beta - \theta)} = \frac{0.8363}{\sin(37.21^\circ - 8^\circ)} = \mathbf{1.71}$$

Discussion Note that $\text{Ma}_{1,n}$ is supersonic and $\text{Ma}_{2,n}$ is subsonic. However, Ma_2 is *supersonic* across the weak oblique shock (it is *subsonic* across the strong oblique shock).

17-94E Air flowing at a specified supersonic Mach number is forced to undergo a compression turn (an oblique shock). The Mach number, pressure, and temperature downstream of the oblique shock are to be determined.

Assumptions 1 The flow is steady. 2 The boundary layer on the wedge is very thin. 3 Air is an ideal gas with constant specific heats.

Properties The specific heat ratio of air is $k = 1.4$.

Analysis On the basis of Assumption #2, we take the deflection angle as equal to the wedge half-angle, i.e., $\theta \approx \delta = 15^\circ$. Then the two values of oblique shock angle β are determined from

$$\tan \theta = \frac{2(\text{Ma}_1^2 \sin^2 \beta - 1) / \tan \beta}{\text{Ma}_1^2 (k + \cos 2\beta) + 2} \rightarrow \tan 15^\circ = \frac{2(2^2 \sin^2 \beta - 1) / \tan \beta}{2^2 (1.4 + \cos 2\beta) + 2}$$

which is implicit in β . Therefore, we solve it by an iterative approach or with an equation solver such as EES. It gives $\beta_{\text{weak}} = 45.34^\circ$ and $\beta_{\text{strong}} = 79.83^\circ$. Then the upstream “normal” Mach number $\text{Ma}_{1,n}$ becomes

$$\text{Weak shock: } \text{Ma}_{1,n} = \text{Ma}_1 \sin \beta = 2 \sin 45.34^\circ = 1.423$$

$$\text{Strong shock: } \text{Ma}_{1,n} = \text{Ma}_1 \sin \beta = 2 \sin 79.83^\circ = 1.969$$

Also, the downstream normal Mach numbers $\text{Ma}_{2,n}$ become

$$\text{Weak shock: } \text{Ma}_{2,n} = \sqrt{\frac{(k-1)\text{Ma}_{1,n}^2 + 2}{2k\text{Ma}_{1,n}^2 - k + 1}} = \sqrt{\frac{(1.4-1)(1.423)^2 + 2}{2(1.4)(1.423)^2 - 1.4 + 1}} = 0.7304$$

$$\text{Strong shock: } \text{Ma}_{2,n} = \sqrt{\frac{(k-1)\text{Ma}_{1,n}^2 + 2}{2k\text{Ma}_{1,n}^2 - k + 1}} = \sqrt{\frac{(1.4-1)(1.969)^2 + 2}{2(1.4)(1.969)^2 - 1.4 + 1}} = 0.5828$$

The downstream pressure and temperature for each case are determined to be

$$\text{Weak shock: } P_2 = P_1 \frac{2k\text{Ma}_{1,n}^2 - k + 1}{k + 1} = (6 \text{ psia}) \frac{2(1.4)(1.423)^2 - 1.4 + 1}{1.4 + 1} = 17.57 \cong \mathbf{17.6 \text{ psia}}$$

$$T_2 = T_1 \frac{P_2}{P_1} \frac{\rho_1}{\rho_2} = T_1 \frac{P_2}{P_1} \frac{2 + (k-1)\text{Ma}_{1,n}^2}{(k+1)\text{Ma}_{1,n}^2} = (480 \text{ R}) \frac{17.57 \text{ psia}}{6 \text{ psia}} \frac{2 + (1.4-1)(1.423)^2}{(1.4+1)(1.423)^2} = 609.5 \text{ R} \cong \mathbf{610 \text{ R}}$$

$$\text{Strong shock: } P_2 = P_1 \frac{2k\text{Ma}_{1,n}^2 - k + 1}{k + 1} = (8 \text{ psia}) \frac{2(1.4)(1.969)^2 - 1.4 + 1}{1.4 + 1} = 34.85 \cong \mathbf{34.9 \text{ psia}}$$

$$T_2 = T_1 \frac{P_2}{P_1} \frac{\rho_1}{\rho_2} = T_1 \frac{P_2}{P_1} \frac{2 + (k-1)\text{Ma}_{1,n}^2}{(k+1)\text{Ma}_{1,n}^2} = (480 \text{ R}) \frac{34.85 \text{ psia}}{8 \text{ psia}} \frac{2 + (1.4-1)(1.969)^2}{(1.4+1)(1.969)^2} = 797.9 \text{ R} \cong \mathbf{798 \text{ R}}$$

The downstream Mach number is determined to be

$$\text{Weak shock: } \text{Ma}_2 = \frac{\text{Ma}_{2,n}}{\sin(\beta - \theta)} = \frac{0.7304}{\sin(45.34^\circ - 15^\circ)} = \mathbf{1.45}$$

$$\text{Strong shock: } \text{Ma}_2 = \frac{\text{Ma}_{2,n}}{\sin(\beta - \theta)} = \frac{0.5828}{\sin(79.83^\circ - 15^\circ)} = \mathbf{0.644}$$

Discussion Note that the change in Mach number, pressure, temperature across the *strong shock* are much greater than the changes across the *weak shock*, as expected. For both the weak and strong oblique shock cases, $\text{Ma}_{1,n}$ is supersonic and $\text{Ma}_{2,n}$ is subsonic. However, Ma_2 is *supersonic* across the weak oblique shock, but *subsonic* across the strong oblique shock.

17-95 Air flowing at a specified supersonic Mach number impinges on a two-dimensional wedge. The shock angle, Mach number, and pressure downstream of the weak and strong oblique shock formed by a wedge are to be determined.

Assumptions 1 The flow is steady. 2 The boundary layer on the wedge is very thin. 3 Air is an ideal gas with constant specific heats.

Properties The specific heat ratio of air is $k = 1.4$.

Analysis On the basis of Assumption #2, we take the deflection angle as equal to the wedge half-angle, i.e., $\theta \approx \delta = 8^\circ$. Then the two values of oblique shock angle β are determined from

$$\tan \theta = \frac{2(\text{Ma}_1^2 \sin^2 \beta - 1) / \tan \beta}{\text{Ma}_1^2 (k + \cos 2\beta) + 2} \rightarrow \tan 8^\circ = \frac{2(3.4^2 \sin^2 \beta - 1) / \tan \beta}{3.4^2 (1.4 + \cos 2\beta) + 2}$$

which is implicit in β . Therefore, we solve it by an iterative approach or with an equation solver such as EES. It gives $\beta_{\text{weak}} = 23.15^\circ$ and $\beta_{\text{strong}} = 87.45^\circ$. Then the upstream “normal” Mach number $\text{Ma}_{1,n}$ becomes

$$\text{Weak shock: } \text{Ma}_{1,n} = \text{Ma}_1 \sin \beta = 3.4 \sin 23.15^\circ = 1.336$$

$$\text{Strong shock: } \text{Ma}_{1,n} = \text{Ma}_1 \sin \beta = 3.4 \sin 87.45^\circ = 3.397$$

Also, the downstream normal Mach numbers $\text{Ma}_{2,n}$ become

$$\text{Weak shock: } \text{Ma}_{2,n} = \sqrt{\frac{(k-1)\text{Ma}_{1,n}^2 + 2}{2k\text{Ma}_{1,n}^2 - k + 1}} = \sqrt{\frac{(1.4-1)(1.336)^2 + 2}{2(1.4)(1.336)^2 - 1.4 + 1}} = 0.7681$$

$$\text{Strong shock: } \text{Ma}_{2,n} = \sqrt{\frac{(k-1)\text{Ma}_{1,n}^2 + 2}{2k\text{Ma}_{1,n}^2 - k + 1}} = \sqrt{\frac{(1.4-1)(3.397)^2 + 2}{2(1.4)(3.397)^2 - 1.4 + 1}} = 0.4553$$

The downstream pressure for each case is determined to be

$$\text{Weak shock: } P_2 = P_1 \frac{2k\text{Ma}_{1,n}^2 - k + 1}{k + 1} = (60 \text{ kPa}) \frac{2(1.4)(1.336)^2 - 1.4 + 1}{1.4 + 1} = \mathbf{115.0 \text{ kPa}}$$

$$\text{Strong shock: } P_2 = P_1 \frac{2k\text{Ma}_{1,n}^2 - k + 1}{k + 1} = (60 \text{ kPa}) \frac{2(1.4)(3.397)^2 - 1.4 + 1}{1.4 + 1} = \mathbf{797.6 \text{ kPa}}$$

The downstream Mach number is determined to be

$$\text{Weak shock: } \text{Ma}_2 = \frac{\text{Ma}_{2,n}}{\sin(\beta - \theta)} = \frac{0.7681}{\sin(23.15^\circ - 8^\circ)} = \mathbf{2.94}$$

$$\text{Strong shock: } \text{Ma}_2 = \frac{\text{Ma}_{2,n}}{\sin(\beta - \theta)} = \frac{0.4553}{\sin(87.45^\circ - 8^\circ)} = \mathbf{0.463}$$

Discussion Note that the change in Mach number and pressure across the *strong shock* are much greater than the changes across the *weak shock*, as expected. For both the weak and strong oblique shock cases, $\text{Ma}_{1,n}$ is supersonic and $\text{Ma}_{2,n}$ is subsonic. However, Ma_2 is *supersonic* across the weak oblique shock, but *subsonic* across the strong oblique shock.

17-96 Air flowing through a nozzle experiences a normal shock. The effect of the shock wave on various properties is to be determined. Analysis is to be repeated for helium under the same conditions.

Assumptions 1 Air and helium are ideal gases with constant specific heats. 2 Flow through the nozzle is steady, one-dimensional, and isentropic before the shock occurs.

Properties The properties of air are $k = 1.4$ and $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, and the properties of helium are $k = 1.667$ and $R = 2.0769 \text{ kJ/kg}\cdot\text{K}$.

Analysis The air properties upstream the shock are

$$\text{Ma}_1 = 2.6, P_1 = 58 \text{ kPa}, \text{ and } T_1 = 270 \text{ K}$$

Fluid properties after the shock (denoted by subscript 2) are related to those before the shock through the functions in Table A-33. For $\text{Ma}_1 = 2.6$,

$$\text{Ma}_2 = \mathbf{0.5039}, \frac{P_{02}}{P_1} = 9.1813, \frac{P_2}{P_1} = 7.7200, \text{ and } \frac{T_2}{T_1} = 2.2383$$

We obtained these values using analytical relations in Table 14. Then the stagnation pressure P_{02} , static pressure P_2 , and static temperature T_2 , are determined to be

$$P_{02} = 9.1813P_1 = (9.1813)(58 \text{ kPa}) = \mathbf{532.5 \text{ kPa}}$$

$$P_2 = 7.7200P_1 = (7.7200)(58 \text{ kPa}) = \mathbf{447.8 \text{ kPa}}$$

$$T_2 = 2.2383T_1 = (2.2383)(270 \text{ K}) = \mathbf{604.3 \text{ K}}$$

The air velocity after the shock can be determined from $V_2 = \text{Ma}_2 c_2$, where c_2 is the speed of sound at the exit conditions after the shock,

$$V_2 = \text{Ma}_2 c_2 = \text{Ma}_2 \sqrt{kRT_2} = (0.5039) \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(604.3 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = \mathbf{248.3 \text{ m/s}}$$

We now repeat the analysis for helium. This time we cannot use the tabulated values in Table A-33 since k is not 1.4. Therefore, we have to calculate the desired quantities using the analytical relations,

$$\text{Ma}_2 = \left(\frac{\text{Ma}_1^2 + 2/(k-1)}{2\text{Ma}_1^2 k/(k-1) - 1} \right)^{1/2} = \left(\frac{2.6^2 + 2/(1.667-1)}{2 \times 2.6^2 \times 1.667/(1.667-1) - 1} \right)^{1/2} = \mathbf{0.5455}$$

$$\frac{P_2}{P_1} = \frac{1 + k\text{Ma}_1^2}{1 + k\text{Ma}_2^2} = \frac{1 + 1.667 \times 2.6^2}{1 + 1.667 \times 0.5455^2} = 8.2009$$

$$\frac{T_2}{T_1} = \frac{1 + \text{Ma}_1^2(k-1)/2}{1 + \text{Ma}_2^2(k-1)/2} = \frac{1 + 2.6^2(1.667-1)/2}{1 + 0.5455^2(1.667-1)/2} = 2.9606$$

$$\begin{aligned} \frac{P_{02}}{P_1} &= \left(\frac{1 + k\text{Ma}_1^2}{1 + k\text{Ma}_2^2} \right) \left(1 + (k-1)\text{Ma}_2^2/2 \right)^{k/(k-1)} \\ &= \left(\frac{1 + 1.667 \times 2.6^2}{1 + 1.667 \times 0.5455^2} \right) \left(1 + (1.667-1) \times 0.5455^2/2 \right)^{1.667/0.667} = 10.389 \end{aligned}$$

Thus, $P_{02} = 10.389P_1 = (10.389)(58 \text{ kPa}) = \mathbf{602.5 \text{ kPa}}$

$$P_2 = 8.2009P_1 = (8.2009)(58 \text{ kPa}) = \mathbf{475.7 \text{ kPa}}$$

$$T_2 = 2.9606T_1 = (2.9606)(270 \text{ K}) = \mathbf{799.4 \text{ K}}$$

$$V_2 = \text{Ma}_2 c_2 = \text{Ma}_2 \sqrt{kRT_2} = (0.5455) \sqrt{(1.667)(2.0769 \text{ kJ/kg}\cdot\text{K})(799.4 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = \mathbf{907.5 \text{ m/s}}$$

Discussion The velocity and Mach number are higher for helium than for air due to the different values of k and R .

17-97 Air flowing through a nozzle experiences a normal shock. The entropy change of air across the normal shock wave is to be determined.

Assumptions 1 Air and helium are ideal gases with constant specific heats. 2 Flow through the nozzle is steady, one-dimensional, and isentropic before the shock occurs.

Properties The properties of air are $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ and $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, and the properties of helium are $R = 2.0769 \text{ kJ/kg}\cdot\text{K}$ and $c_p = 5.1926 \text{ kJ/kg}\cdot\text{K}$.

Analysis For air, the entropy change across the shock is determined to be

$$s_2 - s_1 = c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} = (1.005 \text{ kJ/kg}\cdot\text{K}) \ln(2.2383) - (0.287 \text{ kJ/kg}\cdot\text{K}) \ln(7.7200) = \mathbf{0.223 \text{ kJ/kg}\cdot\text{K}}$$

For helium, the entropy change across the shock is determined to be

$$s_2 - s_1 = c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} = (5.1926 \text{ kJ/kg}\cdot\text{K}) \ln(2.9606) - (2.0769 \text{ kJ/kg}\cdot\text{K}) \ln(8.2009) = \mathbf{1.27 \text{ kJ/kg}\cdot\text{K}}$$

Discussion Note that shock wave is a highly dissipative process, and the entropy generation is large during shock waves.

Duct Flow with Heat Transfer and Negligible Friction (Rayleigh Flow)

17-98C We are to discuss the effect of heating on the flow velocity in subsonic Rayleigh flow.

Analysis Heating the fluid **increases the flow velocity in subsonic Rayleigh flow, but decreases the flow velocity in supersonic Rayleigh flow.**

Discussion These results are not necessarily intuitive, but must be true in order to satisfy the conservation laws.

17-99C We are to discuss what the points on a T - s diagram of Rayleigh flow represent.

Analysis The points on the Rayleigh line represent the **states that satisfy the conservation of mass, momentum, and energy equations as well as the property relations for a given state.** Therefore, for a given inlet state, the fluid cannot exist at any downstream state outside the Rayleigh line on a T - s diagram.

Discussion The T - s diagram is quite useful, since any downstream state must lie on the Rayleigh line.

17-100C We are to discuss the effect of heat gain and heat loss on entropy during Rayleigh flow.

Analysis In Rayleigh flow, **the effect of heat gain is to increase the entropy of the fluid, and the effect of heat loss is to decrease the entropy.**

Discussion You should recall from thermodynamics that the entropy of a system can be lowered by removing heat.

17-101C We are to discuss how temperature and stagnation temperature change in subsonic Rayleigh flow.

Analysis In Rayleigh flow, the **stagnation temperature T_0 always increases with heat transfer to the fluid**, but the temperature T decreases with heat transfer in the Mach number range of $0.845 < Ma < 1$ for air. Therefore, the **temperature in this case will decrease**.

Discussion This at first seems counterintuitive, but if heat were *not* added, the temperature would drop even *more* if the air were accelerated isentropically from $Ma = 0.92$ to 0.95 .

17-102C We are to discuss the characteristic aspect of Rayleigh flow, and its main assumptions.

Analysis The characteristic aspect of Rayleigh flow is **its involvement of heat transfer**. The main assumptions associated with Rayleigh flow are: the flow is **steady, one-dimensional**, and **frictionless** through a constant-area duct, and the fluid is an **ideal gas with constant specific heats**.

Discussion Of course, there is no such thing as frictionless flow. It is better to say that frictional effects are negligible compared to the heating effects.

17-103C We are to examine the Mach number at the end of a choked duct in Rayleigh flow when more heat is added.

Analysis The flow is choked, and thus the flow at the duct exit **remains sonic**.

Discussion There is no mechanism for the flow to become supersonic in this case.

17-104 Argon flowing at subsonic velocity in a constant-diameter duct is accelerated by heating. The highest rate of heat transfer without reducing the mass flow rate is to be determined.

Assumptions 1 The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid. 2 Mass flow rate remains constant.

Properties We take the properties of argon to be $k = 1.667$, $c_p = 0.5203 \text{ kJ/kg}\cdot\text{K}$, and $R = 0.2081 \text{ kJ/kg}\cdot\text{K}$.

Analysis Heat transfer stops when the flow is choked, and thus $\text{Ma}_2 = V_2/c_2 = 1$. The inlet stagnation temperature is

$$T_{01} = T_1 \left(1 + \frac{k-1}{2} \text{Ma}_1^2 \right) = (400 \text{ K}) \left(1 + \frac{1.667-1}{2} 0.2^2 \right) = 405.3 \text{ K}$$

The Rayleigh flow functions corresponding to the inlet and exit Mach numbers are

$$T_{02}/T_0^* = 1 \quad (\text{since } \text{Ma}_2 = 1)$$

$$\frac{T_{01}}{T_0^*} = \frac{(k+1)\text{Ma}_1^2 [2 + (k-1)\text{Ma}_1^2]}{(1+k\text{Ma}_1^2)^2} = \frac{(1.667+1)0.2^2 [2 + (1.667-1)0.2^2]}{(1+1.667 \times 0.2^2)^2} = 0.1900$$

Therefore,

$$\frac{T_{02}}{T_{01}} = \frac{T_{02}/T_0^*}{T_{01}/T_0^*} = \frac{1}{0.1900} \quad \rightarrow \quad T_{02} = T_{01} / 0.1900 = (405.3 \text{ K}) / 0.1900 = 2133 \text{ K}$$

Then the rate of heat transfer becomes

$$\dot{Q} = \dot{m}_{\text{air}} c_p (T_{02} - T_{01}) = (1.2 \text{ kg/s})(0.5203 \text{ kJ/kg}\cdot\text{K})(2133 - 400) \text{ K} = \mathbf{1080 \text{ kW}}$$

Discussion It can also be shown that $T_2 = 1600 \text{ K}$, which is the highest thermodynamic temperature that can be attained under stated conditions. If more heat is transferred, the additional temperature rise will cause the mass flow rate to decrease. Also, in the solution of this problem, we cannot use the values of Table A-34 since they are based on $k = 1.4$.

17-105 Air is heated in a duct during subsonic flow until it is choked. For specified pressure and velocity at the exit, the temperature, pressure, and velocity at the inlet are to be determined.

Assumptions The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid.

Properties We take the properties of air to be $k = 1.4$, $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, and $R = 0.287 \text{ kJ/kg}\cdot\text{K}$.

Analysis Noting that sonic conditions exist at the exit, the exit temperature is

$$c_2 = V_2/\text{Ma}_2 = (680 \text{ m/s})/1 = 680 \text{ m/s}$$

$$c_2 = \sqrt{kRT_2} \rightarrow \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})T_2 \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 680 \text{ m/s}$$

It gives

$$T_2 = 1151 \text{ K.}$$

Then the exit stagnation temperature becomes

$$T_{02} = T_2 + \frac{V_2^2}{2c_p} = 1151 \text{ K} + \frac{(680 \text{ m/s})^2}{2 \times 1.005 \text{ kJ/kg}\cdot\text{K}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 1381 \text{ K}$$

The inlet stagnation temperature is, from the energy equation $q = c_p(T_{02} - T_{01})$,

$$T_{01} = T_{02} - \frac{q}{c_p} = 1381 \text{ K} - \frac{67 \text{ kJ/kg}}{1.005 \text{ kJ/kg}\cdot\text{K}} = 1314 \text{ K}$$

The maximum value of stagnation temperature T_0^* occurs at $\text{Ma} = 1$, and its value in this case is T_{02} since the flow is choked. Therefore, $T_0^* = T_{02} = 1381 \text{ K}$. Then the stagnation temperature ratio at the inlet, and the Mach number corresponding to it are, from Table A-34,

$$\frac{T_{01}}{T_0^*} = \frac{1314 \text{ K}}{1381 \text{ K}} = 0.9516 \rightarrow \text{Ma}_1 = 0.7779 \cong \mathbf{0.778}$$

The Rayleigh flow functions corresponding to the inlet and exit Mach numbers are (Table A-34):

$$\begin{array}{llll} \text{Ma}_1 = 0.7779: & T_1/T^* = 1.018, & P_1/P^* = 1.301, & V_1/V^* = 0.7852 \\ \text{Ma}_2 = 1: & T_2/T^* = 1, & P_2/P^* = 1, & V_2/V^* = 1 \end{array}$$

Then the inlet temperature, pressure, and velocity are determined to be

$$\frac{T_2}{T_1} = \frac{T_2/T^*}{T_1/T^*} = \frac{1}{1.018} \rightarrow T_1 = 1.018T_2 = 1.018(1151 \text{ K}) = \mathbf{1172 \text{ K}}$$

$$\frac{P_2}{P_1} = \frac{P_2/P^*}{P_1/P^*} = \frac{1}{1.301} \rightarrow P_1 = 1.301P_2 = 1.301(270 \text{ kPa}) = \mathbf{351.3 \text{ kPa}}$$

$$\frac{V_2}{V_1} = \frac{V_2/V^*}{V_1/V^*} = \frac{1}{0.7852} \rightarrow V_1 = 0.7852V_2 = 0.7852(680 \text{ m/s}) = \mathbf{533.9 \text{ m/s}}$$

Discussion Note that the temperature and pressure decreases with heating during this subsonic Rayleigh flow while velocity increases. This problem can also be solved using appropriate relations instead of tabulated values, which can likewise be coded for convenient computer solutions.

17-106 Air enters the combustion chamber of a gas turbine at a subsonic velocity. For a specified rate of heat transfer, the Mach number at the exit and the loss in stagnation pressure to be determined.

Assumptions 1 The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid. 2 The cross-sectional area of the combustion chamber is constant. 3 The increase in mass flow rate due to fuel injection is disregarded.

Properties We take the properties of air to be $k = 1.4$, $c_p = 1.005$ kJ/kg·K, and $R = 0.287$ kJ/kg·K.

Analysis The inlet stagnation temperature and pressure are

$$T_{01} = T_1 \left(1 + \frac{k-1}{2} \text{Ma}_1^2 \right) = (700 \text{ K}) \left(1 + \frac{1.4-1}{2} 0.2^2 \right) = 705.6 \text{ K}$$

$$P_{01} = P_1 \left(1 + \frac{k-1}{2} \text{Ma}_1^2 \right)^{k/(k-1)} = (600 \text{ kPa}) \left(1 + \frac{1.4-1}{2} 0.2^2 \right)^{1.4/0.4} = 617.0 \text{ kPa}$$

The exit stagnation temperature is determined from

$$\dot{Q} = \dot{m}_{\text{air}} c_p (T_{02} - T_{01}) \rightarrow 150 \text{ kJ/s} = (0.3 \text{ kg/s})(1.005 \text{ kJ/kg} \cdot \text{K})(T_{02} - 705.6 \text{ K})$$

It gives

$$T_{02} = 1203 \text{ K}$$

At $\text{Ma}_1 = 0.2$ we read from $T_{01}/T_0^* = 0.1736$ (Table A-34). Therefore,

$$T_0^* = \frac{T_{01}}{0.1736} = \frac{705.6 \text{ K}}{0.1736} = 4064.5 \text{ K}$$

Then the stagnation temperature ratio at the exit and the Mach number corresponding to it are (Table A-34)

$$\frac{T_{02}}{T_0^*} = \frac{1203 \text{ K}}{4064.5 \text{ K}} = 0.2960 \rightarrow \text{Ma}_2 = 0.2706 \cong \mathbf{0.271}$$

Also,

$$\text{Ma}_1 = 0.2 \rightarrow P_{01}/P_0^* = 1.2346$$

$$\text{Ma}_2 = 0.2706 \rightarrow P_{02}/P_0^* = 1.2091$$

Then the stagnation pressure at the exit and the pressure drop become

$$\frac{P_{02}}{P_{01}} = \frac{P_{02}/P_0^*}{P_{01}/P_0^*} = \frac{1.2091}{1.2346} = 0.9794 \rightarrow P_{02} = 0.9794 P_{01} = 0.9794(617 \text{ kPa}) = 604.3 \text{ kPa}$$

and

$$\Delta P_0 = P_{01} - P_{02} = 617.0 - 604.3 = \mathbf{12.7 \text{ kPa}}$$

Discussion This problem can also be solved using appropriate relations instead of tabulated values, which can likewise be coded for convenient computer solutions.

17-107 Air enters the combustion chamber of a gas turbine at a subsonic velocity. For a specified rate of heat transfer, the Mach number at the exit and the loss in stagnation pressure to be determined.

Assumptions 1 The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid. 2 The cross-sectional area of the combustion chamber is constant. 3 The increase in mass flow rate due to fuel injection is disregarded.

Properties We take the properties of air to be $k = 1.4$, $c_p = 1.005$ kJ/kg·K, and $R = 0.287$ kJ/kg·K.

Analysis The inlet stagnation temperature and pressure are

$$T_{01} = T_1 \left(1 + \frac{k-1}{2} \text{Ma}_1^2 \right) = (700 \text{ K}) \left(1 + \frac{1.4-1}{2} 0.2^2 \right) = 705.6 \text{ K}$$

$$P_{01} = P_1 \left(1 + \frac{k-1}{2} \text{Ma}_1^2 \right)^{k/(k-1)} = (600 \text{ kPa}) \left(1 + \frac{1.4-1}{2} 0.2^2 \right)^{1.4/0.4} = 617.0 \text{ kPa}$$

The exit stagnation temperature is determined from

$$\dot{Q} = \dot{m}_{\text{air}} c_p (T_{02} - T_{01}) \rightarrow 300 \text{ kJ/s} = (0.3 \text{ kg/s})(1.005 \text{ kJ/kg} \cdot \text{K})(T_{02} - 705.6 \text{ K})$$

It gives

$$T_{02} = 1701 \text{ K}$$

At $\text{Ma}_1 = 0.2$ we read from $T_{01}/T_0^* = 0.1736$ (Table A-34). Therefore,

$$T_0^* = \frac{T_{01}}{0.1736} = \frac{705.6 \text{ K}}{0.1736} = 4064.5 \text{ K}$$

Then the stagnation temperature ratio at the exit and the Mach number corresponding to it are (Table A-34)

$$\frac{T_{02}}{T_0^*} = \frac{1701 \text{ K}}{4064.5 \text{ K}} = 0.4185 \rightarrow \text{Ma}_2 = 0.3393 \cong \mathbf{0.339}$$

Also,

$$\text{Ma}_1 = 0.2 \rightarrow P_{01}/P_0^* = 1.2346$$

$$\text{Ma}_2 = 0.3393 \rightarrow P_{02}/P_0^* = 1.1820$$

Then the stagnation pressure at the exit and the pressure drop become

$$\frac{P_{02}}{P_{01}} = \frac{P_{02}/P_0^*}{P_{01}/P_0^*} = \frac{1.1820}{1.2346} = 0.9574 \rightarrow P_{02} = 0.9574 P_{01} = 0.9574(617 \text{ kPa}) = 590.7 \text{ kPa}$$

and

$$\Delta P_0 = P_{01} - P_{02} = 617.0 - 590.7 = \mathbf{26.3 \text{ kPa}}$$

Discussion This problem can also be solved using appropriate relations instead of tabulated values, which can likewise be coded for convenient computer solutions.

17-108E Air flowing with a subsonic velocity in a round duct is accelerated by heating until the flow is choked at the exit. The rate of heat transfer and the pressure drop are to be determined.

Assumptions 1 The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid. 2 The flow is choked at the duct exit. 3 Mass flow rate remains constant.

Properties We take the properties of air to be $k = 1.4$, $c_p = 0.2400$ Btu/lbm·R, and $R = 0.06855$ Btu/lbm·R = 0.3704 psia·ft³/lbm·R.

Analysis The inlet density and velocity of air are

$$\rho_1 = \frac{P_1}{RT_1} = \frac{30 \text{ psia}}{(0.3704 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(800 \text{ R})} = 0.1012 \text{ lbm/ft}^3$$

$$V_1 = \frac{\dot{m}_{\text{air}}}{\rho_1 A_{c1}} = \frac{5 \text{ lbm/s}}{(0.1012 \text{ lbm/ft}^3)[\pi(4/12 \text{ ft})^2/4]} = 565.9 \text{ ft/s}$$

The stagnation temperature and Mach number at the inlet are

$$T_{01} = T_1 + \frac{V_1^2}{2c_p} = 800 \text{ R} + \frac{(565.9 \text{ ft/s})^2}{2 \times 0.2400 \text{ Btu/lbm} \cdot \text{R}} \left(\frac{1 \text{ Btu/lbm}}{25,037 \text{ ft}^2/\text{s}^2} \right) = 826.7 \text{ R}$$

$$c_1 = \sqrt{kRT_1} = \sqrt{(1.4)(0.06855 \text{ Btu/lbm} \cdot \text{R})(800 \text{ R})} \left(\frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right) = 1386 \text{ ft/s}$$

$$\text{Ma}_1 = \frac{V_1}{c_1} = \frac{565.9 \text{ ft/s}}{1386 \text{ ft/s}} = 0.4082$$

The Rayleigh flow functions corresponding to the inlet and exit Mach numbers are (Table A-34):

$$\text{Ma}_1 = 0.4082: \quad T_1/T^* = 0.6310, \quad P_1/P^* = 1.946, \quad T_{01}/T_0^* = 0.5434$$

$$\text{Ma}_2 = 1: \quad T_2/T^* = 1, \quad P_2/P^* = 1, \quad T_{02}/T_0^* = 1$$

Then the exit temperature, pressure, and stagnation temperature are determined to be

$$\frac{T_2}{T_1} = \frac{T_2/T^*}{T_1/T^*} = \frac{1}{0.6310} \quad \rightarrow \quad T_2 = T_1 / 0.6310 = (800 \text{ R}) / 0.6310 = 1268 \text{ R}$$

$$\frac{P_2}{P_1} = \frac{P_2/P^*}{P_1/P^*} = \frac{1}{1.946} \quad \rightarrow \quad P_2 = P_1 / 1.946 = (30 \text{ psia}) / 1.946 = 15.4 \text{ psia}$$

$$\frac{T_{02}}{T_{01}} = \frac{T_{02}/T_0^*}{T_{01}/T_0^*} = \frac{1}{0.5434} \quad \rightarrow \quad T_{02} = T_{01} / 0.5434 = (826.7 \text{ R}) / 0.5434 = 1521 \text{ R}$$

Then the rate of heat transfer and the pressure drop become

$$\dot{Q} = \dot{m}_{\text{air}} c_p (T_{02} - T_{01}) = (5 \text{ lbm/s})(0.2400 \text{ Btu/lbm} \cdot \text{R})(1521 - 826.7) \text{ R} = \mathbf{834 \text{ Btu/s}}$$

$$\Delta P = P_1 - P_2 = 30 - 15.4 = \mathbf{14.6 \text{ psia}}$$

Discussion Note that the entropy of air increases during this heating process, as expected.

17-109 Air flowing with a subsonic velocity in a duct. The variation of entropy with temperature is to be investigated as the exit temperature varies from 600 K to 5000 K in increments of 200 K. The results are to be tabulated and plotted.

Analysis We solve this problem using EES making use of Rayleigh functions. The EES *Equations* window is printed below, along with the tabulated and plotted results.

Discussion Note that the entropy of air increases during this heating process, as expected.

17-110E Air flowing with a subsonic velocity in a square duct is accelerated by heating until the flow is choked at the exit. The rate of heat transfer and the entropy change are to be determined.

Assumptions 1 The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid. 2 The flow is choked at the duct exit. 3 Mass flow rate remains constant.

Properties We take the properties of air to be $k = 1.4$, $c_p = 0.2400$ Btu/lbm·R, and $R = 0.06855$ Btu/lbm·R = 0.3704 psia·ft³/lbm·R.

Analysis The inlet density and mass flow rate of air are

$$\rho_1 = \frac{P_1}{RT_1} = \frac{80 \text{ psia}}{(0.3704 \text{ psia} \cdot \text{ft}^3/\text{lbm} \cdot \text{R})(700 \text{ R})} = 0.3085 \text{ lbm/ft}^3$$

$$\dot{m}_{\text{air}} = \rho_1 A_{c1} V_1 = (0.3085 \text{ lbm/ft}^3)(6 \times 6/144 \text{ ft}^2)(260 \text{ ft/s}) = 20.06 \text{ lbm/s}$$

The stagnation temperature and Mach number at the inlet are

$$T_{01} = T_1 + \frac{V_1^2}{2c_p} = 700 \text{ R} + \frac{(260 \text{ ft/s})^2}{2 \times 0.2400 \text{ Btu/lbm} \cdot \text{R}} \left(\frac{1 \text{ Btu/lbm}}{25,037 \text{ ft}^2/\text{s}^2} \right) = 705.6 \text{ R}$$

$$c_1 = \sqrt{kRT_1} = \sqrt{(1.4)(0.06855 \text{ Btu/lbm} \cdot \text{R})(700 \text{ R})} \left(\frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right) = 1297 \text{ ft/s}$$

$$\text{Ma}_1 = \frac{V_1}{c_1} = \frac{260 \text{ ft/s}}{1297 \text{ ft/s}} = 0.2005$$

The Rayleigh flow functions corresponding to the inlet and exit Mach numbers are (Table A-34):

$$\text{Ma}_1 = 0.2005: \quad T_1/T^* = 0.2075, \quad P_1/P^* = 2.272, \quad T_{01}/T_0^* = 0.1743$$

$$\text{Ma}_2 = 1: \quad T_2/T^* = 1, \quad P_2/P^* = 1, \quad T_{02}/T_0^* = 1$$

Then the exit temperature, pressure, and stagnation temperature are determined to be

$$\frac{T_2}{T_1} = \frac{T_2/T^*}{T_1/T^*} = \frac{1}{0.2075} \quad \rightarrow \quad T_2 = T_1 / 0.2075 = (700 \text{ R}) / 0.2075 = 3374 \text{ R}$$

$$\frac{P_2}{P_1} = \frac{P_2/P^*}{P_1/P^*} = \frac{1}{2.272} \quad \rightarrow \quad P_2 = P_1 / 2.272 = (80 \text{ psia}) / 2.272 = 35.2 \text{ psia}$$

$$\frac{T_{02}}{T_{01}} = \frac{T_{02}/T_0^*}{T_{01}/T_0^*} = \frac{1}{0.1743} \quad \rightarrow \quad T_{02} = T_{01} / 0.1743 = (705.6 \text{ R}) / 0.1743 = 4048 \text{ R}$$

Then the rate of heat transfer and entropy change become

$$\dot{Q} = \dot{m}_{\text{air}} c_p (T_{02} - T_{01}) = (20.06 \text{ lbm/s})(0.2400 \text{ Btu/lbm} \cdot \text{R})(4048 - 705.6) \text{ R} = \mathbf{16,090 \text{ Btu/s}}$$

$$\Delta s = c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1} = (0.2400 \text{ Btu/lbm} \cdot \text{R}) \ln \frac{3374 \text{ R}}{700 \text{ R}} - (0.06855 \text{ Btu/lbm} \cdot \text{R}) \ln \frac{35.2 \text{ psia}}{80 \text{ psia}} = \mathbf{0.434 \text{ Btu/lbm} \cdot \text{R}}$$

Discussion Note that the entropy of air increases during this heating process, as expected.

17-111 Fuel is burned in a rectangular duct with compressed air. For specified heat transfer, the exit temperature and Mach number are to be determined.

Assumptions The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid.

Properties We take the properties of air to be $k = 1.4$, $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, and $R = 0.287 \text{ kJ/kg}\cdot\text{K}$.

Analysis The stagnation temperature and Mach number at the inlet are

$$c_1 = \sqrt{kRT_1} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(300 \text{ K})\left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}}\right)} = 347.2 \text{ m/s}$$

$$V_1 = \text{Ma}_1 c_1 = 2(347.2 \text{ m/s}) = 694.4 \text{ m/s}$$

$$T_{01} = T_1 + \frac{V_1^2}{2c_p} = 300 \text{ K} + \frac{(694.4 \text{ m/s})^2}{2 \times 1.005 \text{ kJ/kg}\cdot\text{K}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2}\right) = 539.9 \text{ K}$$

The exit stagnation temperature is, from the energy equation $q = c_p(T_{02} - T_{01})$,

$$T_{02} = T_{01} + \frac{q}{c_p} = 539.9 \text{ K} + \frac{55 \text{ kJ/kg}}{1.005 \text{ kJ/kg}\cdot\text{K}} = 594.6 \text{ K}$$

The maximum value of stagnation temperature T_0^* occurs at $\text{Ma} = 1$, and its value can be determined from Table A-34 or from the appropriate relation. At $\text{Ma}_1 = 2$ we read $T_{01}/T_0^* = 0.7934$. Therefore,

$$T_0^* = \frac{T_{01}}{0.7934} = \frac{539.9 \text{ K}}{0.7934} = 680.5 \text{ K}$$

The stagnation temperature ratio at the exit and the Mach number corresponding to it are, from Table A-34,

$$\frac{T_{02}}{T_0^*} = \frac{594.6 \text{ K}}{680.5 \text{ K}} = 0.8738 \quad \rightarrow \quad \text{Ma}_2 = 1.642 \cong \mathbf{1.64}$$

Also,

$$\text{Ma}_1 = 2 \quad \rightarrow \quad T_1/T^* = 0.5289$$

$$\text{Ma}_2 = 1.642 \quad \rightarrow \quad T_2/T^* = 0.6812$$

Then the exit temperature becomes

$$\frac{T_2}{T_1} = \frac{T_2/T^*}{T_1/T^*} = \frac{0.6812}{0.5289} = 1.288 \quad \rightarrow \quad T_2 = 1.288T_1 = 1.288(300 \text{ K}) = \mathbf{386 \text{ K}}$$

Discussion Note that the temperature increases during this supersonic Rayleigh flow with heating. This problem can also be solved using appropriate relations instead of tabulated values, which can likewise be coded for convenient computer solutions.

17-112 Compressed air is cooled as it flows in a rectangular duct. For specified heat rejection, the exit temperature and Mach number are to be determined.

Assumptions The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid.

Properties We take the properties of air to be $k = 1.4$, $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, and $R = 0.287 \text{ kJ/kg}\cdot\text{K}$.

Analysis The stagnation temperature and Mach number at the inlet are

$$c_1 = \sqrt{kRT_1} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(300 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 347.2 \text{ m/s}$$

$$V_1 = \text{Ma}_1 c_1 = 2(347.2 \text{ m/s}) = 694.4 \text{ m/s}$$

$$T_{01} = T_1 + \frac{V_1^2}{2c_p} = 300 \text{ K} + \frac{(694.4 \text{ m/s})^2}{2 \times 1.005 \text{ kJ/kg}\cdot\text{K}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 539.9 \text{ K}$$

The exit stagnation temperature is, from the energy equation $q = c_p(T_{02} - T_{01})$,

$$T_{02} = T_{01} + \frac{q}{c_p} = 539.9 \text{ K} + \frac{-55 \text{ kJ/kg}}{1.005 \text{ kJ/kg}\cdot\text{K}} = 485.2 \text{ K}$$

The maximum value of stagnation temperature T_0^* occurs at $\text{Ma} = 1$, and its value can be determined from Table A-34 or from the appropriate relation. At $\text{Ma}_1 = 2$ we read $T_{01}/T_0^* = 0.7934$. Therefore,

$$T_0^* = \frac{T_{01}}{0.7934} = \frac{539.9 \text{ K}}{0.7934} = 680.5 \text{ K}$$

The stagnation temperature ratio at the exit and the Mach number corresponding to it are, from Table A-34,

$$\frac{T_{02}}{T_0^*} = \frac{485.2 \text{ K}}{680.5 \text{ K}} = 0.7130 \quad \rightarrow \quad \text{Ma}_2 = 2.479 \cong \mathbf{2.48}$$

Also,

$$\text{Ma}_1 = 2 \quad \rightarrow \quad T_1/T^* = 0.5289$$

$$\text{Ma}_2 = 2.479 \quad \rightarrow \quad T_2/T^* = 0.3838$$

Then the exit temperature becomes

$$\frac{T_2}{T_1} = \frac{T_2/T^*}{T_1/T^*} = \frac{0.3838}{0.5289} = 0.7257 \quad \rightarrow \quad T_2 = 0.7257 T_1 = 0.7257(300 \text{ K}) = \mathbf{218 \text{ K}}$$

Discussion Note that the temperature decreases and Mach number increases during this supersonic Rayleigh flow with cooling. This problem can also be solved using appropriate relations instead of tabulated values, which can likewise be coded for convenient computer solutions.

17-113 Fuel is burned in a tubular combustion chamber with compressed air. For a specified exit Mach number, the exit temperature and the rate of fuel consumption are to be determined.

Assumptions 1 The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid. 2 Combustion is complete, and it is treated as a heat addition process, with no change in the chemical composition of flow. 3 The increase in mass flow rate due to fuel injection is disregarded.

Properties We take the properties of air to be $k = 1.4$, $c_p = 1.005$ kJ/kg·K, and $R = 0.287$ kJ/kg·K.

Analysis The inlet density and mass flow rate of air are

$$\rho_1 = \frac{P_1}{RT_1} = \frac{380 \text{ kPa}}{(0.287 \text{ kJ/kg}\cdot\text{K})(450 \text{ K})} = 2.942 \text{ kg/m}^3$$

$$\dot{m}_{\text{air}} = \rho_1 A_{c1} V_1 = (2.942 \text{ kg/m}^3) [\pi(0.16 \text{ m})^2 / 4] (55 \text{ m/s}) = 3.254 \text{ kg/s}$$

The stagnation temperature and Mach number at the inlet are

$$T_{01} = T_1 + \frac{V_1^2}{2c_p} = 450 \text{ K} + \frac{(55 \text{ m/s})^2}{2 \times 1.005 \text{ kJ/kg}\cdot\text{K}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 451.5 \text{ K}$$

$$c_1 = \sqrt{kRT_1} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(450 \text{ K})} \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right) = 425.2 \text{ m/s}$$

$$\text{Ma}_1 = \frac{V_1}{c_1} = \frac{55 \text{ m/s}}{425.2 \text{ m/s}} = 0.1293$$

The Rayleigh flow functions corresponding to the inlet and exit Mach numbers are (Table A-34) (We used analytical functions):

$$\text{Ma}_1 = 0.1293: \quad T_1/T^* = 0.09201, \quad T_{01}/T^* = 0.07693, \quad V_1/V^* = 0.03923$$

$$\text{Ma}_2 = 0.8: \quad T_2/T^* = 1.0255, \quad T_{02}/T^* = 0.9639, \quad V_2/V^* = 0.8101$$

The exit temperature, stagnation temperature, and velocity are determined to be

$$\frac{T_2}{T_1} = \frac{T_2/T^*}{T_1/T^*} = \frac{1.0255}{0.09201} = 11.146 \rightarrow T_2 = 11.146 T_1 = 11.146(450 \text{ K}) = \mathbf{5016 \text{ K}}$$

$$\frac{T_{02}}{T_{01}} = \frac{T_{02}/T^*}{T_{01}/T^*} = \frac{0.9639}{0.07693} = 12.530 \rightarrow T_{02} = 12.530 T_{01} = 12.530(451.5 \text{ K}) = 5658 \text{ K}$$

$$\frac{V_2}{V_1} = \frac{V_2/V^*}{V_1/V^*} = \frac{0.8101}{0.03923} = 20.650 \rightarrow V_2 = 20.650 V_1 = 20.650(55 \text{ m/s}) = 1136 \text{ m/s}$$

Then the mass flow rate of the fuel is determined to be

$$q = c_p (T_{02} - T_{01}) = (1.005 \text{ kJ/kg}\cdot\text{K})(5658 - 451.5) \text{ K} = 5232 \text{ kJ/kg}$$

$$\dot{Q} = \dot{m}_{\text{air}} q = (3.254 \text{ kg/s})(5232 \text{ kJ/kg}) = 17,024 \text{ kW}$$

$$\dot{m}_{\text{fuel}} = \frac{\dot{Q}}{HV} = \frac{17,024 \text{ kJ/s}}{39,000 \text{ kJ/kg}} = \mathbf{0.4365 \text{ kg/s}}$$

Discussion Note that both the temperature and velocity increase during this subsonic Rayleigh flow with heating, as expected. This problem can also be solved using appropriate relations instead of tabulated values, which can likewise be coded for convenient computer solutions.

17-114 Air flowing at a supersonic velocity in a duct is decelerated by heating. The highest temperature air can be heated by heat addition and the rate of heat transfer are to be determined.

Assumptions 1 The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid. 2 Mass flow rate remains constant.

Properties We take the properties of air to be $k = 1.4$, $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, and $R = 0.287 \text{ kJ/kg}\cdot\text{K}$.

Analysis Heat transfer will stop when the flow is choked, and thus $\text{Ma}_2 = V_2/c_2 = 1$. Knowing stagnation properties, the static properties are determined to be

$$T_1 = T_{01} \left(1 + \frac{k-1}{2} \text{Ma}_1^2 \right)^{-1} = (600 \text{ K}) \left(1 + \frac{1.4-1}{2} 1.8^2 \right)^{-1} = 364.1 \text{ K}$$

$$P_1 = P_{01} \left(1 + \frac{k-1}{2} \text{Ma}_1^2 \right)^{-k/(k-1)} = (140 \text{ kPa}) \left(1 + \frac{1.4-1}{2} 1.8^2 \right)^{-1.4/0.4} \\ = 24.37 \text{ kPa}$$

$$\rho_1 = \frac{P_1}{RT_1} = \frac{24.37 \text{ kPa}}{(0.287 \text{ kJ/kg}\cdot\text{K})(364.1 \text{ K})} = 0.2332 \text{ kg/m}^3$$

Then the inlet velocity and the mass flow rate become

$$c_1 = \sqrt{kRT_1} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(364.1 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 382.5 \text{ m/s}$$

$$V_1 = \text{Ma}_1 c_1 = 1.8(382.5 \text{ m/s}) = 688.5 \text{ m/s}$$

$$\dot{m}_{air} = \rho_1 A_{c1} V_1 = (0.2332 \text{ kg/m}^3) [\pi(0.07 \text{ m})^2 / 4] (688.5 \text{ m/s}) = 0.6179 \text{ kg/s}$$

The Rayleigh flow functions corresponding to the inlet and exit Mach numbers are (Table A-34):

$$\text{Ma}_1 = 1.8: \quad T_1/T^* = 0.6089, \quad T_{01}/T_0^* = 0.8363$$

$$\text{Ma}_2 = 1: \quad T_2/T^* = 1, \quad T_{02}/T_0^* = 1$$

Then the exit temperature and stagnation temperature are determined to be

$$\frac{T_2}{T_1} = \frac{T_2/T^*}{T_1/T^*} = \frac{1}{0.6089} \quad \rightarrow \quad T_2 = T_1 / 0.6089 = (364.1 \text{ K}) / 0.6089 = \mathbf{598 \text{ K}}$$

$$\frac{T_{02}}{T_{01}} = \frac{T_{02}/T_0^*}{T_{01}/T_0^*} = \frac{1}{0.8363} \quad \rightarrow \quad T_{02} = T_{01} / 0.8363 = (600 \text{ K}) / 0.8363 = 717.4 \text{ K} \cong \mathbf{717 \text{ K}}$$

Finally, the rate of heat transfer is

$$\dot{Q} = \dot{m}_{air} c_p (T_{02} - T_{01}) = (0.6179 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(717.4 - 600) \text{ K} = \mathbf{72.9 \text{ kW}}$$

Discussion Note that this is the highest temperature that can be attained under stated conditions. If more heat is transferred, the additional temperature will cause the mass flow rate to decrease. Also, once the sonic conditions are reached, the thermodynamic temperature can be increased further by cooling the fluid and reducing the velocity (see the T - s diagram for Rayleigh flow).

Steam Nozzles

17-115C The delay in the condensation of the steam is called supersaturation. It occurs in high-speed flows where there isn't sufficient time for the necessary heat transfer and the formation of liquid droplets.

17-116 Steam enters a converging nozzle with a low velocity. The exit velocity, mass flow rate, and exit Mach number are to be determined for isentropic and 94 percent efficient nozzle cases.

Assumptions 1 Flow through the nozzle is steady and one-dimensional. **2** The nozzle is adiabatic.

Analysis (a) The inlet stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible. Thus $h_{01} = h_1$.

At the inlet,

$$\left. \begin{aligned} P_1 = P_{01} = 5 \text{ MPa} \\ T_1 = T_{01} = 400^\circ\text{C} \end{aligned} \right\} \begin{aligned} h_1 = h_{01} = 3196.7 \text{ kJ/kg} \\ s_1 = s_{2s} = 6.6483 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

At the exit,

$$\left. \begin{aligned} P_2 = 3 \text{ MPa} \\ s_2 = 6.6483 \text{ kJ/kg} \cdot \text{K} \end{aligned} \right\} \begin{aligned} h_2 = 3057.0 \text{ kJ/kg} \\ v_2 = 0.08601 \text{ m}^3/\text{kg} \end{aligned}$$

- a) $\eta_N = 100\%$
b) $\eta_N = 94\%$

Then the exit velocity is determined from the steady-flow energy balance $\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$ with $q = w = 0$,

$$h_1 + V_1^2/2 = h_2 + V_2^2/2 \longrightarrow 0 = h_2 - h_1 + \frac{V_2^2 - V_1^2}{2}$$

Solving for V_2 ,

$$V_2 = \sqrt{2(h_1 - h_2)} = \sqrt{2(3196.7 - 3057.0) \text{ kJ/kg} \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = \mathbf{528.5 \text{ m/s}}$$

The mass flow rate is determined from

$$\dot{m} = \frac{1}{v_2} A_2 V_2 = \frac{1}{0.08601 \text{ m}^3/\text{kg}} (60 \times 10^{-4} \text{ m}^2)(528.5 \text{ m/s}) = \mathbf{36.86 \text{ kg/s}}$$

The velocity of sound at the exit of the nozzle is determined from

$$c = \left(\frac{\partial \mathcal{P}}{\partial \rho} \right)_s \cong \left(\frac{\Delta \mathcal{P}}{\Delta(1/v)} \right)_s$$

The specific volume of steam at $s_2 = 6.6483 \text{ kJ/kg} \cdot \text{K}$ and at pressures just below and just above the specified pressure (2.5 and 3.5 MPa) are determined to be 0.09906 and 0.07632 m^3/kg . Substituting,

$$c_2 = \sqrt{\frac{(3500 - 2500) \text{ kPa}}{\left(\frac{1}{0.07632} - \frac{1}{0.09906} \right) \text{ kg/m}^3} \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kPa} \cdot \text{m}^3} \right)} = 576.6 \text{ m/s}$$

Then the exit Mach number becomes

$$\text{Ma}_2 = \frac{V_2}{c_2} = \frac{528.5 \text{ m/s}}{576.6 \text{ m/s}} = \mathbf{0.917}$$

(b) The inlet stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible. Thus $h_{01} = h_1$.

At the inlet,

$$\left. \begin{aligned} P_1 = P_{01} = 5 \text{ MPa} \\ T_1 = T_{01} = 400^\circ\text{C} \end{aligned} \right\} \begin{aligned} h_1 = h_{01} = 3196.7 \text{ kJ/kg} \\ s_1 = s_{2s} = 6.6483 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

At state 2s,

$$\left. \begin{array}{l} P_{2s} = 3 \text{ MPa} \\ s_{2s} = 6.6483 \text{ kJ/kg} \cdot \text{K} \end{array} \right\} h_{2s} = 3057.0 \text{ kJ/kg}$$

The enthalpy of steam at the actual exit state is determined from

$$\eta_N = \frac{h_{01} - h_2}{h_{01} - h_{2s}} \longrightarrow 0.94 = \frac{3196.7 - h_2}{3196.7 - 3057.0} \longrightarrow h_2 = 3065.4 \text{ kJ/kg}$$

Therefore,

$$\left. \begin{array}{l} P_2 = 3 \text{ MPa} \\ h_2 = 3065.4 \text{ kJ/kg} \end{array} \right\} \begin{array}{l} v_2 = 0.08666 \text{ m}^3/\text{kg} \\ s_2 = 6.6622 \text{ kJ/kg} \cdot \text{K} \end{array}$$

Then the exit velocity is determined from the steady-flow energy balance $\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$ with $q = w = 0$,

$$h_1 + V_1^2/2 = h_2 + V_2^2/2 \longrightarrow 0 = h_2 - h_1 + \frac{V_2^2 - V_1^2}{2}$$

Solving for V_2 ,

$$V_2 = \sqrt{2(h_1 - h_2)} = \sqrt{2(3196.7 - 3065.4) \text{ kJ/kg} \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = \mathbf{512.4 \text{ m/s}}$$

The mass flow rate is determined from

$$\dot{m} = \frac{1}{v_2} A_2 V_2 = \frac{1}{0.08666 \text{ m}^3/\text{kg}} (60 \times 10^{-4} \text{ m}^2)(512.4 \text{ m/s}) = \mathbf{35.47 \text{ kg/s}}$$

The velocity of sound at the exit of the nozzle is determined from

$$c = \left(\frac{\partial \mathcal{P}}{\partial \rho} \right)_s \cong \left(\frac{\Delta \mathcal{P}}{\Delta(1/v)} \right)_s^{1/2}$$

The specific volume of steam at $s_2 = 6.6622 \text{ kJ/kg} \cdot \text{K}$ and at pressures just below and just above the specified pressure (2.5 and 3.5 MPa) are determined to be 0.09981 and 0.07689 m^3/kg . Substituting,

$$c_2 = \sqrt{\frac{(3500 - 2500) \text{ kPa}}{\left(\frac{1}{0.07689} - \frac{1}{0.09981} \right) \text{ kg/m}^3} \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kPa} \cdot \text{m}^3} \right)} = 578.7 \text{ m/s}$$

Then the exit Mach number becomes

$$\text{Ma}_2 = \frac{V_2}{c_2} = \frac{512.4 \text{ m/s}}{578.7 \text{ m/s}} = \mathbf{0.885}$$

17-117E Steam enters a converging nozzle with a low velocity. The exit velocity, mass flow rate, and exit Mach number are to be determined for isentropic and 90 percent efficient nozzle cases.

Assumptions 1 Flow through the nozzle is steady and one-dimensional. **2** The nozzle is adiabatic.

Analysis (a) The inlet stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible. Thus $h_{01} = h_1$.

At the inlet,

$$\left. \begin{aligned} P_1 = P_{01} = 450 \text{ psia} \\ T_1 = T_{01} = 900^\circ\text{F} \end{aligned} \right\} \begin{aligned} h_1 = h_{01} = 1468.6 \text{ Btu/lbm} \\ s_1 = s_{2s} = 1.7117 \text{ Btu/lbm} \cdot \text{R} \end{aligned}$$

At the exit,

$$\left. \begin{aligned} P_2 = 275 \text{ psia} \\ s_{2s} = 1.7117 \text{ Btu/lbm} \cdot \text{R} \end{aligned} \right\} \begin{aligned} h_2 = 1400.5 \text{ Btu/lbm} \\ v_2 = 2.5732 \text{ ft}^3/\text{lbm} \end{aligned}$$

- a) $\eta_N = 100\%$
b) $\eta_N = 90\%$

Then the exit velocity is determined from the steady-flow energy balance $\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$ with $q = w = 0$,

$$h_1 + V_1^2/2 = h_2 + V_2^2/2 \longrightarrow 0 = h_2 - h_1 + \frac{V_2^2 - V_1^2}{2}$$

Solving for V_2 ,

$$V_2 = \sqrt{2(h_1 - h_2)} = \sqrt{2(1468.6 - 1400.5) \text{ Btu/lbm} \left(\frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right)} = \mathbf{1847 \text{ ft/s}}$$

Then,

$$\dot{m} = \frac{1}{v_2} A_2 V_2 = \frac{1}{2.5732 \text{ ft}^3/\text{lbm}} (3.75/144 \text{ ft}^2)(1847 \text{ ft/s}) = \mathbf{18.71 \text{ lbm/s}}$$

The velocity of sound at the exit of the nozzle is determined from

$$c = \left(\frac{\partial \mathcal{P}}{\partial \rho} \right)_s \cong \left(\frac{\Delta \mathcal{P}}{\Delta(1/v)} \right)_s$$

The specific volume of steam at $s_2 = 1.7117 \text{ Btu/lbm} \cdot \text{R}$ and at pressures just below and just above the specified pressure (250 and 300 psia) are determined to be 2.7709 and 2.4048 ft^3/lbm . Substituting,

$$c_2 = \sqrt{\frac{(300 - 250) \text{ psia}}{\left(\frac{1}{2.4048} - \frac{1}{2.7709} \right) \text{ lbm/ft}^3} \left(\frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right) \left(\frac{1 \text{ Btu}}{5.4039 \text{ ft}^3 \cdot \text{psia}} \right)} = 2053 \text{ ft/s}$$

Then the exit Mach number becomes

$$\text{Ma}_2 = \frac{V_2}{c_2} = \frac{1847 \text{ ft/s}}{2053 \text{ ft/s}} = \mathbf{0.900}$$

(b) The inlet stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible. Thus $h_{01} = h_1$.

At the inlet,

$$\left. \begin{aligned} P_1 = P_{01} = 450 \text{ psia} \\ T_1 = T_{01} = 900^\circ\text{F} \end{aligned} \right\} \begin{aligned} h_1 = h_{01} = 1468.6 \text{ Btu/lbm} \\ s_1 = s_{2s} = 1.7117 \text{ Btu/lbm} \cdot \text{R} \end{aligned}$$

At state 2s,

$$\left. \begin{array}{l} P_{2s} = 275 \text{ psia} \\ s_{2s} = 1.7117 \text{ Btu/lbm} \cdot \text{R} \end{array} \right\} h_{2s} = 1400.5 \text{ Btu/lbm}$$

The enthalpy of steam at the actual exit state is determined from

$$\eta_N = \frac{h_{01} - h_2}{h_{01} - h_{2s}} \longrightarrow 0.90 = \frac{1468.6 - h_2}{1468.6 - 1400.5} \longrightarrow h_2 = 1407.3 \text{ Btu/lbm}$$

Therefore,

$$\left. \begin{array}{l} P_2 = 275 \text{ psia} \\ h_2 = 1407.3 \text{ Btu/lbm} \end{array} \right\} \begin{array}{l} v_2 = 2.6034 \text{ ft}^3/\text{lbm} \\ s_2 = 1.7173 \text{ Btu/lbm} \cdot \text{R} \end{array}$$

Then the exit velocity is determined from the steady-flow energy balance $\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$ with $q = w = 0$,

$$h_1 + V_1^2/2 = h_2 + V_2^2/2 \longrightarrow 0 = h_2 - h_1 + \frac{V_2^2 - V_1^2}{2}$$

Solving for V_2 ,

$$V_2 = \sqrt{2(h_1 - h_2)} = \sqrt{2(1468.6 - 1407.3) \text{ Btu/lbm} \left(\frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right)} = \mathbf{1752 \text{ ft/s}}$$

Then,

$$\dot{m} = \frac{1}{v_2} A_2 V_2 = \frac{1}{2.6034 \text{ ft}^3/\text{lbm}} (3.75/144 \text{ ft}^2)(1752 \text{ ft/s}) = \mathbf{17.531 \text{ lbm/s}}$$

The velocity of sound at the exit of the nozzle is determined from

$$c = \left(\frac{\partial \mathcal{P}}{\partial \rho} \right)_s^{1/2} \cong \left(\frac{\Delta \mathcal{P}}{\Delta(1/v)} \right)_s^{1/2}$$

The specific volume of steam at $s_2 = 1.7173 \text{ Btu/lbm} \cdot \text{R}$ and at pressures just below and just above the specified pressure (250 and 300 psia) are determined to be 2.8036 and 2.4329 ft^3/lbm . Substituting,

$$c_2 = \sqrt{\frac{(300 - 250) \text{ psia}}{\left(\frac{1}{2.4329} - \frac{1}{2.8036} \right) \text{ lbm/ft}^3} \left(\frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right) \left(\frac{1 \text{ Btu}}{5.4039 \text{ ft}^3 \cdot \text{psia}} \right)} = 2065 \text{ ft/s}$$

Then the exit Mach number becomes

$$\text{Ma}_2 = \frac{V_2}{c_2} = \frac{1752 \text{ ft/s}}{2065 \text{ ft/s}} = \mathbf{0.849}$$

17-118 Steam enters a converging-diverging nozzle with a low velocity. The exit area and the exit Mach number are to be determined.

Assumptions Flow through the nozzle is steady, one-dimensional, and isentropic.

Analysis The inlet stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible. Thus $h_{01} = h_1$.

At the inlet,

$$\left. \begin{aligned} P_1 = P_{01} = 1 \text{ MPa} \\ T_1 = T_{01} = 500^\circ\text{C} \end{aligned} \right\} \begin{aligned} h_1 = h_{01} = 3479.1 \text{ kJ/kg} \\ s_1 = s_{2s} = 7.7642 \text{ kJ/kg} \cdot \text{K} \end{aligned}$$

At the exit,

$$\left. \begin{aligned} P_2 = 0.2 \text{ MPa} \\ s_2 = 7.7642 \text{ kJ/kg} \cdot \text{K} \end{aligned} \right\} \begin{aligned} h_2 = 3000.0 \text{ kJ/kg} \\ v_2 = 1.2325 \text{ m}^3/\text{kg} \end{aligned}$$

Then the exit velocity is determined from the steady-flow energy balance $\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$ with $q = w = 0$,

$$h_1 + V_1^2/2 = h_2 + V_2^2/2 \longrightarrow 0 = h_2 - h_1 + \frac{V_2^2 - V_1^2}{2}$$

Solving for V_2 ,

$$V_2 = \sqrt{2(h_1 - h_2)} = \sqrt{2(3479.1 - 3000.0) \text{ kJ/kg} \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 978.9 \text{ m/s}$$

The exit area is determined from

$$A_2 = \frac{\dot{m} v_2}{V_2} = \frac{(2.5 \text{ kg/s})(1.2325 \text{ m}^3/\text{kg})}{(978.9 \text{ m/s})} = 31.5 \times 10^{-4} \text{ m}^2 = \mathbf{31.5 \text{ cm}^2}$$

The velocity of sound at the exit of the nozzle is determined from

$$c = \left(\frac{\partial P}{\partial \rho} \right)_s^{1/2} \cong \left(\frac{\Delta P}{\Delta(1/v)} \right)_s^{1/2}$$

The specific volume of steam at $s_2 = 7.7642 \text{ kJ/kg} \cdot \text{K}$ and at pressures just below and just above the specified pressure (0.1 and 0.3 MPa) are determined to be 2.0935 and 0.9024 m^3/kg . Substituting,

$$c_2 = \sqrt{\frac{(300 - 100) \text{ kPa}}{\left(\frac{1}{0.9024} - \frac{1}{2.0935} \right) \text{ kg/m}^3} \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kPa} \cdot \text{m}^3} \right)} = 563.2 \text{ m/s}$$

Then the exit Mach number becomes

$$\text{Ma}_2 = \frac{V_2}{c_2} = \frac{978.9 \text{ m/s}}{563.2 \text{ m/s}} = \mathbf{1.738}$$

17-119 Steam enters a converging-diverging nozzle with a low velocity. The exit area and the exit Mach number are to be determined.

Assumptions Flow through the nozzle is steady and one-dimensional.

Analysis The inlet stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible. Thus $h_{01} = h_1$.

$$\text{At the inlet, } \left. \begin{array}{l} P_1 = P_{01} = 1 \text{ MPa} \\ T_1 = T_{01} = 500^\circ\text{C} \end{array} \right\} \begin{array}{l} h_1 = h_{01} = 3479.1 \text{ kJ/kg} \\ s_1 = s_{2s} = 7.7642 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\text{At state } 2s, \left. \begin{array}{l} P_2 = 0.2 \text{ MPa} \\ s_2 = 7.7642 \text{ kJ/kg} \cdot \text{K} \end{array} \right\} h_{2s} = 3000.0 \text{ kJ/kg}$$

The enthalpy of steam at the actual exit state is determined from

$$\eta_N = \frac{h_{01} - h_2}{h_{01} - h_{2s}} \longrightarrow 0.90 = \frac{3479.1 - h_2}{3479.1 - 3000.0} \longrightarrow h_2 = 3047.9 \text{ kJ/kg}$$

Therefore,

$$\left. \begin{array}{l} P_2 = 0.2 \text{ MPa} \\ h_2 = 3047.9 \text{ kJ/kg} \end{array} \right\} \begin{array}{l} v_2 = 1.2882 \text{ m}^3/\text{kg} \\ s_2 = 7.7642 \text{ kJ/kg} \cdot \text{K} \end{array}$$

Then the exit velocity is determined from the steady-flow energy balance $\dot{E}_{\text{in}} = \dot{E}_{\text{out}}$ with $q = w = 0$,

$$h_1 + V_1^2/2 = h_2 + V_2^2/2 \longrightarrow 0 = h_2 - h_1 + \frac{V_2^2 - V_1^2}{2}$$

Solving for V_2 ,

$$V_2 = \sqrt{2(h_1 - h_2)} = \sqrt{2(3479.1 - 3047.9) \text{ kJ/kg} \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 928.7 \text{ m/s}$$

The exit area is determined from

$$A_2 = \frac{\dot{m} v_2}{V_2} = \frac{(2.5 \text{ kg/s})(1.2882 \text{ m}^3/\text{kg})}{928.7 \text{ m/s}} = 34.7 \times 10^{-4} \text{ m}^2 = \mathbf{34.7 \text{ cm}^2}$$

The velocity of sound at the exit of the nozzle is determined from

$$c = \left(\frac{\partial P}{\partial \rho} \right)_s^{1/2} \cong \left(\frac{\Delta P}{\Delta(1/v)} \right)_s^{1/2}$$

The specific volume of steam at $s_2 = 7.7642 \text{ kJ/kg} \cdot \text{K}$ and at pressures just below and just above the specified pressure (0.1 and 0.3 MPa) are determined to be 2.1903 and 0.9425 m^3/kg . Substituting,

$$c_2 = \sqrt{\frac{(300 - 100) \text{ kPa}}{\left(\frac{1}{0.9425} - \frac{1}{2.1903} \right) \text{ kg/m}^3} \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kPa} \cdot \text{m}^3} \right)} = 575.2 \text{ m/s}$$

Then the exit Mach number becomes

$$\text{Ma}_2 = \frac{V_2}{c_2} = \frac{928.7 \text{ m/s}}{575.2 \text{ m/s}} = \mathbf{1.61}$$

Review Problems

17-120 The thrust developed by the engine of a Boeing 777 is about 380 kN. The mass flow rate of gases through the nozzle is to be determined.

Assumptions 1 Air is an ideal gas with constant specific heats. 2 Flow of combustion gases through the nozzle is isentropic. 3 Choked flow conditions exist at the nozzle exit. 4 The velocity of gases at the nozzle inlet is negligible.

Properties The gas constant of air is $R = 0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K}$, and it can also be used for combustion gases. The specific heat ratio of combustion gases is $k = 1.33$.

Analysis The velocity at the nozzle exit is the sonic speed, which is determined to be

$$V = c = \sqrt{kRT} = \sqrt{(1.33)(0.287 \text{ kJ/kg}\cdot\text{K})\left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}}\right)(220 \text{ K})} = 289.8 \text{ m/s}$$

Noting that thrust F is related to velocity by $F = \dot{m}V$, the mass flow rate of combustion gases is determined to be

$$\dot{m} = \frac{F}{V} = \frac{380,000 \text{ N}}{289.8 \text{ m/s}} \left(\frac{1 \text{ kg}\cdot\text{m}/\text{s}^2}{1 \text{ N}} \right) = 1311 \text{ kg/s} \cong \mathbf{1310 \text{ kg/s}}$$

Discussion The combustion gases are mostly nitrogen (due to the 78% of N_2 in air), and thus they can be treated as air with a good degree of approximation.

17-121 A stationary temperature probe is inserted into an air duct reads 85°C . The actual temperature of air is to be determined.

Assumptions 1 Air is an ideal gas with constant specific heats at room temperature. 2 The stagnation process is isentropic.

Properties The specific heat of air at room temperature is $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$.

Analysis The air that strikes the probe will be brought to a complete stop, and thus it will undergo a stagnation process. The thermometer will sense the temperature of this stagnated air, which is the stagnation temperature. The actual air temperature is determined from

$$T = T_0 - \frac{V^2}{2c_p} = 85^\circ\text{C} - \frac{(190 \text{ m/s})^2}{2 \times 1.005 \text{ kJ/kg}\cdot\text{K}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = \mathbf{67.0^\circ\text{C}}$$

Discussion Temperature rise due to stagnation is very significant in high-speed flows, and should always be considered when compressibility effects are not negligible.

17-122 Nitrogen flows through a heat exchanger. The stagnation pressure and temperature of the nitrogen at the inlet and the exit states are to be determined.

Assumptions 1 Nitrogen is an ideal gas with constant specific heats. 2 Flow of nitrogen through the heat exchanger is isentropic.

Properties The properties of nitrogen are $c_p = 1.039 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$.

Analysis The stagnation temperature and pressure of nitrogen at the inlet and the exit states are determined from

$$T_{01} = T_1 + \frac{V_1^2}{2c_p} = 10^\circ\text{C} + \frac{(100 \text{ m/s})^2}{2 \times 1.039 \text{ kJ/kg}\cdot^\circ\text{C}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = \mathbf{14.8^\circ\text{C}}$$

$$P_{01} = P_1 \left(\frac{T_{01}}{T_1} \right)^{k/(k-1)} = (150 \text{ kPa}) \left(\frac{288.0 \text{ K}}{283.2 \text{ K}} \right)^{1.4/(1.4-1)} = \mathbf{159 \text{ kPa}}$$

From the energy balance relation $E_{in} - E_{out} = \Delta E_{system}$ with $w = 0$

$$q_{in} = c_p(T_2 - T_1) + \frac{V_2^2 - V_1^2}{2} + \Delta pe \approx 0$$

$$150 \text{ kJ/kg} = (1.039 \text{ kJ/kg}\cdot^\circ\text{C})(T_2 - 10^\circ\text{C}) + \frac{(200 \text{ m/s})^2 - (100 \text{ m/s})^2}{2} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right)$$

$$T_2 = 139.9^\circ\text{C}$$

and

$$T_{02} = T_2 + \frac{V_2^2}{2c_p} = 139.9^\circ\text{C} + \frac{(200 \text{ m/s})^2}{2 \times 1.039 \text{ kJ/kg}\cdot^\circ\text{C}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = \mathbf{159^\circ\text{C}}$$

$$P_{02} = P_2 \left(\frac{T_{02}}{T_2} \right)^{k/(k-1)} = (100 \text{ kPa}) \left(\frac{432.3 \text{ K}}{413.1 \text{ K}} \right)^{1.4/(1.4-1)} = \mathbf{117 \text{ kPa}}$$

Discussion Note that the stagnation temperature and pressure can be very different than their thermodynamic counterparts when dealing with compressible flow.

17-123 The mass flow parameter $\dot{m}\sqrt{RT_0}/(AP_0)$ versus the Mach number for $k = 1.2, 1.4,$ and 1.6 in the range of $0 \leq \text{Ma} \leq 1$ is to be plotted.

Analysis The mass flow rate parameter $(\dot{m}\sqrt{RT_0})/P_0A$ can be expressed as

$$\frac{\dot{m}\sqrt{RT_0}}{P_0A} = \text{Ma}\sqrt{k} \left(\frac{2}{2+(k-1)M^2} \right)^{(k+1)/2(k-1)}$$

Thus,

Ma	$k = 1.2$	$k = 1.4$	$k = 1.6$
0.0	0	0	0
0.1	0.1089	0.1176	0.1257
0.2	0.2143	0.2311	0.2465
0.3	0.3128	0.3365	0.3582
0.4	0.4015	0.4306	0.4571
0.5	0.4782	0.5111	0.5407
0.6	0.5411	0.5763	0.6077
0.7	0.5894	0.6257	0.6578
0.8	0.6230	0.6595	0.6916
0.9	0.6424	0.6787	0.7106
1.0	0.6485	0.6847	0.7164

Discussion Note that the mass flow rate increases with increasing Mach number and specific heat ratio. It levels off at $\text{Ma} = 1$, and remains constant (choked flow).

17-124 The equivalent relation for the speed of sound is to be verified using thermodynamic relations.

Analysis The two relations are $c^2 = \left(\frac{\partial \mathcal{P}}{\partial \rho}\right)_s$ and $c^2 = k \left(\frac{\partial \mathcal{P}}{\partial \rho}\right)_T$

From $r = 1/\nu \longrightarrow dr = -d\nu/\nu^2$. Thus, $c^2 = \left(\frac{\partial \mathcal{P}}{\partial r}\right)_s = -\nu^2 \left(\frac{\partial \mathcal{P}}{\partial \nu}\right)_s = -\nu^2 \left(\frac{\partial \mathcal{P}}{\partial T} \frac{\partial T}{\partial \nu}\right)_s = -\nu^2 \left(\frac{\partial \mathcal{P}}{\partial T}\right)_s \left(\frac{\partial T}{\partial \nu}\right)_s$

From the cyclic rule,

$$(P, T, s): \left(\frac{\partial \mathcal{P}}{\partial T}\right)_s \left(\frac{\partial T}{\partial s}\right)_P \left(\frac{\partial s}{\partial \mathcal{P}}\right)_T = -1 \longrightarrow \left(\frac{\partial \mathcal{P}}{\partial T}\right)_s = -\left(\frac{\partial s}{\partial T}\right)_P \left(\frac{\partial \mathcal{P}}{\partial s}\right)_T$$

$$(T, \nu, s): \left(\frac{\partial T}{\partial \nu}\right)_s \left(\frac{\partial \nu}{\partial s}\right)_T \left(\frac{\partial s}{\partial T}\right)_\nu = -1 \longrightarrow \left(\frac{\partial T}{\partial \nu}\right)_s = -\left(\frac{\partial s}{\partial \nu}\right)_T \left(\frac{\partial T}{\partial s}\right)_\nu$$

Substituting,

$$c^2 = -\nu^2 \left(\frac{\partial s}{\partial T}\right)_P \left(\frac{\partial \mathcal{P}}{\partial s}\right)_T \left(\frac{\partial s}{\partial \nu}\right)_T \left(\frac{\partial T}{\partial s}\right)_\nu = -\nu^2 \left(\frac{\partial s}{\partial T}\right)_P \left(\frac{\partial T}{\partial s}\right)_\nu \left(\frac{\partial \mathcal{P}}{\partial \nu}\right)_T$$

Recall that $\frac{c_p}{T} = \left(\frac{\partial s}{\partial T}\right)_P$ and $\frac{c_v}{T} = \left(\frac{\partial s}{\partial T}\right)_\nu$. Substituting,

$$c^2 = -\nu^2 \left(\frac{c_p}{T}\right) \left(\frac{T}{c_v}\right) \left(\frac{\partial \mathcal{P}}{\partial \nu}\right)_T = -\nu^2 k \left(\frac{\partial \mathcal{P}}{\partial \nu}\right)_T$$

Replacing $-d\nu/\nu^2$ by $d\rho$, we get $c^2 = k \left(\frac{\partial \mathcal{P}}{\partial \rho}\right)_T$, which is the desired expression

Discussion Note that the differential thermodynamic property relations are very useful in the derivation of other property relations in differential form.

17-125 For ideal gases undergoing isentropic flows, expressions for P/P^* , T/T^* , and ρ/ρ^* as functions of k and Ma are to be obtained.

Analysis Equations 12-18 and 12-21 are given to be $\frac{T_0}{T} = \frac{2 + (k-1)\text{Ma}^2}{2}$ and $\frac{T^*}{T_0} = \frac{2}{k+1}$

Multiplying the two, $\left(\frac{T_0}{T} \frac{T^*}{T_0}\right) = \left(\frac{2 + (k-1)\text{Ma}^2}{2}\right) \left(\frac{2}{k+1}\right)$

Simplifying and inverting, $\frac{T}{T^*} = \frac{k+1}{2 + (k-1)\text{Ma}^2}$ (1)

From $\frac{P}{P^*} = \left(\frac{T}{T^*}\right)^{k/(k-1)} \longrightarrow \frac{P}{P^*} = \left(\frac{k+1}{2 + (k-1)\text{Ma}^2}\right)^{k/(k-1)}$ (2)

From $\frac{\rho}{\rho^*} = \left(\frac{P}{P^*}\right)^{k/(k-1)} \longrightarrow \frac{\rho}{\rho^*} = \left(\frac{k+1}{2 + (k-1)\text{Ma}^2}\right)^{k/(k-1)}$ (3)

Discussion Note that some very useful relations can be obtained by very simple manipulations.

17-126 It is to be verified that for the steady flow of ideal gases $dT_0/T = dA/A + (1-Ma^2) dV/V$. The effect of heating and area changes on the velocity of an ideal gas in steady flow for subsonic flow and supersonic flow are to be explained.

Analysis We start with the relation $\frac{V^2}{2} = c_p(T_0 - T)$ (1)

Differentiating, $VdV = c_p(dT_0 - dT)$ (2)

We also have $\frac{d\rho}{\rho} + \frac{dA}{A} + \frac{dV}{V} = 0$ (3)

and $\frac{dP}{\rho} + VdV = 0$ (4)

Differentiating the ideal gas relation $P = \rho RT$, $\frac{dP}{P} = \frac{d\rho}{\rho} + \frac{dT}{T} = 0$ (5)

From the speed of sound relation, $c^2 = kRT = (k-1)c_pT = kP/\rho$ (6)

Combining Eqs. (3) and (5), $\frac{dP}{P} - \frac{dT}{T} + \frac{dA}{A} + \frac{dV}{V} = 0$ (7)

Combining Eqs. (4) and (6), $\frac{dP}{\rho} = \frac{dP}{kP/c^2} = -VdV$

or, $\frac{dP}{P} = -\frac{k}{C^2} VdV = -k \frac{V^2}{C^2} \frac{dV}{V} = -kMa^2 \frac{dV}{V}$ (8)

Combining Eqs. (2) and (6), $dT = dT_0 - V \frac{dV}{c_p}$

or, $\frac{dT}{T} = \frac{dT_0}{T} - \frac{V^2}{C_p T} \frac{dV}{V} = \frac{dT}{T} = \frac{dT_0}{T} - \frac{V^2}{C^2/(k-1)} \frac{dV}{V} = \frac{dT_0}{T} - (k-1)Ma^2 \frac{dV}{V}$ (9)

Combining Eqs. (7), (8), and (9), $-(k-1)Ma^2 \frac{dV}{V} - \frac{dT_0}{T} + (k-1)Ma^2 \frac{dV}{V} + \frac{dA}{A} + \frac{dV}{V} = 0$

or, $\frac{dT_0}{T} = \frac{dA}{A} + [-kMa^2 + (k-1)Ma^2 + 1] \frac{dV}{V}$

Thus, $\boxed{\frac{dT_0}{T} = \frac{dA}{A} + (1-Ma^2) \frac{dV}{V}}$ (10)

Differentiating the steady-flow energy equation $q = h_{02} - h_{01} = c_p(T_{02} - T_{01})$

$$\delta q = c_p dT_0 \quad (11)$$

Eq. (11) relates the stagnation temperature change dT_0 to the net heat transferred to the fluid. Eq. (10) relates the velocity changes to area changes dA , and the stagnation temperature change dT_0 or the heat transferred.

(a) When $Ma < 1$ (subsonic flow), **the fluid accelerates if the duct converges ($dA < 0$) or the fluid is heated ($dT_0 > 0$ or $\delta q > 0$). The fluid decelerates if the duct diverges ($dA > 0$) or the fluid is cooled ($dT_0 < 0$ or $\delta q < 0$).**

(b) When $Ma > 1$ (supersonic flow), **the fluid accelerates if the duct diverges ($dA > 0$) or the fluid is cooled ($dT_0 < 0$ or $\delta q < 0$). The fluid decelerates if the duct converges ($dA < 0$) or the fluid is heated ($dT_0 > 0$ or $\delta q > 0$).**

Discussion Some of these results are not intuitively obvious, but come about by satisfying the conservation equations.

17-127 A Pitot-static probe measures the difference between the static and stagnation pressures for a subsonic airplane. The speed of the airplane and the flight Mach number are to be determined.

Assumptions **1** Air is an ideal gas with a constant specific heat ratio. **2** The stagnation process is isentropic.

Properties The properties of air are $R = 0.287 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$.

Analysis The stagnation pressure of air at the specified conditions is

$$P_0 = P + \Delta P = 54 + 16 = 70 \text{ kPa}$$

Then,

$$\frac{P_0}{P} = \left(1 + \frac{(k-1)\text{Ma}^2}{2}\right)^{k/k-1} \longrightarrow \frac{70}{54} = \left(1 + \frac{(1.4-1)\text{Ma}^2}{2}\right)^{1.4/0.4}$$

It yields

$$\mathbf{Ma = 0.620}$$

The speed of sound in air at the specified conditions is

$$c = \sqrt{kRT} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(256 \text{ K})\left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}}\right)} = 320.7 \text{ m/s}$$

Thus,

$$V = \text{Ma} \times c = (0.620)(320.7 \text{ m/s}) = \mathbf{199 \text{ m/s}}$$

Discussion Note that the flow velocity can be measured in a simple and accurate way by simply measuring pressure.

17-128 An expression for the speed of sound based on van der Waals equation of state is to be derived. Using this relation, the speed of sound in carbon dioxide is to be determined and compared to that obtained by ideal gas behavior.

Properties The properties of CO₂ are $R = 0.1889 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.279$ at $T = 50^\circ\text{C} = 323.2 \text{ K}$.

Analysis Van der Waals equation of state can be expressed as $P = \frac{RT}{v-b} - \frac{a}{v^2}$.

Differentiating,
$$\left(\frac{\partial P}{\partial v}\right)_T = \frac{RT}{(v-b)^2} + \frac{2a}{v^3}$$

Noting that $\rho = 1/v \longrightarrow d\rho = -dv/v^2$, the speed of sound relation becomes

Substituting,
$$c^2 = k\left(\frac{\partial P}{\partial v}\right)_T = v^2 k\left(\frac{\partial P}{\partial v}\right)_T$$

$$c^2 = \frac{v^2 kRT}{(v-b)^2} - \frac{2ak}{v}$$

Using the molar mass of CO₂ ($M = 44 \text{ kg/kmol}$), the constant a and b can be expressed per unit mass as

$$a = 0.1882 \text{ kPa}\cdot\text{m}^6/\text{kg}^2 \quad \text{and} \quad b = 9.70 \times 10^{-4} \text{ m}^3/\text{kg}$$

The specific volume of CO₂ is determined to be

$$200 \text{ kPa} = \frac{(0.1889 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(323.2 \text{ K})}{v - 0.000970 \text{ m}^3/\text{kg}} - \frac{2 \times 0.1882 \text{ kPa}\cdot\text{m}^6/\text{kg}^2}{v^2} \rightarrow v = 0.300 \text{ m}^3/\text{kg}$$

Substituting,

$$c = \left(\left(\frac{(0.300 \text{ m}^3/\text{kg})^2 (1.279)(0.1889 \text{ kJ/kg}\cdot\text{K})(323.2 \text{ K})}{(0.300 - 0.000970 \text{ m}^3/\text{kg})^2} - \frac{2(0.1882 \text{ kPa}\cdot\text{m}^6/\text{kg}^3)(1.279)}{(0.300 \text{ m}^3/\text{kg})^2} \right) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kPa}\cdot\text{m}^3/\text{kg}} \right) \right)^{1/2}$$

$$= \mathbf{271 \text{ m/s}}$$

If we treat CO₂ as an ideal gas, the speed of sound becomes

$$c = \sqrt{kRT} = \sqrt{(1.279)(0.1889 \text{ kJ/kg}\cdot\text{K})(323.2 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = \mathbf{279 \text{ m/s}}$$

Discussion Note that the ideal gas relation is the simplest equation of state, and it is very accurate for most gases encountered in practice. At high pressures and/or low temperatures, however, the gases deviate from ideal gas behavior, and it becomes necessary to use more complicated equations of state.

17-129 Helium gas is accelerated in a nozzle. The pressure and temperature of helium at the location where $Ma = 1$ and the ratio of the flow area at this location to the inlet flow area are to be determined.

Assumptions **1** Helium is an ideal gas with constant specific heats. **2** Flow through the nozzle is steady, one-dimensional, and isentropic.

Properties The properties of helium are $R = 2.0769 \text{ kJ/kg}\cdot\text{K}$, $c_p = 5.1926 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.667$.

Analysis The properties of the fluid at the location where $Ma = 1$ are the critical properties, denoted by superscript *. We first determine the stagnation temperature and pressure, which remain constant throughout the nozzle since the flow is isentropic.

$$T_0 = T_i + \frac{V_i^2}{2c_p} = 560 \text{ K} + \frac{(120 \text{ m/s})^2}{2 \times 5.1926 \text{ kJ/kg}\cdot\text{K}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 561.4 \text{ K}$$

and

$$P_0 = P_i \left(\frac{T_0}{T_i} \right)^{k/(k-1)} = (0.6 \text{ MPa}) \left(\frac{561.4 \text{ K}}{560 \text{ K}} \right)^{1.667/(1.667-1)} = 0.6037 \text{ MPa}$$

The Mach number at the nozzle exit is given to be $Ma = 1$. Therefore, the properties at the nozzle exit are the *critical properties* determined from

$$T^* = T_0 \left(\frac{2}{k+1} \right) = (561.4 \text{ K}) \left(\frac{2}{1.667+1} \right) = 421.0 \text{ K} = \mathbf{421 \text{ K}}$$

$$P^* = P_0 \left(\frac{2}{k+1} \right)^{k/(k-1)} = (0.6037 \text{ MPa}) \left(\frac{2}{1.667+1} \right)^{1.667/(1.667-1)} = 0.2941 \text{ MPa} \cong \mathbf{0.294 \text{ MPa}}$$

The speed of sound and the Mach number at the nozzle inlet are

$$c_i = \sqrt{kRT_i} = \sqrt{(1.667)(2.0769 \text{ kJ/kg}\cdot\text{K})(560 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 1392 \text{ m/s}$$

$$Ma_i = \frac{V_i}{c_i} = \frac{120 \text{ m/s}}{1392 \text{ m/s}} = 0.08618$$

The ratio of the entrance-to-throat area is

$$\begin{aligned} \frac{A_i}{A^*} &= \frac{1}{Ma_i} \left[\left(\frac{2}{k+1} \right) \left(1 + \frac{k-1}{2} Ma_i^2 \right) \right]^{(k+1)/(2(k-1))} \\ &= \frac{1}{0.08618} \left[\left(\frac{2}{1.667+1} \right) \left(1 + \frac{1.667-1}{2} (0.08618)^2 \right) \right]^{2.667/(2 \times 0.667)} \\ &= 8.745 \end{aligned}$$

Then the ratio of the throat area to the entrance area becomes

$$\frac{A^*}{A_i} = \frac{1}{8.745} = 0.1144 \cong \mathbf{0.114}$$

Discussion The compressible flow functions are essential tools when determining the proper shape of the compressible flow duct.

17-130 Helium gas enters a nozzle with negligible velocity, and is accelerated in a nozzle. The pressure and temperature of helium at the location where $Ma = 1$ and the ratio of the flow area at this location to the inlet flow area are to be determined.

Assumptions **1** Helium is an ideal gas with constant specific heats. **2** Flow through the nozzle is steady, one-dimensional, and isentropic. **3** The entrance velocity is negligible.

Properties The properties of helium are $R = 2.0769 \text{ kJ/kg}\cdot\text{K}$, $c_p = 5.1926 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.667$.

Analysis We treat helium as an ideal gas with $k = 1.667$. The properties of the fluid at the location where $Ma = 1$ are the critical properties, denoted by superscript $*$.

The stagnation temperature and pressure in this case are identical to the inlet temperature and pressure since the inlet velocity is negligible. They remain constant throughout the nozzle since the flow is isentropic.

$$T_0 = T_i = 560 \text{ K}$$

$$P_0 = P_i = 0.6 \text{ MPa}$$

The Mach number at the nozzle exit is given to be $Ma = 1$. Therefore, the properties at the nozzle exit are the *critical properties* determined from

$$T^* = T_0 \left(\frac{2}{k+1} \right) = (560 \text{ K}) \left(\frac{2}{1.667+1} \right) = \mathbf{420 \text{ K}}$$

$$P^* = P_0 \left(\frac{2}{k+1} \right)^{k/(k-1)} = (0.6 \text{ MPa}) \left(\frac{2}{1.667+1} \right)^{1.667/(1.667-1)} = \mathbf{0.292 \text{ MPa}}$$

The ratio of the nozzle inlet area to the throat area is determined from

$$\frac{A_i}{A^*} = \frac{1}{Ma_i} \left[\left(\frac{2}{k+1} \right) \left(1 + \frac{k-1}{2} Ma_i^2 \right) \right]^{(k+1)/[2(k-1)]}$$

But the Mach number at the nozzle inlet is $Ma = 0$ since $V_i \cong 0$. Thus the ratio of the throat area to the nozzle inlet area is

$$\frac{A^*}{A_i} = \frac{1}{\infty} = \mathbf{0}$$

Discussion The compressible flow functions are essential tools when determining the proper shape of the compressible flow duct.

17-131 Air enters a converging nozzle. The mass flow rate, the exit velocity, the exit Mach number, and the exit pressure-stagnation pressure ratio versus the back pressure-stagnation pressure ratio for a specified back pressure range are to be calculated and plotted.

Assumptions **1** Air is an ideal gas with constant specific heats at room temperature. **2** Flow through the nozzle is steady, one-dimensional, and isentropic.

Properties The properties of air at room temperature are $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$.

Analysis We use EES to tabulate and plot the results. The stagnation properties remain constant throughout the nozzle since the flow is isentropic. They are determined from

$$T_0 = T_i + \frac{V_i^2}{2c_p} = 400 \text{ K} + \frac{(180 \text{ m/s})^2}{2 \times 1.005 \text{ kJ/kg}\cdot\text{K}} \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 416.1 \text{ K}$$

$$P_0 = P_i \left(\frac{T_0}{T_i} \right)^{k/(k-1)} = (900 \text{ kPa}) \left(\frac{416.1 \text{ K}}{400 \text{ K}} \right)^{1.4/(1.4-1)} = 1033.3 \text{ kPa}$$

The critical pressure is determined to be

$$P^* = P_0 \left(\frac{2}{k+1} \right)^{k/(k-1)} = (1033.3 \text{ kPa}) \left(\frac{2}{1.4+1} \right)^{1.4/0.4} = 545.9 \text{ kPa}$$

Then the pressure at the exit plane (throat) is

$$P_e = P_b \quad \text{for } P_b \geq 545.9 \text{ kPa}$$

$$P_e = P^* = 545.9 \text{ kPa} \quad \text{for } P_b < 545.9 \text{ kPa} \text{ (choked flow)}$$

Thus the back pressure does not affect the flow when $100 < P_b < 545.9 \text{ kPa}$. For a specified exit pressure P_e , the temperature, velocity, and mass flow rate are

$$\text{Temperature} \quad T_e = T_0 \left(\frac{P_e}{P_0} \right)^{(k-1)/k} = (416.1 \text{ K}) \left(\frac{P_e}{1033.3} \right)^{0.4/1.4}$$

$$\text{Velocity } V = \sqrt{2c_p(T_0 - T_e)} = \sqrt{2(1.005 \text{ kJ/kg}\cdot\text{K})(416.1 - T_e) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)}$$

$$\text{Speed of sound} \quad c_e = \sqrt{kRT_e} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)}$$

$$\text{Mach number} \quad \text{Ma}_e = V_e / c_e$$

$$\text{Density} \quad \rho_e = \frac{P_e}{RT_e} = \frac{P_e}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})T_e}$$

$$\text{Mass flow rate} \quad \dot{m} = \rho_e V_e A_e = \rho_e V_e (0.001 \text{ m}^2)$$

$P_b, \text{ kPa}$	P_b, P_0	$P_e, \text{ kPa}$	P_b, P_0	$T_e, \text{ K}$	$V_e, \text{ m/s}$	Ma	$\rho_e, \text{ kg/m}^3$	$\dot{m}, \text{ kg/s}$

Discussion Once the back pressure drops below 545.0 kPa, the flow is choked, and \dot{m} remains constant from then on.

17-132 Nitrogen gas enters a converging nozzle. The properties at the nozzle exit are to be determined.

Assumptions 1 Nitrogen is an ideal gas with $k = 1.4$. 2 Flow through the nozzle is steady, one-dimensional, and isentropic.

Analysis The schematic of the duct is shown in Fig. 12–25. For isentropic flow through a duct, the area ratio A/A^* (the flow area over the area of the throat where $Ma = 1$) is also listed in Table A–32. At the initial Mach number of $Ma = 0.3$, we read

$$\frac{A_1}{A^*} = 2.0351, \quad \frac{T_1}{T_0} = 0.9823, \quad \text{and} \quad \frac{P_1}{P_0} = 0.9395$$

With a 20 percent reduction in flow area, $A_2 = 0.8A_1$, and

$$\frac{A_2}{A^*} = \frac{A_2}{A_1} \frac{A_1}{A^*} = (0.8)(2.0351) = 1.6281$$

For this value of A_2/A^* from Table A–32, we read

$$\frac{T_2}{T_0} = 0.9791, \quad \frac{P_2}{P_0} = 0.8993, \quad \text{and} \quad Ma_2 = \mathbf{0.391}$$

Here we chose the subsonic Mach number for the calculated A_2/A^* instead of the supersonic one because the duct is converging in the flow direction and the initial flow is subsonic. Since the stagnation properties are constant for isentropic flow, we can write

$$\frac{T_2}{T_1} = \frac{T_2/T_0}{T_1/T_0} \quad \rightarrow \quad T_2 = T_1 \left(\frac{T_2/T_0}{T_1/T_0} \right) = (400 \text{ K}) \left(\frac{0.9791}{0.9823} \right) = \mathbf{399 \text{ K}}$$

$$\frac{P_2}{P_1} = \frac{P_2/P_0}{P_1/P_0} \quad \rightarrow \quad P_2 = P_1 \left(\frac{P_2/P_0}{P_1/P_0} \right) = (100 \text{ kPa}) \left(\frac{0.8993}{0.9395} \right) = \mathbf{95.7 \text{ K}}$$

which are the temperature and pressure at the desired location.

Discussion Note that the temperature and pressure drop as the fluid accelerates in a converging nozzle.

17-133 Nitrogen gas enters a converging nozzle. The properties at the nozzle exit are to be determined.

Assumptions 1 Nitrogen is an ideal gas with $k = 1.4$. 2 Flow through the nozzle is steady, one-dimensional, and isentropic.

Analysis The schematic of the duct is shown in Fig. 12–25. For isentropic flow through a duct, the area ratio A/A^* (the flow area over the area of the throat where $\text{Ma} = 1$) is also listed in Table A–32. At the initial Mach number of $\text{Ma} = 0.5$, we read

$$\frac{A_1}{A^*} = 1.3398, \quad \frac{T_1}{T_0} = 0.9524, \quad \text{and} \quad \frac{P_1}{P_0} = 0.8430$$

With a 20 percent reduction in flow area, $A_2 = 0.8A_1$, and

$$\frac{A_2}{A^*} = \frac{A_2}{A_1} \frac{A_1}{A^*} = (0.8)(1.3398) = 1.0718$$

For this value of A_2/A^* from Table A–32, we read

$$\frac{T_2}{T_0} = 0.9010, \quad \frac{P_2}{P_0} = 0.6948, \quad \text{and} \quad \text{Ma}_2 = \mathbf{0.740}$$

Here we chose the subsonic Mach number for the calculated A_2/A^* instead of the supersonic one because the duct is converging in the flow direction and the initial flow is subsonic. Since the stagnation properties are constant for isentropic flow, we can write

$$\frac{T_2}{T_1} = \frac{T_2/T_0}{T_1/T_0} \quad \rightarrow \quad T_2 = T_1 \left(\frac{T_2/T_0}{T_1/T_0} \right) = (400 \text{ K}) \left(\frac{0.9010}{0.9524} \right) = \mathbf{378 \text{ K}}$$

$$\frac{P_2}{P_1} = \frac{P_2/P_0}{P_1/P_0} \quad \rightarrow \quad P_2 = P_1 \left(\frac{P_2/P_0}{P_1/P_0} \right) = (100 \text{ kPa}) \left(\frac{0.6948}{0.8430} \right) = \mathbf{82.4 \text{ K}}$$

which are the temperature and pressure at the desired location.

Discussion Note that the temperature and pressure drop as the fluid accelerates in a converging nozzle.

17-134 Nitrogen entering a converging-diverging nozzle experiences a normal shock. The pressure, temperature, velocity, Mach number, and stagnation pressure downstream of the shock are to be determined. The results are to be compared to those of air under the same conditions.

Assumptions **1** Nitrogen is an ideal gas with constant specific heats. **2** Flow through the nozzle is steady, one-dimensional, and isentropic. **3** The nozzle is adiabatic.

Properties The properties of nitrogen are $R = 0.297 \text{ kJ/kg}\cdot\text{K}$ and $k = 1.4$.

Analysis The inlet stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible. Assuming the flow before the shock to be isentropic,

$$P_{01} = P_i = 620 \text{ kPa}$$

$$T_{01} = T_i = 310 \text{ K}$$

Then,

$$T_1 = T_{01} \left(\frac{2}{2 + (k-1)\text{Ma}_1^2} \right) = (310 \text{ K}) \left(\frac{2}{2 + (1.4-1)3^2} \right) = 110.7 \text{ K}$$

and

$$P_1 = P_{01} \left(\frac{T_1}{T_{01}} \right)^{k/(k-1)} = (620 \text{ kPa}) \left(\frac{110.7}{310} \right)^{1.4/0.4} = 16.88 \text{ kPa}$$

The fluid properties after the shock (denoted by subscript 2) are related to those before the shock through the functions listed in Table A-33. For $\text{Ma}_1 = 3.0$ we read

$$\text{Ma}_2 = 0.4752 \cong \mathbf{0.475}, \quad \frac{P_{02}}{P_{01}} = 0.32834, \quad \frac{P_2}{P_1} = 10.333, \quad \text{and} \quad \frac{T_2}{T_1} = 2.679$$

Then the stagnation pressure P_{02} , static pressure P_2 , and static temperature T_2 , are determined to be

$$P_{02} = 0.32834 P_{01} = (0.32834)(620 \text{ kPa}) = 203.6 \text{ kPa} \cong \mathbf{204 \text{ kPa}}$$

$$P_2 = 10.333 P_1 = (10.333)(16.88 \text{ kPa}) = 174.4 \text{ kPa} \cong \mathbf{174 \text{ kPa}}$$

$$T_2 = 2.679 T_1 = (2.679)(110.7 \text{ K}) = 296.6 \text{ K} \cong \mathbf{297 \text{ K}}$$

The velocity after the shock can be determined from $V_2 = \text{Ma}_2 c_2$, where c_2 is the speed of sound at the exit conditions after the shock,

$$V_2 = \text{Ma}_2 c_2 = \text{Ma}_2 \sqrt{kRT_2} = (0.4752) \sqrt{(1.4)(0.297 \text{ kJ/kg}\cdot\text{K})(296.6 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 166.9 \text{ m/s} \cong \mathbf{167 \text{ m/s}}$$

Discussion For *air* at specified conditions $k = 1.4$ (same as nitrogen) and $R = 0.287 \text{ kJ/kg}\cdot\text{K}$. Thus the only quantity which will be different in the case of air is the velocity after the normal shock, which happens to be 164.0 m/s.

17-135 The diffuser of an aircraft is considered. The static pressure rise across the diffuser and the exit area are to be determined.

Assumptions 1 Air is an ideal gas with constant specific heats at room temperature. 2 Flow through the diffuser is steady, one-dimensional, and isentropic. 3 The diffuser is adiabatic.

Properties Air properties at room temperature are $R = 0.287 \text{ kJ/kg}\cdot\text{K}$, $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.4$.

Analysis The inlet velocity is

$$V_1 = \text{Ma}_1 c_1 = M_1 \sqrt{kRT_1} = (0.9) \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(242.7 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 281.0 \text{ m/s}$$

Then the stagnation temperature and pressure at the diffuser inlet become

$$T_{01} = T_1 + \frac{V_1^2}{2c_p} = 242.7 + \frac{(281.0 \text{ m/s})^2}{2(1.005 \text{ kJ/kg}\cdot\text{K}) \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right)} = 282.0 \text{ K}$$

$$P_{01} = P_1 \left(\frac{T_{01}}{T_1} \right)^{k/(k-1)} = (41.1 \text{ kPa}) \left(\frac{282.0 \text{ K}}{242.7 \text{ K}} \right)^{1.4/(1.4-1)} = 69.50 \text{ kPa}$$

For an adiabatic diffuser, the energy equation reduces to $h_{01} = h_{02}$. Noting that $h = c_p T$ and the specific heats are assumed to be constant, we have

$$T_{01} = T_{02} = T_0 = 282.0 \text{ K}$$

The isentropic relation between states 1 and 02 gives

$$P_{02} = P_{01} = P_1 \left(\frac{T_{02}}{T_1} \right)^{k/(k-1)} = (41.1 \text{ kPa}) \left(\frac{282.0 \text{ K}}{242.7 \text{ K}} \right)^{1.4/(1.4-1)} = 69.50 \text{ kPa}$$

The exit velocity can be expressed as

$$V_2 = \text{Ma}_2 c_2 = \text{Ma}_2 \sqrt{kRT_2} = (0.3) \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K}) T_2 \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 6.01 \sqrt{T_2}$$

$$\text{Thus } T_2 = T_{02} - \frac{V_2^2}{2c_p} = (282.0) - \frac{6.01^2 T_2 \text{ m}^2/\text{s}^2}{2(1.005 \text{ kJ/kg}\cdot\text{K}) \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right)} = 277.0 \text{ K}$$

Then the static exit pressure becomes

$$P_2 = P_{02} \left(\frac{T_2}{T_{02}} \right)^{k/(k-1)} = (69.50 \text{ kPa}) \left(\frac{277.0 \text{ K}}{282.0 \text{ K}} \right)^{1.4/(1.4-1)} = 65.28 \text{ kPa}$$

Thus the static pressure rise across the diffuser is

$$\Delta P = P_2 - P_1 = 65.28 - 41.1 = \mathbf{24.2 \text{ kPa}}$$

$$\text{Also, } \rho_2 = \frac{P_2}{RT_2} = \frac{65.28 \text{ kPa}}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(277.0 \text{ K})} = 0.8211 \text{ kg/m}^3$$

$$V_2 = 6.01 \sqrt{T_2} = 6.01 \sqrt{277.0} = 100.0 \text{ m/s}$$

$$\text{Thus } A_2 = \frac{\dot{m}}{\rho_2 V_2} = \frac{38 \text{ kg/s}}{(0.8211 \text{ kg/m}^3)(100.0 \text{ m/s})} = \mathbf{0.463 \text{ m}^2}$$

Discussion The pressure rise in actual diffusers will be lower because of the irreversibilities. However, flow through well-designed diffusers is very nearly isentropic.

17-136 The critical temperature, pressure, and density of an equimolar mixture of oxygen and nitrogen for specified stagnation properties are to be determined.

Assumptions Both oxygen and nitrogen are ideal gases with constant specific heats at room temperature.

Properties The specific heat ratio and molar mass are $k = 1.395$ and $M = 32$ kg/kmol for oxygen, and $k = 1.4$ and $M = 28$ kg/kmol for nitrogen.

Analysis The gas constant of the mixture is

$$M_m = y_{O_2} M_{O_2} + y_{N_2} M_{N_2} = 0.5 \times 32 + 0.5 \times 28 = 30 \text{ kg/kmol}$$

$$R_m = \frac{R_u}{M_m} = \frac{8.314 \text{ kJ/kmol} \cdot \text{K}}{30 \text{ kg/kmol}} = 0.2771 \text{ kJ/kg} \cdot \text{K}$$

The specific heat ratio is 1.4 for nitrogen, and nearly 1.4 for oxygen. Therefore, the specific heat ratio of the mixture is also 1.4. Then the critical temperature, pressure, and density of the mixture become

$$T^* = T_0 \left(\frac{2}{k+1} \right) = (550 \text{ K}) \left(\frac{2}{1.4+1} \right) = 458.3 \text{ K} \cong \mathbf{458 \text{ K}}$$

$$P^* = P_0 \left(\frac{2}{k+1} \right)^{k/(k-1)} = (350 \text{ kPa}) \left(\frac{2}{1.4+1} \right)^{1.4/(1.4-1)} = 184.9 \text{ kPa} \cong \mathbf{185 \text{ kPa}}$$

$$\rho^* = \frac{P^*}{RT^*} = \frac{184.9 \text{ kPa}}{(0.2771 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(458.3 \text{ K})} = \mathbf{1.46 \text{ kg/m}^3}$$

Discussion If the specific heat ratios k of the two gases were different, then we would need to determine the k of the mixture from $k = c_{p,m}/c_{v,m}$ where the specific heats of the mixture are determined from

$$C_{p,m} = mf_{O_2} c_{p,O_2} + mf_{N_2} c_{p,N_2} = (y_{O_2} M_{O_2} / M_m) c_{p,O_2} + (y_{N_2} M_{N_2} / M_m) c_{p,N_2}$$

$$C_{v,m} = mf_{O_2} c_{v,O_2} + mf_{N_2} c_{v,N_2} = (y_{O_2} M_{O_2} / M_m) c_{v,O_2} + (y_{N_2} M_{N_2} / M_m) c_{v,N_2}$$

where mf is the mass fraction and y is the mole fraction. In this case it would give

$$c_{p,m} = (0.5 \times 32 / 30) \times 0.918 + (0.5 \times 28 / 30) \times 1.039 = 0.974 \text{ kJ/kg} \cdot \text{K}$$

$$c_{v,m} = (0.5 \times 32 / 30) \times 0.658 + (0.5 \times 28 / 30) \times 0.743 = 0.698 \text{ kJ/kg} \cdot \text{K}$$

and

$$k = 0.974 / 0.698 = 1.40$$

17-137E Helium gas is accelerated in a nozzle. For a specified mass flow rate, the throat and exit areas of the nozzle are to be determined for the case of isentropic nozzle.

Assumptions **1** Helium is an ideal gas with constant specific heats. **2** Flow through the nozzle is steady, one-dimensional, and isentropic. **3** The nozzle is adiabatic.

Properties The properties of helium are $R = 0.4961 \text{ Btu/lbm}\cdot\text{R} = 2.6809 \text{ psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R}$, $c_p = 1.25 \text{ Btu/lbm}\cdot\text{R}$, and $k = 1.667$.

Analysis The inlet stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible,

$$T_{01} = T_1 = 740 \text{ R}$$

$$P_{01} = P_1 = 220 \text{ psia}$$

The flow is assumed to be isentropic, thus the stagnation temperature and pressure remain constant throughout the nozzle,

$$T_{02} = T_{01} = 740 \text{ R}$$

$$P_{02} = P_{01} = 220 \text{ psia}$$

The critical pressure and temperature are determined from

$$T^* = T_0 \left(\frac{2}{k+1} \right) = (740 \text{ R}) \left(\frac{2}{1.667+1} \right) = 554.9 \text{ R}$$

$$P^* = P_0 \left(\frac{2}{k+1} \right)^{k/(k-1)} = (220 \text{ psia}) \left(\frac{2}{1.667+1} \right)^{1.667/(1.667-1)} = 107.2 \text{ psia}$$

$$\rho^* = \frac{P^*}{RT^*} = \frac{107.2 \text{ psia}}{(2.6809 \text{ psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R})(554.9 \text{ R})} = 0.07203 \text{ lbm/ft}^3$$

$$V^* = c^* = \sqrt{kRT^*} = \sqrt{(1.667)(0.4961 \text{ Btu/lbm}\cdot\text{R})(554.9 \text{ R}) \left(\frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right)} = 3390 \text{ ft/s}$$

and
$$A^* = \frac{\dot{m}}{\rho^* V^*} = \frac{0.2 \text{ lbm/s}}{(0.07203 \text{ lbm/ft}^3)(3390 \text{ ft/s})} = \mathbf{8.19 \times 10^{-4} \text{ ft}^2}$$

At the nozzle exit the pressure is $P_2 = 15 \text{ psia}$. Then the other properties at the nozzle exit are determined to be

$$\frac{P_0}{P_2} = \left(1 + \frac{k-1}{2} \text{Ma}_2^2 \right)^{k/(k-1)} \longrightarrow \frac{220 \text{ psia}}{15 \text{ psia}} = \left(1 + \frac{1.667-1}{2} \text{Ma}_2^2 \right)^{1.667/0.667}$$

It yields $\text{Ma}_2 = 2.405$, which is greater than 1. Therefore, the nozzle must be converging-diverging.

$$T_2 = T_0 \left(\frac{2}{2 + (k-1)\text{Ma}_2^2} \right) = (740 \text{ R}) \left(\frac{2}{2 + (1.667-1) \times 2.405^2} \right) = 252.6 \text{ R}$$

$$\rho_2 = \frac{P_2}{RT_2} = \frac{15 \text{ psia}}{(2.6809 \text{ psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R})(252.6 \text{ R})} = 0.02215 \text{ lbm/ft}^3$$

$$V_2 = \text{Ma}_2 c_2 = \text{Ma}_2 \sqrt{kRT_2} = (2.405) \sqrt{(1.667)(0.4961 \text{ Btu/lbm}\cdot\text{R})(252.6 \text{ R}) \left(\frac{25,037 \text{ ft}^2/\text{s}^2}{1 \text{ Btu/lbm}} \right)} = 5500 \text{ ft/s}$$

Thus the exit area is

$$A_2 = \frac{\dot{m}}{\rho_2 V_2} = \frac{0.2 \text{ lbm/s}}{(0.02215 \text{ lbm/ft}^3)(5500 \text{ ft/s})} = \mathbf{0.00164 \text{ ft}^2}$$

Discussion Flow areas in actual nozzles would be somewhat larger to accommodate the irreversibilities.

17-138 Using the compressible flow relations, the one-dimensional compressible flow functions are to be evaluated and tabulated as in Table A-32 for an ideal gas with $k = 1.667$.

Properties The specific heat ratio of the ideal gas is given to be $k = 1.667$.

Analysis The compressible flow functions listed below are expressed in EES and the results are tabulated.

$$\text{Ma}^* = \text{Ma} \sqrt{\frac{k+1}{2+(k-1)\text{Ma}^2}} \quad \frac{A}{A^*} = \frac{1}{\text{Ma}} \left[\left(\frac{2}{k+1} \right) \left(1 + \frac{k-1}{2} \text{Ma}^2 \right) \right]^{0.5(k+1)/(k-1)}$$

$$\frac{P}{P_0} = \left(1 + \frac{k-1}{2} \text{Ma}^2 \right)^{-k/(k-1)} \quad \frac{\rho}{\rho_0} = \left(1 + \frac{k-1}{2} \text{Ma}^2 \right)^{-1/(k-1)}$$

Discussion The tabulated values are useful for quick calculations, but be careful – they apply only to one specific value of k , in this case $k = 1.667$.

17-140 Helium gas is accelerated in a nozzle isentropically. For a specified mass flow rate, the throat and exit areas of the nozzle are to be determined.

Assumptions 1 Helium is an ideal gas with constant specific heats. 2 Flow through the nozzle is steady, one-dimensional, and isentropic. 3 The nozzle is adiabatic.

Properties The properties of helium are $R = 2.0769 \text{ kJ/kg}\cdot\text{K}$, $c_p = 5.1926 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.667$.

Analysis The inlet stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible,

$$\begin{aligned} T_{01} &= T_1 = 500 \text{ K} \\ P_{01} &= P_1 = 1.0 \text{ MPa} \end{aligned}$$

The flow is assumed to be isentropic, thus the stagnation temperature and pressure remain constant throughout the nozzle,

$$\begin{aligned} T_{02} &= T_{01} = 500 \text{ K} \\ P_{02} &= P_{01} = 1.0 \text{ MPa} \end{aligned}$$

The critical pressure and temperature are determined from

$$T^* = T_0 \left(\frac{2}{k+1} \right) = (500 \text{ K}) \left(\frac{2}{1.667+1} \right) = 375.0 \text{ K}$$

$$P^* = P_0 \left(\frac{2}{k+1} \right)^{k/(k-1)} = (1.0 \text{ MPa}) \left(\frac{2}{1.667+1} \right)^{1.667/(1.667-1)} = 0.487 \text{ MPa}$$

$$\rho^* = \frac{P^*}{RT^*} = \frac{487 \text{ kPa}}{(2.0769 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(375 \text{ K})} = 0.625 \text{ kg/m}^3$$

$$V^* = c^* = \sqrt{kRT^*} = \sqrt{(1.667)(2.0769 \text{ kJ/kg}\cdot\text{K})(375 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 1139.4 \text{ m/s}$$

Thus the throat area is

$$A^* = \frac{\dot{m}}{\rho^* V^*} = \frac{0.46 \text{ kg/s}}{(0.625 \text{ kg/m}^3)(1139.4 \text{ m/s})} = 6.460 \times 10^{-4} \text{ m}^2 = \mathbf{6.46 \text{ cm}^2}$$

At the nozzle exit the pressure is $P_2 = 0.1 \text{ MPa}$. Then the other properties at the nozzle exit are determined to be

$$\frac{P_0}{P_2} = \left(1 + \frac{k-1}{2} \text{Ma}_2^2 \right)^{k/(k-1)} \longrightarrow \frac{1.0 \text{ MPa}}{0.1 \text{ MPa}} = \left(1 + \frac{1.667-1}{2} \text{Ma}_2^2 \right)^{1.667/0.667}$$

It yields $\text{Ma}_2 = 2.130$, which is greater than 1. Therefore, the nozzle must be converging-diverging.

$$T_2 = T_0 \left(\frac{2}{2+(k-1)\text{Ma}_2^2} \right) = (500 \text{ K}) \left(\frac{2}{2+(1.667-1) \times 2.13^2} \right) = 199.0 \text{ K}$$

$$\rho_2 = \frac{P_2}{RT_2} = \frac{100 \text{ kPa}}{(2.0769 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(199 \text{ K})} = 0.242 \text{ kg/m}^3$$

$$V_2 = \text{Ma}_2 c_2 = \text{Ma}_2 \sqrt{kRT_2} = (2.13) \sqrt{(1.667)(2.0769 \text{ kJ/kg}\cdot\text{K})(199 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 1768.0 \text{ m/s}$$

Thus the exit area is

$$A_2 = \frac{\dot{m}}{\rho_2 V_2} = \frac{0.46 \text{ kg/s}}{(0.242 \text{ kg/m}^3)(1768 \text{ m/s})} = 0.1075 \times 10^{-3} \text{ m}^2 \cong \mathbf{10.8 \text{ cm}^2}$$

Discussion Flow areas in actual nozzles would be somewhat larger to accommodate the irreversibilities.

17-141 Using the normal shock relations, the normal shock functions are to be evaluated and tabulated as in Table A-33 for air.

Properties The specific heat ratio is given to be $k = 1.4$ for air.

Analysis The normal shock relations listed below are expressed in EES and the results are tabulated.

$$Ma_2 = \sqrt{\frac{(k-1)Ma_1^2 + 2}{2kMa_1^2 - k + 1}}$$

$$\frac{P_2}{P_1} = \frac{1 + kMa_1^2}{1 + kMa_2^2} = \frac{2kMa_1^2 - k + 1}{k + 1}$$

$$\frac{T_2}{T_1} = \frac{2 + Ma_1^2(k-1)}{2 + Ma_2^2(k-1)}$$

$$\frac{\rho_2}{\rho_1} = \frac{P_2 / P_1}{T_2 / T_1} = \frac{(k+1)Ma_1^2}{2 + (k-1)Ma_1^2} = \frac{V_1}{V_2}$$

$$\frac{P_{02}}{P_{01}} = \frac{Ma_1}{Ma_2} \left[\frac{1 + Ma_2^2(k-1)/2}{1 + Ma_1^2(k-1)/2} \right]^{\frac{k+1}{2(k-1)}}$$

$$\frac{P_{02}}{P_1} = \frac{(1 + kMa_1^2)[1 + Ma_2^2(k-1)/2]^{k/(k-1)}}{1 + kMa_2^2}$$

Air:

$$k=1.4$$

$$My = \text{SQRT}((Mx^2 + 2/(k-1))/(2*Mx^2*k/(k-1) - 1))$$

$$PyPx = (1 + k*Mx^2)/(1 + k*My^2)$$

$$TyTx = (1 + Mx^2*(k-1)/2)/(1 + My^2*(k-1)/2)$$

$$RyRx = PyPx/TyTx$$

$$P0yP0x = (Mx/My)*((1 + My^2*(k-1)/2)/(1 + Mx^2*(k-1)/2))^{0.5*(k+1)/(k-1)}$$

$$P0yPx = (1 + k*Mx^2)*(1 + My^2*(k-1)/2)^{k/(k-1)}/(1 + k*My^2)$$

Discussion The tabulated values are useful for quick calculations, but be careful – they apply only to one specific value of k , in this case $k = 1.3$.

17-143 Air flowing at a subsonic velocity in a duct is accelerated by heating. The highest rate of heat transfer without affecting the inlet conditions is to be determined.

Assumptions 1 The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid. 2 Inlet conditions (and thus the mass flow rate) remain constant.

Properties We take the properties of air to be $k = 1.4$, $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, and $R = 0.287 \text{ kJ/kg}\cdot\text{K}$.

Analysis Heat transfer will stop when the flow is choked, and thus $\text{Ma}_2 = V_2/c_2 = 1$. The inlet density and stagnation temperature are

$$\rho_1 = \frac{P_1}{RT_1} = \frac{350 \text{ kPa}}{(0.287 \text{ kJ/kg}\cdot\text{K})(420 \text{ K})} = 2.904 \text{ kg/m}^3$$

$$T_{01} = T_1 \left(1 + \frac{k-1}{2} \text{Ma}_1^2 \right) = (420 \text{ K}) \left(1 + \frac{1.4-1}{2} 0.6^2 \right) = 450.2 \text{ K}$$

Then the inlet velocity and the mass flow rate become

$$c_1 = \sqrt{kRT_1} = \sqrt{(1.4)(0.287 \text{ kJ/kg}\cdot\text{K})(420 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 410.8 \text{ m/s}$$

$$V_1 = \text{Ma}_1 c_1 = 0.6(410.8 \text{ m/s}) = 246.5 \text{ m/s}$$

$$\dot{m}_{\text{air}} = \rho_1 A_{\text{cl}} V_1 = (2.904 \text{ kg/m}^3)(0.1 \times 0.1 \text{ m}^2)(246.5 \text{ m/s}) = 7.157 \text{ kg/s}$$

The Rayleigh flow functions corresponding to the inlet and exit Mach numbers are $T_{02}/T_0^* = 1$ (since $\text{Ma}_2 = 1$).

$$\frac{T_{01}}{T_0^*} = \frac{(k+1)\text{Ma}_1^2 [2 + (k-1)\text{Ma}_1^2]}{(1+k\text{Ma}_1^2)^2} = \frac{(1.4+1)0.6^2 [2 + (1.4-1)0.6^2]}{(1+1.4 \times 0.6^2)^2} = 0.8189$$

Therefore,

$$\frac{T_{02}}{T_{01}} = \frac{T_{02}/T_0^*}{T_{01}/T_0^*} = \frac{1}{0.8189} \quad \rightarrow \quad T_{02} = T_{01}/0.8189 = (450.2 \text{ K})/0.8189 = 549.8 \text{ K}$$

Then the rate of heat transfer becomes

$$\dot{Q} = \dot{m}_{\text{air}} c_p (T_{02} - T_{01}) = (7.157 \text{ kg/s})(1.005 \text{ kJ/kg}\cdot\text{K})(549.8 - 450.2) \text{ K} = \mathbf{716 \text{ kW}}$$

Discussion It can also be shown that $T_2 = 458 \text{ K}$, which is the highest thermodynamic temperature that can be attained under stated conditions. If more heat is transferred, the additional temperature rise will cause the mass flow rate to decrease. We can also solve this problem using the Rayleigh function values listed in Table A-34.

17-144 Helium flowing at a subsonic velocity in a duct is accelerated by heating. The highest rate of heat transfer without affecting the inlet conditions is to be determined.

Assumptions 1 The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid. 2 Inlet conditions (and thus the mass flow rate) remain constant.

Properties We take the properties of helium to be $k = 1.667$, $c_p = 5.193 \text{ kJ/kg}\cdot\text{K}$, and $R = 2.077 \text{ kJ/kg}\cdot\text{K}$.

Analysis Heat transfer will stop when the flow is choked, and thus $\text{Ma}_2 = V_2/c_2 = 1$. The inlet density and stagnation temperature are

$$\rho_1 = \frac{P_1}{RT_1} = \frac{350 \text{ kPa}}{(2.077 \text{ kJ/kg}\cdot\text{K})(420 \text{ K})} = 0.4012 \text{ kg/m}^3$$

$$T_{01} = T_1 \left(1 + \frac{k-1}{2} \text{Ma}_1^2 \right) = (420 \text{ K}) \left(1 + \frac{1.667-1}{2} 0.6^2 \right) = 470.4 \text{ K}$$

Then the inlet velocity and the mass flow rate become

$$c_1 = \sqrt{kRT_1} = \sqrt{(1.667)(2.077 \text{ kJ/kg}\cdot\text{K})(420 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 1206 \text{ m/s}$$

$$V_1 = \text{Ma}_1 c_1 = 0.6(1206 \text{ m/s}) = 723.5 \text{ m/s}$$

$$\dot{m}_{\text{air}} = \rho_1 A_{\text{cl}} V_1 = (0.4012 \text{ kg/m}^3)(0.1 \times 0.1 \text{ m}^2)(723.5 \text{ m/s}) = 2.903 \text{ kg/s}$$

The Rayleigh flow functions corresponding to the inlet and exit Mach numbers are $T_{02}/T_0^* = 1$ (since $\text{Ma}_2 = 1$)

$$\frac{T_{01}}{T_0^*} = \frac{(k+1)\text{Ma}_1^2 [2 + (k-1)\text{Ma}_1^2]}{(1+k\text{Ma}_1^2)^2} = \frac{(1.667+1)0.6^2 [2 + (1.667-1)0.6^2]}{(1+1.667 \times 0.6^2)^2} = 0.8400$$

Therefore,

$$\frac{T_{02}}{T_{01}} = \frac{T_{02}/T_0^*}{T_{01}/T_0^*} = \frac{1}{0.8400} \quad \rightarrow \quad T_{02} = T_{01} / 0.8400 = (470.4 \text{ K}) / 0.8400 = 560.0 \text{ K}$$

Then the rate of heat transfer becomes

$$\dot{Q} = \dot{m}_{\text{air}} c_p (T_{02} - T_{01}) = (2.903 \text{ kg/s})(5.193 \text{ kJ/kg}\cdot\text{K})(560.0 - 470.4) \text{ K} = \mathbf{1350 \text{ kW}}$$

Discussion It can also be shown that $T_2 = 420 \text{ K}$, which is the highest thermodynamic temperature that can be attained under stated conditions. If more heat is transferred, the additional temperature rise will cause the mass flow rate to decrease. Also, in the solution of this problem, we cannot use the values of Table A-34 since they are based on $k = 1.4$.

17-145 Air flowing at a subsonic velocity in a duct is accelerated by heating. For a specified exit Mach number, the heat transfer for a specified exit Mach number as well as the maximum heat transfer are to be determined.

Assumptions 1 The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid. 2 Inlet conditions (and thus the mass flow rate) remain constant.

Properties We take the properties of air to be $k = 1.4$, $c_p = 1.005$ kJ/kg·K, and $R = 0.287$ kJ/kg·K.

Analysis The inlet Mach number and stagnation temperature are

$$c_1 = \sqrt{kRT_1} = \sqrt{(1.4)(0.287 \text{ kJ/kg} \cdot \text{K})(400 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 400.9 \text{ m/s}$$

$$\text{Ma}_1 = \frac{V_1}{c_1} = \frac{100 \text{ m/s}}{400.9 \text{ m/s}} = 0.2494$$

$$T_{01} = T_1 \left(1 + \frac{k-1}{2} \text{Ma}_1^2 \right) = (400 \text{ K}) \left(1 + \frac{1.4-1}{2} 0.2494^2 \right) = 405.0 \text{ K}$$

The Rayleigh flow functions corresponding to the inlet and exit Mach numbers are (Table A-34):

$$\text{Ma}_1 = 0.2494: \quad T_{01}/T^* = 0.2559$$

$$\text{Ma}_2 = 0.8: \quad T_{02}/T^* = 0.9639$$

Then the exit stagnation temperature and the heat transfer are determined to be

$$\frac{T_{02}}{T_{01}} = \frac{T_{02}/T^*}{T_{01}/T^*} = \frac{0.9639}{0.2559} = 3.7667 \quad \rightarrow \quad T_{02} = 3.7667 T_{01} = 3.7667(405.0 \text{ K}) = 1526 \text{ K}$$

$$q = c_p (T_{02} - T_{01}) = (1.005 \text{ kJ/kg} \cdot \text{K})(1526 - 405) \text{ K} = 1126 \text{ kJ/kg} \cong \mathbf{1130 \text{ kJ/kg}}$$

Maximum heat transfer will occur when the flow is choked, and thus $\text{Ma}_2 = 1$ and thus $T_{02}/T^* = 1$. Then,

$$\frac{T_{02}}{T_{01}} = \frac{T_{02}/T^*}{T_{01}/T^*} = \frac{1}{0.2559} \quad \rightarrow \quad T_{02} = T_{01} / 0.2559 = (405 \text{ K}) / 0.2559 = 1583 \text{ K}$$

$$q_{\max} = c_p (T_{02} - T_{01}) = (1.005 \text{ kJ/kg} \cdot \text{K})(1583 - 405) \text{ K} = 1184 \text{ kJ/kg} \cong \mathbf{1180 \text{ kJ/kg}}$$

Discussion This is the maximum heat that can be transferred to the gas without affecting the mass flow rate. If more heat is transferred, the additional temperature rise will cause the mass flow rate to decrease.

17-146 Air flowing at sonic conditions in a duct is accelerated by cooling. For a specified exit Mach number, the amount of heat transfer per unit mass is to be determined.

Assumptions The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid.

Properties We take the properties of air to be $k = 1.4$, $c_p = 1.005 \text{ kJ/kg}\cdot\text{K}$, and $R = 0.287 \text{ kJ/kg}\cdot\text{K}$.

Analysis Noting that $\text{Ma}_1 = 1$, the inlet stagnation temperature is

$$T_{01} = T_1 \left(1 + \frac{k-1}{2} \text{Ma}_1^2 \right) = (340 \text{ K}) \left(1 + \frac{1.4-1}{2} 1^2 \right) = 408 \text{ K}$$

The Rayleigh flow functions T_0/T_0^* corresponding to the inlet and exit Mach numbers are (Table A-34):

$$\text{Ma}_1 = 1: \quad T_{01}/T_0^* = 1$$

$$\text{Ma}_2 = 1.6: \quad T_{02}/T_0^* = 0.8842$$

Then the exit stagnation temperature and heat transfer are determined to be

$$\frac{T_{02}}{T_{01}} = \frac{T_{02}/T_0^*}{T_{01}/T_0^*} = \frac{0.8842}{1} = 0.8842 \quad \rightarrow \quad T_{02} = 0.8842 T_{01} = 0.8842(408 \text{ K}) = 360.75 \text{ K}$$

$$q = c_p (T_{02} - T_{01}) = (1.005 \text{ kJ/kg}\cdot\text{K})(360.75 - 408) \text{ K} = -47.49 \text{ kJ/kg} \cong \mathbf{-47.5 \text{ kJ/kg}}$$

Discussion The negative sign confirms that the gas needs to be cooled in order to be accelerated.

17-147 Air flowing at a supersonic velocity in a duct is accelerated by cooling. For a specified exit Mach number, the rate of heat transfer is to be determined.

Assumptions The assumptions associated with Rayleigh flow (i.e., steady one-dimensional flow of an ideal gas with constant properties through a constant cross-sectional area duct with negligible frictional effects) are valid.

Properties We take the properties of air to be $k = 1.4$, $c_p = 1.005$ kJ/kg·K, and $R = 0.287$ kJ/kg·K.

Analysis Knowing stagnation properties, the static properties are determined to be

$$T_1 = T_{01} \left(1 + \frac{k-1}{2} \text{Ma}_1^2 \right)^{-1} = (350 \text{ K}) \left(1 + \frac{1.4-1}{2} 1.2^2 \right)^{-1} = 271.7 \text{ K}$$

$$P_1 = P_{01} \left(1 + \frac{k-1}{2} \text{Ma}_1^2 \right)^{-k/(k-1)} = (240 \text{ kPa}) \left(1 + \frac{1.4-1}{2} 1.2^2 \right)^{-1.4/0.4} = 98.97 \text{ kPa}$$

$$\rho_1 = \frac{P_1}{RT_1} = \frac{98.97 \text{ kPa}}{(0.287 \text{ kJ/kgK})(271.7 \text{ K})} = 1.269 \text{ kg/m}^3$$

Then the inlet velocity and the mass flow rate become

$$c_1 = \sqrt{kRT_1} = \sqrt{(1.4)(0.287 \text{ kJ/kg} \cdot \text{K})(271.7 \text{ K}) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 330.4 \text{ m/s}$$

$$V_1 = \text{Ma}_1 c_1 = 1.2(330.4 \text{ m/s}) = 396.5 \text{ m/s}$$

$$\dot{m}_{\text{air}} = \rho_1 A_c V_1 = (1.269 \text{ kg/m}^3) [\pi(0.20 \text{ m})^2 / 4] (396.5 \text{ m/s}) = 15.81 \text{ kg/s}$$

The Rayleigh flow functions T_0/T_0^* corresponding to the inlet and exit Mach numbers are (Table A-34):

$$\text{Ma}_1 = 1.2: \quad T_{01}/T_0^* = 0.9787$$

$$\text{Ma}_2 = 2: \quad T_{02}/T_0^* = 0.7934$$

Then the exit stagnation temperature is determined to be

$$\frac{T_{02}}{T_{01}} = \frac{T_{02}/T_0^*}{T_{01}/T_0^*} = \frac{0.7934}{0.9787} = 0.8107 \quad \rightarrow \quad T_{02} = 0.8107 T_{01} = 0.8107(350 \text{ K}) = 283.7 \text{ K}$$

Finally, the rate of heat transfer is

$$\dot{Q} = \dot{m}_{\text{air}} c_p (T_{02} - T_{01}) = (15.81 \text{ kg/s})(1.005 \text{ kJ/kg} \cdot \text{K})(283.7 - 350) \text{ K} = -1053 \text{ kW} \cong \mathbf{-1050 \text{ kW}}$$

Discussion The negative sign confirms that the gas needs to be cooled in order to be accelerated. Also, it can be shown that the thermodynamic temperature drops to 158 K at the exit, which is extremely low. Therefore, the duct may need to be heavily insulated to maintain indicated flow conditions.

17-148 Saturated steam enters a converging-diverging nozzle with a low velocity. The throat area, exit velocity, mass flow rate, and exit Mach number are to be determined for isentropic and 90 percent efficient nozzle cases.

Assumptions 1 Flow through the nozzle is steady and one-dimensional.
2 The nozzle is adiabatic.

Analysis (a) The inlet stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible. Thus $h_{10} = h_1$. At the inlet,

$$h_1 = (h_f + x_1 h_{fg})_{@1.75 \text{ MPa}} = 878.16 + 0.90 \times 1917.1 = 2603.5 \text{ kJ/kg}$$

$$s_1 = (s_f + x_1 s_{fg})_{@1.75 \text{ MPa}} = 2.3844 + 0.90 \times 4.0033 = 5.9874 \text{ kJ/kg} \cdot \text{K}$$

At the exit, $P_2 = 1.2 \text{ MPa}$ and $s_2 = s_{2s} = s_1 = 5.9874 \text{ kJ/kg} \cdot \text{K}$. Thus,

$$s_2 = s_f + x_2 s_{fg} \rightarrow 5.9874 = 2.2159 + x_2(4.3058) \rightarrow x_2 = 0.8759$$

$$h_2 = h_f + x_2 h_{fg} = 798.33 + 0.8759 \times 1985.4 = 2537.4 \text{ kJ/kg}$$

$$\nu_2 = \nu_f + x_2 \nu_{fg} = 0.001138 + 0.8759 \times (0.16326 - 0.001138) = 0.14314 \text{ m}^3/\text{kg}$$

Then the exit velocity is determined from the steady-flow energy balance to be

$$h_1 + \frac{V_1^2}{2} = h_2 + \frac{V_2^2}{2} \rightarrow 0 = h_2 - h_1 + \frac{V_2^2 - V_1^2}{2}$$

Solving for V_2 ,

$$V_2 = \sqrt{2(h_1 - h_2)} = \sqrt{2(2603.5 - 2537.4) \text{ kJ/kg} \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = \mathbf{363.7 \text{ m/s}}$$

The mass flow rate is determined from

$$\dot{m} = \frac{1}{\nu_2} A_2 V_2 = \frac{1}{0.14314 \text{ m}^3/\text{kg}} (25 \times 10^{-4} \text{ m}^2)(363.7 \text{ m/s}) = \mathbf{6.35 \text{ kg/s}}$$

The velocity of sound at the exit of the nozzle is determined from

$$c = \left(\frac{\partial P}{\partial \nu} \right)_s^{1/2} \cong \left(\frac{\Delta P}{\Delta(1/\nu)} \right)_s^{1/2}$$

The specific volume of steam at $s_2 = 5.9874 \text{ kJ/kg} \cdot \text{K}$ and at pressures just below and just above the specified pressure (1.1 and 1.3 MPa) are determined to be 0.1547 and 0.1333 m^3/kg . Substituting,

$$c_2 = \sqrt{\left(\frac{1300 - 1100 \text{ kPa}}{0.1333 - 0.1547} \right) \text{ kg/m}^3 \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kPa} \cdot \text{m}^3} \right)} = 438.9 \text{ m/s}$$

Then the exit Mach number becomes

$$\text{Ma}_2 = \frac{V_2}{c_2} = \frac{363.7 \text{ m/s}}{438.9 \text{ m/s}} = \mathbf{0.829}$$

The steam is saturated, and thus the critical pressure which occurs at the throat is taken to be

$$P_t = P^* = 0.576 \times P_{01} = 0.576 \times 1.75 = 1.008 \text{ MPa}$$

Then at the throat,

$$P_t = 1.008 \text{ MPa} \text{ and } s_t = s_1 = 5.9874 \text{ kJ/kg} \cdot \text{K}$$

Thus,

$$h_t = 2507.7 \text{ kJ/kg}$$

$$v_t = 0.1672 \text{ m}^3/\text{kg}$$

Then the throat velocity is determined from the steady-flow energy balance,

$$h_1 + \frac{V_1^2}{2} = h_t + \frac{V_t^2}{2} \rightarrow 0 = h_t - h_1 + \frac{V_t^2}{2}$$

Solving for V_t ,

$$V_t = \sqrt{2(h_1 - h_t)} = \sqrt{2(2603.5 - 2507.7) \text{ kJ/kg} \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = 437.7 \text{ m/s}$$

Thus the throat area is

$$A_t = \frac{\dot{m} v_t}{V_t} = \frac{(6.35 \text{ kg/s})(0.1672 \text{ m}^3/\text{kg})}{437.7 \text{ m/s}} = 24.26 \times 10^{-4} \text{ m}^2 = \mathbf{24.26 \text{ cm}^2}$$

(b) The inlet stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible. Thus $h_{10} = h_1$. At the inlet,

$$h_1 = (h_f + x_1 h_{fg})_{@1.75 \text{ MPa}} = 878.16 + 0.90 \times 1917.1 = 2603.5 \text{ kJ/kg}$$

$$s_1 = (s_f + x_1 s_{fg})_{@1.75 \text{ MPa}} = 2.3844 + 0.90 \times 4.0033 = 5.9874 \text{ kJ/kg} \cdot \text{K}$$

At state 2s, $P_2 = 1.2 \text{ MPa}$ and $s_2 = s_{2s} = s_1 = 5.9874 \text{ kJ/kg} \cdot \text{K}$. Thus,

$$s_{2s} = s_f + x_2 s_{fg} \rightarrow 5.9874 = 2.2159 + x_2(4.3058) \rightarrow x_{2s} = 0.8759$$

$$h_{2s} = h_f + x_2 h_{fg} = 798.33 + 0.8759 \times 1985.4 = 2537.4 \text{ kJ/kg}$$

The enthalpy of steam at the actual exit state is determined from

$$\eta_N = \frac{h_{01} - h_2}{h_{01} - h_{2s}} \rightarrow 0.92 = \frac{2603.5 - h_2}{2603.5 - 2537.4} \rightarrow h_2 = 2542.7 \text{ kJ/kg}$$

Therefore at the exit, $P_2 = 1.2 \text{ MPa}$ and $h_2 = 2542.7 \text{ kJ/kg} \cdot \text{K}$. Thus,

$$h_2 = h_f + x_2 h_{fg} \rightarrow 2542.7 = 798.33 + x_2(1985.4) \rightarrow x_2 = 0.8786$$

$$s_2 = s_f + x_2 s_{fg} = 2.2159 + 0.8786 \times 4.3058 = 5.9989$$

$$v_2 = v_f + x_2 v_{fg} = 0.001138 + 0.8786 \times (0.16326 - 0.001138) = 0.1436 \text{ m}^3/\text{kg}$$

Then the exit velocity is determined from the steady-flow energy balance to be

$$h_1 + \frac{V_1^2}{2} = h_2 + \frac{V_2^2}{2} \rightarrow 0 = h_2 - h_1 + \frac{V_2^2 - V_1^2}{2}$$

Solving for V_2 ,

$$V_2 = \sqrt{2(h_1 - h_2)} = \sqrt{2(2603.5 - 2542.7) \text{ kJ/kg} \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)} = \mathbf{348.9 \text{ m/s}}$$

The mass flow rate is determined from

$$\dot{m} = \frac{1}{v_2} A_2 V_2 = \frac{1}{0.1436 \text{ m}^3/\text{kg}} (25 \times 10^{-4} \text{ m}^2)(348.9 \text{ m/s}) = \mathbf{6.07 \text{ kg/s}}$$

The velocity of sound at the exit of the nozzle is determined from

$$c = \left(\frac{\partial \mathcal{P}}{\partial \rho} \right)_s \cong \left(\frac{\Delta \mathcal{P}}{\Delta(1/v)} \right)_s^{1/2}$$

The specific volume of steam at $s_2 = 5.9989$ kJ/kg·K and at pressures just below and just above the specified pressure (1.1 and 1.3 MPa) are determined to be 0.1551 and 0.1337 m³/kg. Substituting,

$$c_2 = \sqrt{\frac{(1300 - 1100) \text{ kPa}}{\left(\frac{1}{0.1337} - \frac{1}{0.1551}\right) \text{ kg/m}^3} \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kPa} \cdot \text{m}^3}\right)} = 439.7 \text{ m/s}$$

Then the exit Mach number becomes

$$\text{Ma}_2 = \frac{V_2}{c_2} = \frac{348.9 \text{ m/s}}{439.7 \text{ m/s}} = \mathbf{0.793}$$

The steam is saturated, and thus the critical pressure which occurs at the throat is taken to be

$$P_t = P^* = 0.576 \times P_{01} = 0.576 \times 1.75 = 1.008 \text{ MPa}$$

At state 2ts, $P_{ts} = 1.008$ MPa and $s_{ts} = s_1 = 5.9874$ kJ/kg·K. Thus, $h_{ts} = 2507.7$ kJ/kg.

The actual enthalpy of steam at the throat is

$$\eta_N = \frac{h_{01} - h_t}{h_{01} - h_{ts}} \rightarrow 0.92 = \frac{2603.5 - h_t}{2603.5 - 2507.7} \rightarrow h_t = 2515.4 \text{ kJ/kg}$$

Therefore at the throat, $P_2 = 1.008$ MPa and $h_t = 2515.4$ kJ/kg. Thus, $v_t = 0.1679$ m³/kg.

Then the throat velocity is determined from the steady-flow energy balance,

$$h_1 + \frac{V_1^2}{2} = h_t + \frac{V_t^2}{2} \rightarrow 0 = h_t - h_1 + \frac{V_t^2}{2}$$

Solving for V_t ,

$$V_t = \sqrt{2(h_1 - h_t)} = \sqrt{2(2603.5 - 2515.4) \text{ kJ/kg} \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}}\right)} = 419.9 \text{ m/s}$$

Thus the throat area is

$$A_t = \frac{\dot{m} v_t}{V_t} = \frac{(6.07 \text{ kg/s})(0.1679 \text{ m}^3/\text{kg})}{419.9 \text{ m/s}} = 24.30 \times 10^{-4} \text{ m}^2 = \mathbf{24.30 \text{ cm}^2}$$

17-149 Using EES (or other) software, the shape of a converging-diverging nozzle is to be determined for specified flow rate and stagnation conditions. The nozzle and the Mach number are to be plotted.

Assumptions 1 Air is an ideal gas with constant specific heats. 2 Flow through the nozzle is steady, one-dimensional, and isentropic. 3 The nozzle is adiabatic.

Properties The specific heat ratio of air at room temperature is 1.4.

Analysis The problem is solved using EES, and the results are tabulated and plotted below.

```

k=1.4
Cp=1.005 "kJ/kg.K"
R=0.287 "kJ/kg.K"
P0=1400 "kPa"
T0=200+273 "K"
m=3 "kg/s"
rho_0=P0/(R*T0)
rho=P/(R*T)
T=T0*(P/P0)^((k-1)/k)
V=SQRT(2*Cp*(T0-T)*1000)
A=m/(rho*V)*10000 "cm2"
C=SQRT(k*R*T*1000)
Ma=V/C
    
```

Pressure <i>P</i> , kPa	Flow area <i>A</i> , cm ²	Mach number <i>Ma</i>
1400	∞	0
1350	30.1	0.229
1300	21.7	0.327
1250	18.1	0.406
1200	16.0	0.475
1150	14.7	0.538
1100	13.7	0.597
1050	13.0	0.655
1000	12.5	0.710

900	11.9	0.820
850	11.7	0.876
800	11.6	0.931
750	11.5	0.988
700	11.5	1.047
650	11.6	1.107
600	11.8	1.171
550	12.0	1.237
500	12.3	1.308
450	12.8	1.384
400	13.3	1.467
350	14.0	1.559
300	15.0	1.663
250	16.4	1.784
200	18.3	1.929
150	21.4	2.114
100	27.0	2.373

Discussion The shape is not actually to scale since the horizontal axis is pressure rather than distance. If the pressure decreases linearly with distance, then the shape *would* be to scale.

17-150 Steam enters a converging nozzle. The exit pressure, the exit velocity, and the mass flow rate versus the back pressure for a specified back pressure range are to be plotted.

Assumptions 1 Steam is to be treated as an ideal gas with constant specific heats. 2 Flow through the nozzle is steady, one-dimensional, and isentropic. 3 The nozzle is adiabatic.

Properties The ideal gas properties of steam are $R = 0.462 \text{ kJ/kg}\cdot\text{K}$, $c_p = 1.872 \text{ kJ/kg}\cdot\text{K}$, and $k = 1.3$.

Analysis We use EES to solve the problem. The stagnation properties in this case are identical to the inlet properties since the inlet velocity is negligible. Since the flow is isentropic, they remain constant throughout the nozzle,

$$P_0 = P_i = 6 \text{ MPa} \quad \text{and} \quad T_0 = T_i = 700 \text{ K}$$

The critical pressure is determined to be

$$P^* = P_0 \left(\frac{2}{k+1} \right)^{k/(k-1)} = (6 \text{ MPa}) \left(\frac{2}{1.3+1} \right)^{1.3/0.3} = 3.274 \text{ MPa}$$

Then the pressure at the exit plane (throat) is

$$P_e = P_b \quad \text{for} \quad P_b \geq 3.274 \text{ MPa}$$

$$P_e = P^* = 3.274 \text{ MPa} \quad \text{for} \quad P_b < 3.274 \text{ MPa} \quad (\text{choked flow})$$

Thus the back pressure does not affect the flow when $3 < P_b < 3.274$ MPa. For a specified exit pressure P_e , the temperature, velocity, and mass flow rate are

$$\text{Temperature} \quad T_e = T_0 \left(\frac{P_e}{P_0} \right)^{(k-1)/k} = (700 \text{ K}) \left(\frac{P_e}{6} \right)^{0.3/1.3}$$

$$\text{Velocity} \quad V = \sqrt{2c_p(T_0 - T_e)} = \sqrt{2(1.872 \text{ kJ/kg}\cdot\text{K})(700 - T_e) \left(\frac{1000 \text{ m}^2/\text{s}^2}{1 \text{ kJ/kg}} \right)}$$

$$\text{Density} \quad \rho_e = \frac{P_e}{RT_e} = \frac{P_e}{(0.462 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})T_e}$$

$$\text{Mass flow rate} \quad \dot{m} = \rho_e V_e A_e = \rho_e V_e (0.0008 \text{ m}^2)$$

The results of the calculations are tabulated as follows:

P_b , MPa	P_e , MPa	T_e , K	V_e , m/s	ρ_e , kg/m ³	\dot{m} , kg/s
6.0	6.0	700	0	18.55	0
5.5	5.5	686.1	228.1	17.35	3.166
5.0	5.0	671.2	328.4	16.12	4.235
4.5	4.5	655.0	410.5	14.87	4.883
4.0	4.0	637.5	483.7	13.58	5.255
3.5	3.5	618.1	553.7	12.26	5.431
3.274	3.274	608.7	584.7	11.64	5.445
3.0	3.274	608.7	584.7	11.64	5.445

Discussion Once the back pressure drops below 3.274 MPa, the flow is choked, and \dot{m} remains constant from then on.

17-151 An expression for the ratio of the stagnation pressure after a shock wave to the static pressure before the shock wave as a function of k and the Mach number upstream of the shock wave is to be found.

Analysis The relation between P_1 and P_2 is

$$\frac{P_2}{P_1} = \frac{1 + k\text{Ma}_2^2}{1 + k\text{Ma}_1^2} \longrightarrow P_2 = P_1 \left(\frac{1 + k\text{Ma}_1^2}{1 + k\text{Ma}_2^2} \right)$$

We substitute this into the isentropic relation

$$\frac{P_{02}}{P_2} = \left(1 + (k-1)\text{Ma}_2^2 / 2 \right)^{k/(k-1)}$$

which yields

$$\frac{P_{02}}{P_1} = \left(\frac{1 + k\text{Ma}_1^2}{1 + k\text{Ma}_2^2} \right) \left(1 + (k-1)\text{Ma}_2^2 / 2 \right)^{k/(k-1)}$$

where

$$\text{Ma}_2^2 = \frac{\text{Ma}_1^2 + 2/(k-1)}{2k\text{Ma}_1^2/(k-1) - 1}$$

Substituting,

$$\boxed{\frac{P_{02}}{P_1} = \left(\frac{(1 + k\text{Ma}_1^2)(2k\text{Ma}_1^2 - k + 1)}{k\text{Ma}_1^2(k+1) - k + 3} \right) \left(1 + \frac{(k-1)\text{Ma}_1^2 / 2 + 1}{2k\text{Ma}_1^2/(k-1) - 1} \right)^{k/(k-1)}}$$

Discussion Similar manipulations of the equations can be performed to get the ratio of other parameters across a shock.

17-152 Using the compressible flow relations, the one-dimensional compressible flow functions are to be evaluated and tabulated as in Table A-32 for air.

Properties The specific heat ratio is given to be $k = 1.4$ for air.

Analysis The compressible flow functions listed below are expressed in EES and the results are tabulated.

$$\text{Ma}^* = \text{Ma} \sqrt{\frac{k+1}{2+(k-1)\text{Ma}^2}} \quad \frac{A}{A^*} = \frac{1}{\text{Ma}} \left[\left(\frac{2}{k+1} \right) \left(1 + \frac{k-1}{2} \text{Ma}^2 \right) \right]^{0.5(k+1)/(k-1)}$$

$$\frac{P}{P_0} = \left(1 + \frac{k-1}{2} \text{Ma}^2 \right)^{-k/(k-1)} \quad \frac{\rho}{\rho_0} = \left(1 + \frac{k-1}{2} \text{Ma}^2 \right)^{-1/(k-1)}$$

$$\frac{T}{T_0} = \left(1 + \frac{k-1}{2} \text{Ma}^2 \right)^{-1}$$

Air:

```

k=1.4
PP0=(1+(k-1)*M^2/2)^(-k/(k-1))
TT0=1/(1+(k-1)*M^2/2)
DD0=(1+(k-1)*M^2/2)^(-1/(k-1))
Mcr=M*SQRT((k+1)/(2+(k-1)*M^2))
AAcr=((2/(k+1))*(1+0.5*(k-1)*M^2))^(0.5*(k+1)/(k-1))/M

```

Fundamentals of Engineering (FE) Exam Problems

17-154 An aircraft is cruising in still air at 5°C at a velocity of 400 m/s. The air temperature at the nose of the aircraft where stagnation occurs is

- (a) 5°C (b) 25°C (c) 55°C (d) 80°C (e) 85°C

Answer (e) 85°C

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
T1=5 [C]
Vel1= 400 [m/s]
k=1.4
Cp=1.005 [kJ/kg-K]
T1_stag=T1+Vel1^2/(2*Cp*1000)
```

"Some Wrong Solutions with Common Mistakes:"

```
W1_Tstag=T1 "Assuming temperature rise"
W2_Tstag=Vel1^2/(2*Cp*1000) "Using just the dynamic temperature"
W3_Tstag=T1+Vel1^2/(Cp*1000) "Not using the factor 2"
```

17-155 Air is flowing in a wind tunnel at 25°C, 80 kPa, and 250 m/s. The stagnation pressure at a probe inserted into the flow stream is

- (a) 87 kPa (b) 96 kPa (c) 113 kPa (d) 119 kPa (e) 125 kPa

Answer (c) 96 kPa

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
T1=(25+273) [K]
P1=80 [kPa]
Vel1= 250 [m/s]

k=1.4
Cp=1.005 [kJ/kg-K]
T1_stag=(T1+273)+Vel1^2/(2*Cp*1000)
T1_stag/(T1+273)=(P1_stag/P1)^((k-1)/k)
```

"Some Wrong Solutions with Common Mistakes:"

```
T11_stag/T1=(W1_P1stag/P1)^((k-1)/k); T11_stag=T1+Vel1^2/(2*Cp*1000) "Using deg. C for temperatures"
T12_stag/(T1+273)=(W2_P1stag/P1)^((k-1)/k); T12_stag=(T1+273)+Vel1^2/(Cp*1000) "Not using the factor 2"
T13_stag/(T1+273)=(W3_P1stag/P1)^(k-1); T13_stag=(T1+273)+Vel1^2/(2*Cp*1000) "Using wrong isentropic relation"
```

17-156 An aircraft is reported to be cruising in still air at -20°C and 40 kPa at a Mach number of 0.86. The velocity of the aircraft is

- (a) 91 m/s (b) 220 m/s (c) 186 m/s (d) 274 m/s (e) 378 m/s

Answer (d) 274 m/s

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
T1=(-20+273) [K]
P1=40 [kPa]
Mach=0.86
k=1.4
Cp=1.005 [kJ/kg-K]
R=0.287 [kJ/kg-K]

17-162 Consider gas flow through a converging-diverging nozzle. Of the five statements below, select the one that is incorrect:

- (a) The fluid velocity at the throat can never exceed the speed of sound.
 (b) If the fluid velocity at the throat is below the speed of sound, the diversion section will act like a diffuser.
 (c) If the fluid enters the diverging section with a Mach number greater than one, the flow at the nozzle exit will be supersonic.
 (d) There will be no flow through the nozzle if the back pressure equals the stagnation pressure.
 (e) The fluid velocity decreases, the entropy increases, and stagnation enthalpy remains constant during flow through a normal shock.

Answer (c) If the fluid enters the diverging section with a Mach number greater than one, the flow at the nozzle exit will be supersonic.

17-163 Combustion gases with $k = 1.33$ enter a converging nozzle at stagnation temperature and pressure of 350°C and 400 kPa, and are discharged into the atmospheric air at 20°C and 100 kPa. The lowest pressure that will occur within the nozzle is

- (a) 13 kPa (b) 100 kPa (c) 216 kPa (d) 290 kPa (e) 315 kPa

Answer (c) 216 kPa

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

Introduction

18-1C The concern over the depletion of fossil fuels and pollutant and greenhouse emissions associated by their combustion can be tackled by essentially two methods: (i) Using renewable energy sources to replace fossil fuels. (ii) Implementing energy efficiency practices in all aspects of energy production, distribution, and consumption so that less fuel is used while obtaining the same useful output.

18-2C Main renewable energy sources include *solar*, *wind*, *hydropower*, *geothermal*, and *biomass*. Ocean, wave, and tidal energies are also renewable sources but they are currently not economical and the technologies are still in the experimental stage.

18-3C Although solar energy is sufficient to meet the entire energy needs of the world, currently it is not economical to do so because of the *low concentration* of solar energy on earth and the *high capital cost* of harnessing it.

18-4C *Wind* is the fastest growing renewable. *Hydropower* represents the greatest amount of electricity production among renewable.

18-5C We do not agree. The electricity used by the electric cars is generated somewhere else mostly by burning fuel and thus emitting pollution. Therefore, each time an electric car consumes 1 kWh of electricity, it bears the responsibility for the pollution s emitted as 1 kWh of electricity (plus the conversion and transmission losses) is generated elsewhere. The electric cars can be claimed to be zero emission vehicles only when the electricity they consume is generated by emission-free renewable resources such as hydroelectric, solar, wind, and geothermal energy.

Solar Energy

18-6C The conversion of solar energy into other useful forms of energy can be accomplished by three conversion processes. These are *heliothermal* process, *heliothermal* process, and *helioelectrical* process.

18-7C Solar energy is converted to electricity directly in solar cells while it is first converted to thermal energy in heliostats. Heliostats are mirrors that reflect solar radiation into a single receiver. The resulting high temperature thermal energy is converted to electricity by a heat engine.

18-8C Solar energy can be used for cooling applications in summer by absorption cooling systems but they are complex devices involving high initial costs.

18-9C Solar radiation falls in ultraviolet, visible, and infrared regions of spectrum. Most radiation falls in near-infrared region.

18-10C When solar radiation strikes a surface, part of it is absorbed, part of it is reflected, and the remaining part, if any, is transmitted. The *transmissivity* τ , the *reflectivity* ρ , and the *absorptivity* α of a surface for solar energy are the fractions of incident solar radiation transmitted, reflected, and absorbed, respectively. For an opaque surface,

$$\tau = 0 \quad \text{and} \quad \alpha + \rho = 1$$

18-11C Most solar collectors in operation today are used to produce hot water.

18-12C A *thermosyphon solar water heater system* operates on a natural circulation. Water flows through the system when warm water rises into the tank as cooler water sinks. An *active, closed loop solar water heater* uses a pump for the circulation of water containing antifreeze fluid.

18-13C A solar hot water collector may be equipped with an *electric resistance heater* to provide hot water when solar energy is not available. A *backup water heater* that runs on natural gas or another fuel may also be used.

18-14C The efficiency of a flat-plate solar collector is given by

$$\eta_c = \tau\alpha - U \frac{T_c - T_a}{G}$$

The efficiency of a solar collector is maximized when the temperature difference between the collector temperature and the air temperature $T_c - T_a$ is zero. In this case, the efficiency is equal to $\tau\alpha$. An unglazed collector has the highest maximum efficiency as it has the highest value of $\tau\alpha$ values. This is followed by the single-glazing and double-glazing collectors.

18-15C The concentration of solar energy is low, and as a result, the temperature of hot water obtainable in a flat-plate collector is low (usually under 80°C). Hot fluid (water, steam, air, or another fluid) at much higher temperatures can be produced using concentrating collectors by concentrating solar radiation on a smaller area. Temperatures in the receiver of a concentrating collector can reach 400°C.

18-16C The efficiency of a solar system used to produce electricity may be defined as the power produced divided by the total solar irradiation. That is,

$$\eta_{\text{th,solar}} = \frac{\dot{W}_{\text{out}}}{\dot{Q}_{\text{incident}}} = \frac{\dot{W}_{\text{out}}}{A_c G}$$

where A_c is the collector surface area receiving solar irradiation and G is the solar irradiation.

18-17C A promising method of power generation involves collecting and storing solar energy in large artificial lakes a few meters deep, called *solar ponds*. Solar energy is absorbed by all parts of the pond, and the water temperature rises everywhere. The top part of the pond, however, loses to the atmosphere much of the heat it absorbs, and as a result, its temperature drops. This cool water serves as insulation for the bottom part of the pond and helps trap the energy there. Usually, salt is planted at the bottom of the pond to prevent the rise of this hot water to the top. A power plant that uses an organic fluid, such as alcohol, as the working fluid can be operated between the top and the bottom portions of the pond. The main disadvantage of solar pond power plant is the low thermal efficiency.

18-18C An *ocean thermal energy converter* (OTEC) system uses the same principle as a solar pond system but in this case the water at the sea or ocean surface is warmer as a result of solar energy absorption. The water at a deeper location is cooler. Then, a heat engine can be operated that utilizes the surface warm water as heat source and deep cold water as the heat sink. Experiments have been performed for OTEC principle but the results have not been promising due to large installation cost and low thermal efficiency.

18-19C The *current density* J is defined as the current I over the cell surface area A . The current density flow from n -type semiconductor to p -type semiconductor is denoted by J_r , and called the *light-induced recombination current* and that from p -type to n -type is denoted by J_o , and called the *dark current* or *reverse saturation current*.

18-20C A photovoltaic system typically consists *arrays*, which are obtained by connecting *modules* and modules consists of individual *cells*.

18-21C A house should be designed to receive (a) maximum solar heat in winter (to reduce heating energy consumption) in winter-dominated climates and (b) minimum solar heat gain in summer (to reduce cooling energy consumption) in summer-dominated climates.

18-22C Dark painted thick masonry walls called *trombe walls* are commonly used on south sides of passive solar homes to absorb solar energy, store it during the day, and release it to the house during the night. The use of trombe wall reduces the heating energy consumption of the building in winter.

12-23C (a) The spectral distribution of solar radiation beyond the earth's atmosphere resembles the energy emitted by a black body at 5982°C, with about 39 percent in the visible region (0.4 to 0.7 μm), and the 52 percent in the near infrared region (0.7 to 3.5 μm). (b) At a solar altitude of 41.8°, the total energy of direct solar radiation incident at sea level on a clear day consists of about 3 percent ultraviolet, 38 percent visible, and 59 percent infrared radiation.

12-24C A device that blocks solar radiation and thus reduces the solar heat gain is called a shading device. External shading devices are more effective in reducing the solar heat gain since they intercept sun's rays before they reach the glazing. The solar heat gain through a window can be reduced by as much as 80 percent by exterior shading. *Light colored* shading devices maximize the back reflection and thus minimize the solar gain. *Dark colored* shades, on the other hand, minimize the back reflection and thus maximize the solar heat gain.

12-25C The **solar heat gain coefficient (SHGC)** is defined as the fraction of incident solar radiation that enters through the glazing. The solar heat gain of a glazing relative to the solar heat gain of a reference glazing, typically that of a standard 3 mm (1/8 in) thick double-strength clear window glass sheet whose SHGC is 0.87, is called the **shading coefficient**. They are related to each other by

$$SC = \frac{\text{Solar heat gain of product}}{\text{Solar heat gain of reference glazing}} = \frac{SHGC}{SHGC_{ref}} = \frac{SHGC}{0.87} = 1.15 \times SHGC$$

For single pane clear glass window, SHGC = 0.87 and SC = 1.0.

12-26C The SC (shading coefficient) of a device represents the solar heat gain relative to the solar heat gain of a reference glazing, typically that of a standard 3 mm (1/8 in) thick double-strength clear window glass sheet whose SHGC is 0.87. The shading coefficient of a 3-mm thick *clear glass* is SC = 1.0 whereas SC = 0.88 for 3-mm thick *heat absorbing glass*.

12-27C A window that transmits visible part of the spectrum while absorbing the infrared portion is ideally suited for minimizing the air-conditioning load since such windows provide maximum daylighting and minimum solar heat gain. The ordinary window glass approximates this behavior remarkably well.

12-28C A low-e coating on the inner surface of a window glass reduces both the (a) heat loss in winter and (b) heat gain in summer. This is because the radiation heat transfer to or from the window is proportional to the emissivity of the inner surface of the window. In winter, the window is colder and thus radiation heat loss from the room to the window is low. In summer, the window is hotter and the radiation transfer from the window to the room is low.

18-29 The transmissivity of the glazing and the absorptivity of the absorber plate for a flat-plate solar collector are given. The maximum efficiency of the collector is to be determined.

Properties The transmissivity of glazing and the absorptivity of absorber plate are given in the problem statement.

Analysis The efficiency of a solar collector is defined as

$$\eta_c = \frac{\dot{Q}_{\text{useful}}}{\dot{Q}_{\text{incident}}} = \frac{\tau\alpha AG - UA(T_c - T_a)}{AG} = \tau\alpha - U \frac{T_c - T_a}{G}$$

The collector efficiency is maximum when the collector temperature is equal to the air temperature $T_c = T_a$ and thus $T_c - T_a = 0$. Therefore,

$$\eta_{c,\text{max}} = \tau\alpha = (0.82)(0.94) = 0.771 = \mathbf{77.1\text{percent}}$$

That is, the maximum efficiency of this collector is 77.1 percent.

18-30 The characteristics of a flat-plate solar collector and the rate of radiation incident are given. The collector efficiency is to be determined.

Properties The transmissivity of glazing and the absorptivity of absorber plate are given in the problem statement.

Analysis The efficiency of this solar collector is determined from

$$\begin{aligned} \eta_c &= \tau\alpha - U \frac{T_c - T_a}{G} \\ &= (0.86)(0.95) - (3 \text{ W/m}^2 \cdot \text{°C}) \frac{(45 - 23) \text{°C}}{750 \text{ W/m}^2} \\ &= 0.729 = \mathbf{72.9\text{percent}} \end{aligned}$$

That is, the efficiency of this collector is 72.9 percent.

18-31E The characteristics of a flat-plate solar collector and the rate of solar radiation incident are given. The collector efficiency is to be determined.

Properties The product of transmissivity of glazing and the absorptivity of absorber plate is given in the problem statement.

Analysis (a) The efficiency of single-glazing solar collector is determined from

$$\begin{aligned}\eta_c &= \tau\alpha - U \frac{T_c - T_a}{G} \\ &= (0.85) - (0.5 \text{ Btu/h} \cdot \text{ft}^2 \cdot ^\circ\text{F}) \frac{(120 - 67)^\circ\text{F}}{260 \text{ Btu/h} \cdot \text{ft}^2} \\ &= 0.748 = \mathbf{74.8\text{percent}}\end{aligned}$$

(b) The efficiency of double-glazing solar collector is determined similarly as

$$\begin{aligned}\eta_c &= \tau\alpha - U \frac{T_c - T_a}{G} \\ &= (0.80) - (0.3 \text{ Btu/h} \cdot \text{ft}^2 \cdot ^\circ\text{F}) \frac{(120 - 67)^\circ\text{F}}{260 \text{ Btu/h} \cdot \text{ft}^2} \\ &= 0.739 = \mathbf{73.9\text{percent}}\end{aligned}$$

The efficiency of single-glazing collector is slightly greater than that of double-glazing collector.

18-32 A flat-plate solar collector is used to produce hot water. The characteristics of a flat-plate solar collector and the rate of radiation incident are given. The temperature of hot water provided by the collector is to be determined.

Properties The product of transmissivity of glazing and the absorptivity of absorber plate is given in the problem statement. The density of water is 1000 kg/m^3 and its specific heat is $4.18 \text{ kJ/kg} \cdot ^\circ\text{C}$.

Analysis The total rate of solar radiation incident on the collector is

$$\dot{Q}_{\text{incident}} = AG = (33 \text{ m}^2)(880 \text{ W/m}^2) = 29,040 \text{ W}$$

The mass flow rate of water is

$$\dot{m} = \rho \dot{V} = (1 \text{ L/kg})(6.3/60 \text{ L/s}) = 0.105 \text{ kg/s}$$

The rate of useful heat transferred to the water is determined from the definition of collector efficiency to be

$$\eta_c = \frac{\dot{Q}_{\text{useful}}}{\dot{Q}_{\text{incident}}} \longrightarrow \dot{Q}_{\text{useful}} = \eta_c \dot{Q}_{\text{incident}} = (0.70)(29,040 \text{ W}) = 20,328 \text{ W}$$

Then the temperature of hot water provided by the collector is determined from

$$\begin{aligned}\dot{Q}_{\text{useful}} &= \dot{m}c_p(T_{w,\text{out}} - T_{w,\text{in}}) \\ 20,328 \text{ W} &= (0.105 \text{ kg/s})(4.28 \text{ kJ/kg} \cdot ^\circ\text{C})(T_{w,\text{out}} - 18)^\circ\text{C} \\ T_{w,\text{out}} &= \mathbf{64.3^\circ\text{C}}\end{aligned}$$

That is, this collector is supplying water at 64.3°C .

18-33E A flat-plate solar collector is considered. The collector efficiency for a given water inlet temperature and the water temperature for a collector efficiency of zero are to be determined.

Properties The transmissivity of glazing and the absorptivity of absorber plate are given in the problem statement.

Analysis (a) The efficiency of single-glazing solar collector is determined from

$$\begin{aligned}\eta_c &= F_R K_{\tau\alpha} \tau\alpha - F_R U \frac{T_{w,in} - T_a}{G} \\ &= (0.92)(1)(0.88)(0.97) - (0.92)(1.3 \text{ Btu/h} \cdot \text{ft}^2 \cdot ^\circ\text{F}) \frac{(115 - 60)^\circ\text{F}}{210 \text{ Btu/h} \cdot \text{ft}^2} \\ &= 0.472 = \mathbf{47.2\text{percent}}\end{aligned}$$

(b) Setting the collector efficiency zero in the efficiency relation gives

$$\begin{aligned}F_R K_{\tau\alpha} \tau\alpha - F_R U \frac{T_{w,in} - T_a}{G} &= 0 \\ F_R K_{\tau\alpha} \tau\alpha &= F_R U \frac{T_{w,in} - T_a}{G} \\ (0.92)(1)(0.88)(0.97) &= (0.92)(1.3 \text{ Btu/h} \cdot \text{ft}^2 \cdot ^\circ\text{F}) \frac{(T_{w,in} - 60)^\circ\text{F}}{210 \text{ Btu/h} \cdot \text{ft}^2} = 0 \\ T_{w,in} &= \mathbf{198^\circ\text{F}}\end{aligned}$$

18-34 The characteristics of a concentrating solar collector are given. The collector efficiency is to be determined.

Analysis The efficiency of this solar collector is determined from

$$\begin{aligned}\eta_c &= \eta_{ar} - U \frac{T_c - T_a}{\text{CR} \times G} = 0.93 - (4 \text{ W/m}^2 \cdot ^\circ\text{C}) \frac{(130 - 20)^\circ\text{C}}{(15)(520 \text{ W/m}^2)} \\ &= 0.874 = \mathbf{87.4\text{percent}}\end{aligned}$$

That is, the efficiency of this collector is 87.4 percent.

18-35 A solar power plant utilizing parabolic trough collectors is considered. The power generated is to be determined.

Analysis The efficiency of a solar power plant is defined as the power produced divided by the total solar irradiation. That is,

$$\eta_{\text{th,solar}} = \frac{\dot{W}_{\text{out}}}{\dot{Q}_{\text{incident}}} = \frac{\dot{W}_{\text{out}}}{A_c G}$$

Solving for the power output,

$$\dot{W}_{\text{out}} = \eta_{\text{th,solar}} A_c G = (0.08)(2500 \text{ m}^2)(0.700 \text{ kW/m}^2) = \mathbf{140 \text{ kW}}$$

18-36 A solar pond power plant with specified temperatures and thermal efficiency is considered. The second-law efficiency of the power plant power is to be determined.

Analysis The maximum thermal efficiency of this power plant is equal to Carnot efficiency, and is determined from

$$\eta_{\text{th,max}} = 1 - \frac{T_L}{T_H} = 1 - \frac{(30 + 273) \text{ K}}{(75 + 273) \text{ K}} = 0.1293$$

The second-law efficiency is the ratio of actual thermal efficiency to the maximum thermal efficiency:

$$\eta_{\text{II}} = \frac{\eta_{\text{th}}}{\eta_{\text{th,max}}} = \frac{0.036}{0.1293} = 0.278 = \mathbf{27.8\text{percent}}$$

18-37 A solar-power-tower plant is considered. The power output and thermal efficiency of the plant, the annual electricity production, and the cost of the plant are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) Using the turbine isentropic efficiency, the steam properties at the inlet and exit of the turbine are determined as follows: (Tables A-4E, A-5E, and A-6E),

$$\begin{aligned} P_1 = 160 \text{ psia} & \left. \begin{array}{l} h_1 = 1325.2 \text{ Btu/lbm} \\ T_1 = 600^\circ\text{F} \end{array} \right\} s_1 = 1.7037 \text{ Btu/lbm} \cdot \text{R} \\ P_2 = 2 \text{ psia} & \left. \begin{array}{l} h_{2s} = 989.43 \text{ Btu/lbm} \\ s_2 = s_1 \end{array} \right\} \\ \eta_T = \frac{h_1 - h_2}{h_1 - h_{2s}} & \longrightarrow h_2 = h_1 - \eta_T (h_1 - h_{2s}) \\ & = 1325.2 - (0.88)(1325.2 - 989.43) = 1029.7 \text{ Btu/lbm} \end{aligned}$$

Then the power output is

$$\begin{aligned} \dot{W}_{\text{out}} &= \dot{m}(h_1 - h_2) = (15 \times 3600 \text{ lbm/h})(1325.2 - 1029.7) \text{ Btu/lbm} = 1.596 \times 10^7 \text{ Btu/h} \\ &= (1.596 \times 10^7 \text{ Btu/h}) \left(\frac{1 \text{ kW}}{3412.14 \text{ Btu/h}} \right) = \mathbf{4677 \text{ kW}} \end{aligned}$$

The thermal efficiency of this power plant is equal to power output divided by the total solar incident on the heliostats:

$$\eta_{\text{th}} = \frac{\dot{W}_{\text{out}}}{AG} = \frac{1.596 \times 10^7 \text{ Btu/h}}{(400,000 \text{ ft}^2)(250 \text{ Btu/h} \cdot \text{ft}^2)} = 0.1596 = \mathbf{16.0\%}$$

(b) The solar data for Houston, Texas is given in Table 18-4. The daily average solar irradiation for an entire year on a horizontal surface is given to be $15.90 \text{ MJ/m}^2 \cdot \text{day}$. Multiplying this value with 365 days of the year gives an estimate of total solar irradiation on the heliostat surfaces. Using the definition of the thermal efficiency,

$$\begin{aligned} W_{\text{out}} &= \eta_{\text{th,avg}} AG \\ &= (0.12)(400,000 \text{ ft}^2)(15,900 \text{ kJ/m}^2 \cdot \text{day})(365 \text{ days}) \left(\frac{1 \text{ kWh}}{3600 \text{ kJ}} \right) \left(\frac{1 \text{ m}^2}{10.764 \text{ ft}^2} \right) \\ &= 7.189 \times 10^6 \text{ kWh} \end{aligned}$$

This is total power output from the turbine. The electrical energy output from the generator is

$$W_{\text{elect}} = \eta_{\text{gen}} W_{\text{out}} = (0.98)(7.189 \times 10^6 \text{ kWh}) = \mathbf{7.045 \times 10^6 \text{ kWh}}$$

(c) The total cost of this power plant is

$$\text{Plant cost} = \text{Unit cost} \times \dot{W}_{\text{out}} = (\$17,000/\text{kW})(4677 \text{ kW}) = \$7.949 \times 10^7$$

The annual revenue from selling the electricity produced is

$$\begin{aligned} \text{Annual revenue} &= \dot{W}_{\text{out}} \times \text{Unit price} \times \text{Operating hours} \\ &= (4677 \text{ kW})(\$0.11/\text{kW})(4500 \text{ h}) \\ &= \$2.315 \times 10^6/\text{year} \end{aligned}$$

The simple payback period is then

$$\text{Payback period} = \frac{\text{Plant cost}}{\text{Annual revenue}} = \frac{\$7.949 \times 10^7}{\$2.315 \times 10^6/\text{year}} = \mathbf{34.3 \text{ years}}$$

That is, this plant pays for itself in 34 years, which is not unexpected for solar power plants.

18-38 A solar cell with a specified value of open circuit voltage is considered. The current output density, the load voltage for maximum power output, and the maximum power output of the cell for a unit cell area are to be determined.

Analysis (a) The current output density is determined from Eq. 18-18 to be

$$V_{oc} = \frac{kT}{e_o} \ln\left(\frac{J_s}{J_o} + 1\right)$$

$$0.55 \text{ V} = \frac{(1.381 \times 10^{-23} \text{ J/K})(298 \text{ K})}{1.6 \times 10^{-19} \text{ J/V}} \ln\left(\frac{J_s}{1.9 \times 10^{-9} \text{ A/m}^2} + 1\right)$$

$$J_s = \mathbf{3.676 \text{ A/m}^2}$$

(b) The load voltage at which the power output is maximum is determined from Eq. 18-22 to be

$$\exp\left(\frac{e_o V_{\max}}{kT}\right) = \frac{1 + J_s / J_o}{1 + \frac{e_o V_{\max}}{kT}}$$

$$\exp\left(\frac{(1.6 \times 10^{-19} \text{ J/V})V_{\max}}{(1.381 \times 10^{-23} \text{ J/K})(298 \text{ K})}\right) = \frac{1 + (3.676 \text{ A/m}^2 / 1.9 \times 10^{-9} \text{ A/m}^2)}{1 + \frac{(1.6 \times 10^{-19} \text{ J/V})V_{\max}}{(1.381 \times 10^{-23} \text{ J/K})(298 \text{ K})}}$$

$$V_{\max} = \mathbf{0.4737 \text{ V}}$$

(c) The maximum power output of the cell for a unit cell area is determined from

$$\dot{W}_{\max} = \frac{V_{\max} (J_s + J_o)}{1 + \frac{kT}{e_o V_{\max}}} = \frac{(0.4737 \text{ V})(3.676 \text{ A/m}^2)(1.9 \times 10^{-9} \text{ A/m}^2)}{1 + \frac{(1.381 \times 10^{-23} \text{ J/K})(298 \text{ K})}{(1.6 \times 10^{-19} \text{ J/V})(0.4737 \text{ V})}} = \mathbf{1.652 \text{ W/m}^2}$$

18-39 A solar cell with a specified value of open circuit voltage is considered. The power output and the efficiency of the cell are to be determined.

Analysis The current output density is determined from Eq. 18-18 to be

$$V_{oc} = \frac{kT}{e_o} \ln \left(\frac{J_s}{J_o} + 1 \right)$$

$$0.60 \text{ V} = \frac{(1.381 \times 10^{-23} \text{ J/K})(300 \text{ K})}{1.6 \times 10^{-19} \text{ J/V}} \ln \left(\frac{J_s}{3.9 \times 10^{-9} \text{ A/m}^2} + 1 \right)$$

$$J_s = 45.12 \text{ A/m}^2$$

The power output is

$$\dot{W} = VAJ_s - VAJ_o \left[\exp \left(\frac{e_o V}{kT} \right) - 1 \right]$$

$$= (0.52 \text{ V})(28 \text{ m}^2)(45.12 \text{ A/m}^2) - (0.52 \text{ V})(28 \text{ m}^2)(3.9 \times 10^{-9} \text{ A/m}^2) \left[\exp \left(\frac{(1.6 \times 10^{-19} \text{ J/V})(0.52 \text{ V})}{(1.381 \times 10^{-23} \text{ J/K})(300 \text{ K})} \right) - 1 \right]$$

$$= \mathbf{627 \text{ W}}$$

The efficiency of the cell is

$$\eta_{th} = \frac{\dot{W}}{AG} = \frac{627 \text{ W}}{(28 \text{ m}^2)(485 \text{ W/m}^2)} = 0.0462 = \mathbf{4.62 \text{ percent}}$$

18-40E A solar cell with a specified value of open circuit voltage is considered. The load voltage for maximum power output, the efficiency of the cell, and the cell area for a given power output are to be determined.

Analysis (a) The current output density is determined from Eq. 18-18 to be

$$V_{oc} = \frac{kT}{e_o} \ln \left(\frac{J_s}{J_o} + 1 \right)$$

$$0.60 \text{ V} = \frac{(1.381 \times 10^{-23} \text{ J/K})[(75 - 32)/1.8 + 273.15] \text{ K}}{1.6 \times 10^{-19} \text{ J/V}} \ln \left(\frac{J_s}{4.11 \times 10^{-10} \text{ A/ft}^2 \left(\frac{10.764 \text{ ft}^2}{1 \text{ m}^2} \right)} + 1 \right)$$

$$J_s = 64.48 \text{ A/m}^2$$

The load voltage at which the power output is maximum is determined from Eq. 18-22 to be

$$\exp \left(\frac{e_o V_{\max}}{kT} \right) = \frac{1 + J_s / J_o}{1 + \frac{e_o V_{\max}}{kT}}$$

$$\exp \left(\frac{(1.6 \times 10^{-19} \text{ J/V}) V_{\max}}{(1.381 \times 10^{-23} \text{ J/K})[(75 - 32)/1.8 + 273.15] \text{ K}} \right) = \frac{1 + (64.48 \text{ A/m}^2) / \left[4.11 \times 10^{-10} \text{ A/ft}^2 \left(\frac{10.764 \text{ ft}^2}{1 \text{ m}^2} \right) \right]}{1 + \frac{(1.6 \times 10^{-19} \text{ J/V}) V_{\max}}{(1.381 \times 10^{-23} \text{ J/K})[(75 - 32)/1.8 + 273.15] \text{ K}}}$$

$$V_{\max} = \mathbf{0.5215 \text{ V}}$$

(b) The load current density J_L is determined from

$$J_L = J_s - J_j = J_s - J_o \left[\exp \left(\frac{e_o V}{kT} \right) - 1 \right]$$

$$= (64.48 \text{ A/m}^2) - \left[4.11 \times 10^{-10} \text{ A/ft}^2 \left(\frac{10.764 \text{ ft}^2}{1 \text{ m}^2} \right) \right] \exp \left[\left(\frac{(1.6 \times 10^{-19} \text{ J/V})(0.56 \text{ V})}{(1.381 \times 10^{-23} \text{ J/K})[(75 - 32)/1.8 + 273.15] \text{ K}} \right) - 1 \right]$$

$$= 50.93 \text{ A/m}^2$$

The power output is

$$\dot{W} = J_L V = (50.93 \text{ A/m}^2)(0.56 \text{ V}) = 28.52 \text{ W/m}^2$$

The efficiency of the cell is

$$\eta_{\text{th}} = \frac{\dot{W}}{G} = \frac{28.52 \text{ W/m}^2}{(220 \text{ Btu/h} \cdot \text{ft}^2) \left(\frac{1 \text{ W/m}^2}{0.3171 \text{ Btu/h} \cdot \text{ft}^2} \right)} = 0.0411 = \mathbf{4.11 \text{ percent}}$$

(c) Finally, the cell area for a power output of 500 W is

$$A = \frac{\dot{W}_{\text{total}}}{\dot{W}} = \frac{500 \text{ W}}{28.52 \text{ W/m}^2} \left(\frac{10.764 \text{ ft}^2}{1 \text{ m}^2} \right) = \mathbf{188.7 \text{ ft}^2}$$

18-41E A solar cell with a specified value of open circuit voltage is considered. The maximum conversion efficiency of the solar cell is to be determined.

Analysis The current output density is determined from Eq. 18-18 to be

$$V_{oc} = \frac{kT}{e_o} \ln \left(\frac{J_s}{J_o} + 1 \right)$$

$$0.60 \text{ V} = \frac{(1.381 \times 10^{-23} \text{ J/K})[(75 - 32)/1.8 + 273.15] \text{ K}}{1.6 \times 10^{-19} \text{ J/V}} \ln \left(\frac{J_s}{4.11 \times 10^{-10} \text{ A/ft}^2 \left(\frac{10.764 \text{ ft}^2}{1 \text{ m}^2} \right)} + 1 \right)$$

$$J_s = 64.48 \text{ A/m}^2$$

The load voltage at which the power output is maximum is determined from Eq. 18-22 to be

$$\exp \left(\frac{e_o V_{\max}}{kT} \right) = \frac{1 + J_s / J_o}{1 + \frac{e_o V_{\max}}{kT}}$$

$$\exp \left(\frac{(1.6 \times 10^{-19} \text{ J/V}) V_{\max}}{(1.381 \times 10^{-23} \text{ J/K})[(75 - 32)/1.8 + 273.15] \text{ K}} \right) = \frac{1 + (64.48 \text{ A/m}^2) / \left[4.11 \times 10^{-10} \text{ A/ft}^2 \left(\frac{10.764 \text{ ft}^2}{1 \text{ m}^2} \right) \right]}{1 + \frac{(1.6 \times 10^{-19} \text{ J/V}) V_{\max}}{(1.381 \times 10^{-23} \text{ J/K})[(75 - 32)/1.8 + 273.15] \text{ K}}}$$

$$V_{\max} = \mathbf{0.5215 \text{ V}}$$

The maximum conversion efficiency of this solar cell is determined from

$$\eta_{\text{cell,max}} = \frac{V_{\max} (J_s + J_o)}{G \left(1 + \frac{kT}{e_o V_{\max}} \right)}$$

$$= \frac{(0.5215 \text{ V})(64.48 \text{ A/m}^2) + \left[4.11 \times 10^{-10} \text{ A/ft}^2 \left(\frac{10.764 \text{ ft}^2}{1 \text{ m}^2} \right) \right]}{\left[(220 \text{ Btu/h} \cdot \text{ft}^2) \left(\frac{1 \text{ W/m}^2}{0.3171 \text{ Btu/h} \cdot \text{ft}^2} \right) \right] \left(1 + \frac{(1.381 \times 10^{-23} \text{ J/K})[(75 - 32)/1.8 + 273.15] \text{ K}}{(1.6 \times 10^{-19} \text{ J/V})(0.5215 \text{ V})} \right)}$$

$$= 0.04619 = \mathbf{4.62 \text{ percent}}$$

18-42 The thermal efficiency of a solar car using solar cells is to be determined.

Analysis The thermal efficiency of the solar car is determined from

$$\eta_{\text{th}} = \frac{\dot{W}}{AG} = \frac{540 \text{ W}}{(8 \text{ m}^2)(860 \text{ W/m}^2)} = 0.0785 = \mathbf{7.85 \text{ percent}}$$

18-43 A building located near 40° N latitude has equal window areas on all four sides. The side of the building with the highest solar heat gain in summer is to be determined.

Assumptions The shading coefficients of windows on all sides of the building are identical.

Analysis The reflective films should be installed on the side that receives the most incident solar radiation in summer since the window areas and the shading coefficients on all four sides are identical. The incident solar radiation at different windows in July are given to be (Table 18-3)

Month	Time	The daily total solar radiation incident on the surface, Wh/m ²			
		North	East	South	West
July	Daily total	1621	4313	2552	4313

Therefore, the reflective film should be installed on the **East** or **West** windows (instead of the South windows) in order to minimize the solar heat gain and thus the cooling load of the building.

18-44 The net annual cost savings due to installing reflective coating on the West windows of a building and the simple payback period are to be determined.

Assumptions 1 The calculations given below are for an average year. 2 The unit costs of electricity and natural gas remain constant.

Analysis Using the daily averages for each month and noting the number of days of each month, the total solar heat flux incident on the glazing during summer and winter months are determined to be

$$Q_{\text{solar, summer}} = 4.24 \times 30 + 4.16 \times 31 + 3.93 \times 31 + 3.48 \times 30 \\ = 482 \text{ kWh/year}$$

$$Q_{\text{solar, winter}} = 2.94 \times 31 + 2.33 \times 30 + 2.07 \times 31 + 2.35 \times 31 + 3.03 \times 28 + 3.62 \times 31 + 4.00 \times 30 \\ = 615 \text{ kWh/year}$$

Then the decrease in the annual cooling load and the increase in the annual heating load due to reflective film become

$$\text{Cooling load decrease} = Q_{\text{solar, summer}} A_{\text{glazing}} (\text{SHGC}_{\text{without film}} - \text{SHGC}_{\text{with film}}) \\ = (482 \text{ kWh/year})(60 \text{ m}^2)(0.766 - 0.35) \\ = 12,031 \text{ kWh/year}$$

$$\text{Heating load increase} = Q_{\text{solar, winter}} A_{\text{glazing}} (\text{SHGC}_{\text{without film}} - \text{SHGC}_{\text{with film}}) \\ = (615 \text{ kWh/year})(60 \text{ m}^2)(0.766 - 0.35) \\ = 15,350 \text{ kWh/year} = 523.7 \text{ therms/year}$$

since 1 therm = 29.31 kWh. The corresponding decrease in cooling costs and increase in heating costs are

$$\text{Decrease in cooling costs} = (\text{Cooling load decrease})(\text{Unit cost of electricity})/\text{COP} \\ = (12,031 \text{ kWh/year})(\$0.15/\text{kWh})/3.2 = \$564/\text{year}$$

$$\text{Increase in heating costs} = (\text{Heating load increase})(\text{Unit cost of fuel})/\text{Efficiency} \\ = (523.7 \text{ therms/year})(\$0.90/\text{therm})/0.90 = \$524/\text{year}$$

Then the net annual cost savings due to reflective films become

$$\text{Cost Savings} = \text{Decrease in cooling costs} - \text{Increase in heating costs} = \$564 - 524 = \mathbf{\$40/\text{year}}$$

The implementation cost of installing films is

$$\text{Implementation Cost} = (\$15/\text{m}^2)(60 \text{ m}^2) = \$900$$

This gives a simple payback period of

$$\text{Simple payback period} = \frac{\text{Implementation cost}}{\text{Annual cost savings}} = \frac{\$900}{\$40/\text{year}} = \mathbf{22.5 \text{ years}}$$

Discussion The reflective films will pay for themselves in this case in about 23 years, which is unacceptable to most manufacturers since they are not usually interested in any energy conservation measure which does not pay for itself within 3 years.

18-45 A house located at 40°N latitude has ordinary double pane windows. The total solar heat gain of the house at 9:00, 12:00, and 15:00 solar time in July and the total amount of solar heat gain per day for an average day in January are to be determined.

Assumptions The calculations are performed for an average day in a given month.

Properties The shading coefficient of a double pane window with 6-mm thick glasses is $SC = 0.82$ (Table 18-6). The incident radiation at different windows at different times are given as (Table 8-3)

Month	Time	Solar radiation incident on the surface, W/m^2			
		North	East	South	West
July	9:00	117	701	190	114
July	12:00	138	149	395	149
July	15:00	117	114	190	701
January	Daily total	446	1863	5897	1863

Analysis The solar heat gain coefficient (SHGC) of the windows is determined from Eq.12-57 to be

$$SHGC = 0.87 \times SC = 0.87 \times 0.82 = 0.7134$$

The rate of solar heat gain is determined from

$$\begin{aligned}\dot{Q}_{\text{solar gain}} &= SHGC \times A_{\text{glazing}} \times \dot{q}_{\text{solar, incident}} \\ &= 0.7134 \times A_{\text{glazing}} \times \dot{q}_{\text{solar, incident}}\end{aligned}$$

Then the rates of heat gain at the 4 walls at 3 different times in July become

North wall:

$$\begin{aligned}\dot{Q}_{\text{solar gain, 9:00}} &= 0.7134 \times (4 \text{ m}^2) \times (117 \text{ W/m}^2) = \mathbf{334 \text{ W}} \\ \dot{Q}_{\text{solar gain, 12:00}} &= 0.7134 \times (4 \text{ m}^2) \times (138 \text{ W/m}^2) = \mathbf{394 \text{ W}} \\ \dot{Q}_{\text{solar gain, 15:00}} &= 0.7134 \times (4 \text{ m}^2) \times (117 \text{ W/m}^2) = \mathbf{334 \text{ W}}\end{aligned}$$

East wall:

$$\begin{aligned}\dot{Q}_{\text{solar gain, 9:00}} &= 0.7134 \times (6 \text{ m}^2) \times (701 \text{ W/m}^2) = \mathbf{3001 \text{ W}} \\ \dot{Q}_{\text{solar gain, 12:00}} &= 0.7134 \times (6 \text{ m}^2) \times (149 \text{ W/m}^2) = \mathbf{638 \text{ W}} \\ \dot{Q}_{\text{solar gain, 15:00}} &= 0.7134 \times (6 \text{ m}^2) \times (114 \text{ W/m}^2) = \mathbf{488 \text{ W}}\end{aligned}$$

South wall:

$$\begin{aligned}\dot{Q}_{\text{solar gain, 9:00}} &= 0.7134 \times (8 \text{ m}^2) \times (190 \text{ W/m}^2) = \mathbf{1084 \text{ W}} \\ \dot{Q}_{\text{solar gain, 12:00}} &= 0.7134 \times (8 \text{ m}^2) \times (395 \text{ W/m}^2) = \mathbf{2254 \text{ W}} \\ \dot{Q}_{\text{solar gain, 15:00}} &= 0.7134 \times (8 \text{ m}^2) \times (190 \text{ W/m}^2) = \mathbf{1084 \text{ W}}\end{aligned}$$

West wall:

$$\begin{aligned}\dot{Q}_{\text{solar gain, 9:00}} &= 0.7134 \times (6 \text{ m}^2) \times (114 \text{ W/m}^2) = \mathbf{488 \text{ W}} \\ \dot{Q}_{\text{solar gain, 12:00}} &= 0.7134 \times (6 \text{ m}^2) \times (149 \text{ W/m}^2) = \mathbf{638 \text{ W}} \\ \dot{Q}_{\text{solar gain, 15:00}} &= 0.7134 \times (6 \text{ m}^2) \times (701 \text{ W/m}^2) = \mathbf{3001 \text{ W}}\end{aligned}$$

Similarly, the solar heat gain of the house through all of the windows in January is determined to be

January:

$$\dot{Q}_{\text{solar gain, North}} = 0.7134 \times (4 \text{ m}^2) \times (446 \text{ Wh/m}^2 \cdot \text{day}) = 1273 \text{ Wh/day}$$

$$\dot{Q}_{\text{solar gain, East}} = 0.7134 \times (6 \text{ m}^2) \times (1863 \text{ Wh/m}^2 \cdot \text{day}) = 7974 \text{ Wh/day}$$

$$\dot{Q}_{\text{solar gain, South}} = 0.7134 \times (8 \text{ m}^2) \times (5897 \text{ Wh/m}^2 \cdot \text{day}) = 33,655 \text{ Wh/day}$$

$$\dot{Q}_{\text{solar gain, West}} = 0.7134 \times (6 \text{ m}^2) \times (1863 \text{ Wh/m}^2 \cdot \text{day}) = 7974 \text{ Wh/day}$$

Therefore, for an average day in January,

$$\dot{Q}_{\text{solar gain per day}} = 1273 + 7974 + 33,655 + 7974 = 58,876 \text{ Wh/day} \cong \mathbf{58.9 \text{ kWh/day}}$$

18-46 A house located at 40° N latitude has gray-tinted double pane windows. The total solar heat gain of the house at 9:00, 12:00, and 15:00 solar time in July and the total amount of solar heat gain per day for an average day in January are to be determined.

Assumptions The calculations are performed for an average day in a given month.

Properties The shading coefficient of a gray-tinted double pane window with 6-mm thick glasses is $SC = 0.58$ (Table 18-6). The incident radiation at different windows at different times are given as (Table 18-3)

Month	Time	Solar radiation incident on the surface, W/m ²			
		North	East	South	West
July	9:00	117	701	190	114
July	12:00	138	149	395	149
July	15:00	117	114	190	701
January	Daily total	446	1863	5897	1863

Analysis The solar heat gain coefficient (SHGC) of the windows is determined from Eq.11-57 to be

$$SHGC = 0.87 \times SC = 0.87 \times 0.58 = 0.5046$$

The rate of solar heat gain is determined from

$$\dot{Q}_{\text{solar gain}} = SHGC \times A_{\text{glazing}} \times \dot{q}_{\text{solar, incident}} = 0.5046 \times A_{\text{glazing}} \times \dot{q}_{\text{solar, incident}}$$

Then the rates of heat gain at the 4 walls at 3 different times in July become

North wall:

$$\dot{Q}_{\text{solar gain, 9:00}} = 0.5046 \times (4 \text{ m}^2) \times (117 \text{ W/m}^2) = \mathbf{236 \text{ W}}$$

$$\dot{Q}_{\text{solar gain, 12:00}} = 0.5046 \times (4 \text{ m}^2) \times (138 \text{ W/m}^2) = \mathbf{279 \text{ W}}$$

$$\dot{Q}_{\text{solar gain, 15:00}} = 0.5046 \times (4 \text{ m}^2) \times (117 \text{ W/m}^2) = \mathbf{236 \text{ W}}$$

East wall:

$$\dot{Q}_{\text{solar gain, 9:00}} = 0.5046 \times (6 \text{ m}^2) \times (701 \text{ W/m}^2) = \mathbf{2122 \text{ W}}$$

$$\dot{Q}_{\text{solar gain, 12:00}} = 0.5046 \times (6 \text{ m}^2) \times (149 \text{ W/m}^2) = \mathbf{451 \text{ W}}$$

$$\dot{Q}_{\text{solar gain, 15:00}} = 0.5046 \times (6 \text{ m}^2) \times (114 \text{ W/m}^2) = \mathbf{345 \text{ W}}$$

South wall:

$$\dot{Q}_{\text{solar gain, 9:00}} = 0.5046 \times (8 \text{ m}^2) \times (190 \text{ W/m}^2) = \mathbf{767 \text{ W}}$$

$$\dot{Q}_{\text{solar gain, 12:00}} = 0.5046 \times (8 \text{ m}^2) \times (395 \text{ W/m}^2) = \mathbf{1595 \text{ W}}$$

$$\dot{Q}_{\text{solar gain, 15:00}} = 0.5046 \times (8 \text{ m}^2) \times (190 \text{ W/m}^2) = \mathbf{767 \text{ W}}$$

West wall:

$$\dot{Q}_{\text{solar gain, 9:00}} = 0.5046 \times (6 \text{ m}^2) \times (114 \text{ W/m}^2) = \mathbf{345 \text{ W}}$$

$$\dot{Q}_{\text{solar gain, 12:00}} = 0.5046 \times (6 \text{ m}^2) \times (149 \text{ W/m}^2) = \mathbf{451 \text{ W}}$$

$$\dot{Q}_{\text{solar gain, 15:00}} = 0.5046 \times (6 \text{ m}^2) \times (701 \text{ W/m}^2) = \mathbf{2122 \text{ W}}$$

Similarly, the solar heat gain of the house through all of the windows in January is determined to be

January:

$$\dot{Q}_{\text{solar gain, North}} = 0.5046 \times (4 \text{ m}^2) \times (446 \text{ Wh/m}^2 \cdot \text{day}) = 900 \text{ Wh/day}$$

$$\dot{Q}_{\text{solar gain, East}} = 0.5046 \times (6 \text{ m}^2) \times (1863 \text{ Wh/m}^2 \cdot \text{day}) = 5640 \text{ Wh/day}$$

$$\dot{Q}_{\text{solar gain, South}} = 0.5046 \times (8 \text{ m}^2) \times (5897 \text{ Wh/m}^2 \cdot \text{day}) = 23,805 \text{ Wh/day}$$

$$\dot{Q}_{\text{solar gain, West}} = 0.5046 \times (6 \text{ m}^2) \times (1863 \text{ Wh/m}^2 \cdot \text{day}) = 5640 \text{ Wh/day}$$

Therefore, for an average day in January,

$$\dot{Q}_{\text{solar gain per day}} = 900 + 5640 + 23,805 + 5640 = 35,985 \text{ Wh/day} = \mathbf{35.895 \text{ kWh/day}}$$

18-47 A building at 40° N latitude has double pane heat absorbing type windows that are equipped with light colored venetian blinds. The total solar heat gains of the building through the south windows at solar noon in April for the cases of with and without the blinds are to be determined.

Assumptions The calculations are performed for an “average” day in April, and may vary from location to location.

Properties The shading coefficient of a double pane heat absorbing type windows is $SC = 0.58$ (Table 18-6). It is given to be $SC = 0.30$ in the case of blinds. The solar radiation incident at a South-facing surface at 12:00 noon in April is 559 W/m^2 (Table 18-3).

Analysis The solar heat gain coefficient (SHGC) of the windows without the blinds is determined from

$$SHGC = 0.87 \times SC = 0.87 \times 0.58 = 0.5046$$

Then the rate of solar heat gain through the window becomes

$$\begin{aligned} \dot{Q}_{\text{solar gain, no blinds}} &= SHGC \times A_{\text{glazing}} \times \dot{q}_{\text{solar, incident}} \\ &= 0.5046(76 \text{ m}^2)(559 \text{ W/m}^2) \\ &= \mathbf{21,440 \text{ W}} \end{aligned}$$

In the case of windows equipped with venetian blinds, the SHGC and the rate of solar heat gain become

$$SHGC = 0.87 \times SC = 0.87 \times 0.30 = 0.261$$

Then the rate of solar heat gain through the window becomes

$$\begin{aligned} \dot{Q}_{\text{solar gain, no blinds}} &= SHGC \times A_{\text{glazing}} \times \dot{q}_{\text{solar, incident}} \\ &= 0.261(76 \text{ m}^2)(559 \text{ W/m}^2) \\ &= \mathbf{11,090 \text{ W}} \end{aligned}$$

Discussion Note that light colored venetian blinds significantly reduce the solar heat, and thus air-conditioning load in summers.

18-48 A house has double door type windows that are double pane with 6.4 mm of air space and aluminum frames and spacers. It is to be determined if the house is losing more or less heat than it is gaining from the sun through an east window in a typical day in January.

Assumptions 1 The calculations are performed for an “average” day in January. **2** Solar data at 40° latitude can also be used for a location at 39° latitude.

Properties The shading coefficient of a double pane window with 3-mm thick clear glass is $SC = 0.88$ (Table 18-6). The overall heat transfer coefficient for double door type windows that are double pane with 6.4 mm of air space and aluminum frames and spacers is $4.55 \text{ W/m}^2 \cdot ^\circ\text{C}$. The total solar radiation incident at an East-facing surface in January during a typical day is 1863 Wh/m^2 (Table 18-3).

Analysis The solar heat gain coefficient (SHGC) of the windows is determined from

$$SHGC = 0.87 \times SC = 0.87 \times 0.88 = 0.7656$$

Then the solar heat gain through the window per unit area becomes

$$\begin{aligned} Q_{\text{solar gain}} &= SHGC \times A_{\text{glazing}} \times q_{\text{solar, daily total}} \\ &= 0.7656(1 \text{ m}^2)(1863 \text{ Wh/m}^2) \\ &= \mathbf{1426 \text{ Wh} = 1.426 \text{ kWh}} \end{aligned}$$

The heat loss through a unit area of the window during a 24-h period is

$$\begin{aligned} Q_{\text{loss, window}} &= \dot{Q}_{\text{loss, window}} \Delta t = U_{\text{window}} A_{\text{window}} (T_i - T_{0, \text{ave}})(1 \text{ day}) \\ &= (4.55 \text{ W/m}^2 \cdot ^\circ\text{C})(1 \text{ m}^2)(22 - 10)^\circ\text{C}(24 \text{ h}) \\ &= \mathbf{1310 \text{ Wh} = 1.31 \text{ kWh}} \end{aligned}$$

Therefore, the house is losing **less** heat than it is gaining through the East windows during a typical day in January.

18-49 A house has double door type windows that are double pane with 6.4 mm of air space and aluminum frames and spacers. It is to be determined if the house is losing more or less heat than it is gaining from the sun through a South window in a typical day in January.

Assumptions 1 The calculations are performed for an “average” day in January. **2** Solar data at 40° latitude can also be used for a location at 39° latitude.

Properties The shading coefficient of a double pane window with 3-mm thick clear glass is $SC = 0.88$ (Table 18-6). The overall heat transfer coefficient for double door type windows that are double pane with 6.4 mm of air space and aluminum frames and spacers is $4.55 \text{ W/m}^2 \cdot ^\circ\text{C}$. The total solar radiation incident at a South-facing surface in January during a typical day is 5897 Wh/m^2 (Table 18-3).

Analysis The solar heat gain coefficient (SHGC) of the windows is determined from

$$SHGC = 0.87 \times SC = 0.87 \times 0.88 = 0.7656$$

Then the solar heat gain through the window per unit area becomes

$$\begin{aligned} Q_{\text{solar gain}} &= SHGC \times A_{\text{glazing}} \times q_{\text{solar, daily total}} \\ &= 0.7656(1 \text{ m}^2)(5897 \text{ Wh/m}^2) \\ &= \mathbf{4515 \text{ Wh} = 4.515 \text{ kWh}} \end{aligned}$$

The heat loss through a unit area of the window during a 24-h period is

$$\begin{aligned} Q_{\text{loss, window}} &= \dot{Q}_{\text{loss, window}} \Delta t = U_{\text{window}} A_{\text{window}} (T_i - T_{0, \text{ave}})(1 \text{ day}) \\ &= (4.55 \text{ W/m}^2 \cdot ^\circ\text{C})(1 \text{ m}^2)(22 - 10)^\circ\text{C}(24 \text{ h}) \\ &= \mathbf{1310 \text{ Wh} = 1.31 \text{ kWh}} \end{aligned}$$

Therefore, the house is **losing** much less heat than it is gaining through the South windows during a typical day in January.

18-50E A house has 1/8-in thick single pane windows with aluminum frames on a West wall. The rate of net heat gain (or loss) through the window at 3 PM during a typical day in January is to be determined.

Assumptions 1 The calculations are performed for an “average” day in January. 2 The frame area relative to glazing area is small so that the glazing area can be taken to be the same as the window area.

Properties The shading coefficient of a 1/8-in thick single pane window is $SC = 1.0$ (Table 18-6). The overall heat transfer coefficient for 1/8-in thick single pane windows with aluminum frames is $6.63 \text{ W/m}^2 \cdot ^\circ\text{C} = 1.17 \text{ Btu/h}\cdot\text{ft}^2 \cdot ^\circ\text{F}$. The total solar radiation incident at a West-facing surface at 3 PM in January during a typical day is $557 \text{ W/m}^2 = 177 \text{ Btu/h}\cdot\text{ft}^2$ (Table 18-3).

Analysis The solar heat gain coefficient (SHGC) of the windows is determined from

$$SHGC = 0.87 \times SC = 0.87 \times 1.0 = 0.87$$

The window area is: $A_{\text{window}} = (9 \text{ ft})(15 \text{ ft}) = 135 \text{ ft}^2$

Then the rate of solar heat gain through the window at 3 PM becomes

$$\begin{aligned} \dot{Q}_{\text{solar gain, 3 PM}} &= SHGC \times A_{\text{glazing}} \times \dot{q}_{\text{solar, 3 PM}} \\ &= 0.87(135 \text{ ft}^2)(177 \text{ Btu/h}\cdot\text{ft}^2) \\ &= 20,789 \text{ Btu/h} \end{aligned}$$

The rate of heat loss through the window at 3 PM is

$$\begin{aligned} \dot{Q}_{\text{loss, window}} &= U_{\text{window}} A_{\text{window}} (T_i - T_o) \\ &= (1.17 \text{ Btu/h}\cdot\text{ft}^2 \cdot ^\circ\text{F})(135 \text{ ft}^2)(78 - 20)^\circ\text{F} \\ &= 9161 \text{ Btu/h} \end{aligned}$$

The house will be gaining heat at 3 PM since the solar heat gain is larger than the heat loss. The rate of net heat gain through the window is

$$\dot{Q}_{\text{net}} = \dot{Q}_{\text{solar gain, 3 PM}} - \dot{Q}_{\text{loss, window}} = 20,789 - 9161 = \mathbf{11,630 \text{ Btu/h}}$$

Discussion The actual heat gain will be less because of the area occupied by the window frame.

Wind Energy

18-51C *Windmill* is used for *mechanical* power generation (grinding grain, pumping water, etc.) but *wind turbine* is used for electrical power generation, although technically both devices are turbines since they extract energy from the fluid.

18-52C Theoretically, electricity can be generated at all wind speeds but for economical power generation, the minimum wind speed should be about 6 m/s.

18-53C *Cut-in speed* is the minimum wind speed at which useful power can be generated. *Rated speed* is the wind speed that delivers the rated power, usually the maximum power. *Cut-out speed* is the maximum wind speed at which the wind turbine is designed to produce power. At wind speeds greater than the cut-out speed, the turbine blades are stopped by some type of braking mechanism to avoid damage and for safety issues.

18-54C The wind power potential is given by

$$\dot{W}_{\text{available}} = \frac{1}{2} \rho A V^3$$

where ρ is the density of air, A is the blade span area of the wind turbine, and V is the wind velocity. The power potential of a wind turbine is proportional to the density of air, and the density of air is inversely proportional to air temperature through the relation $\rho = \frac{P}{RT}$. Therefore, the location with cooler air has more wind power potential. Note that both locations are at the same pressure since they are at the same altitude.

18-55C The wind power potential is given by

$$\dot{W}_{\text{available}} = \frac{1}{2} \rho A V^3$$

where ρ is the density of air, A is the blade span area of the wind turbine, and V is the wind velocity. The power potential of a wind turbine is proportional to the density of air and the density of air is proportional to atmospheric pressure through the relation $\rho = \frac{P}{RT}$. Since atmospheric pressure is higher at a lower altitude, the location at higher altitude has more wind power potential.

18-56C As a general rule of thumb, a location is considered poor for construction of wind turbines if the average wind power density is less than about 100 W/m², good if it is around 400 W/m², and great if it is greater than about 700 W/m². Therefore, we recommend wind turbine installation in site B and site C only.

18-57C The overall wind turbine efficiency is defined as

$$\eta_{\text{wt,overall}} = \frac{\dot{W}_{\text{electric}}}{\dot{W}_{\text{available}}} = \frac{\dot{W}_{\text{electric}}}{\frac{1}{2} \rho A V^3}$$

where $\dot{W}_{\text{electric}}$ is electric power output, ρ is density of air, A is blade span area, and V is wind velocity. The overall wind turbine efficiency is related to wind turbine efficiency as

$$\eta_{\text{wt,overall}} = \eta_{\text{wt}} \eta_{\text{gearbox/generator}} = \frac{\dot{W}_{\text{shaft}}}{\dot{W}_{\text{available}}} \frac{\dot{W}_{\text{electric}}}{\dot{W}_{\text{shaft}}} = \frac{\dot{W}_{\text{electric}}}{\dot{W}_{\text{available}}}$$

where $\eta_{\text{gearbox/generator}}$ is the gearbox/generator efficiency.

18-58C The theoretical limit for wind turbine efficiency based on the second law of thermodynamics is 100 percent. This represents the conversion of entire kinetic energy of wind into work. This would be the case only when the velocity of air at the turbine exit is zero. This is not possible for practical reasons because air must be taken away at the turbine exit to maintain the mass flow through the turbine. Therefore, there is a limit for wind turbine efficiency which is less than 100 percent, and this is called the Betz limit. The Betz limit is calculated to be 0.5926.

18-59C Turbine A: The given efficiency (41 percent) is *possible* and *realistic*. Turbine B: The given efficiency (59 percent) is *possible* because it is less than Betz limit but is *not probable*. Turbine C: The given efficiency (67 percent) is *not possible* because it is greater than the Betz limit.

18-60 The wind power potential of a wind turbine at a specified wind speed is to be determined.

Assumptions Wind flows steadily at the specified speed.

Properties The gas constant of air is $R = 0.287 \text{ kJ/kg}\cdot\text{K}$.

Analysis The density of air is determined from the ideal gas relation to be

$$\rho = \frac{P}{RT} = \frac{(96 \text{ kPa})}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(296 \text{ K})} = 1.130 \text{ kg/m}^3$$

The blade span area is

$$A = \pi D^2 / 4 = \pi (50 \text{ m})^2 / 4 = 1963 \text{ m}^2$$

Then the wind power potential is

$$\dot{W}_{\text{available}} = \frac{1}{2} \rho A V_1^3 = \frac{1}{2} (1.130 \text{ kg/m}^3)(1963 \text{ m}^2)(7.5 \text{ m/s})^3 \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = \mathbf{468 \text{ kW}}$$

18-61 Average wind power density values are given for two locations. The average wind speed in these locations are to be determined.

Properties The density of air is given to be $\rho = 1.18 \text{ kg/m}^3$.

Analysis The relation for wind power density is

$$\text{WPD} = \frac{1}{2} \rho V^3$$

Solving for wind velocity at the two locations, we obtain

$$\text{WPD}_1 = \frac{1}{2} \rho V_1^3 \longrightarrow 200 \text{ W/m}^2 = \frac{1}{2} (1.18 \text{ kg/m}^3) V_1^3 \longrightarrow V_1 = \mathbf{6.97 \text{ m/s}}$$

$$\text{WPD}_2 = \frac{1}{2} \rho V_2^3 \longrightarrow 400 \text{ W/m}^2 = \frac{1}{2} (1.18 \text{ kg/m}^3) V_2^3 \longrightarrow V_2 = \mathbf{8.79 \text{ m/s}}$$

18-62 A wind turbine is to generate power with a specified wind speed. The average electric power output, the amount of electricity produced, and the revenue generated are to be determined.

Assumptions Wind flows steadily at the specified speed.

Properties The density of air is given to be $\rho = 1.3 \text{ kg/m}^3$.

Analysis (a) The blade span area is

$$A = \pi D^2 / 4 = \pi (25 \text{ m})^2 / 4 = 490.9 \text{ m}^2$$

The wind power potential is

$$\dot{W}_{\text{available}} = \frac{1}{2} \rho A V_1^3 = \frac{1}{2} (1.3 \text{ kg/m}^3) (490.9 \text{ m}^2) (6 \text{ m/s})^3 \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 68.92 \text{ kW}$$

The electric power generated is

$$\dot{W}_{\text{electric}} = \eta_{\text{wt, overall}} \dot{W}_{\text{available}} = (0.34)(68.92 \text{ kW}) = \mathbf{23.43 \text{ kW}}$$

(b) The amount of electricity produced is determined from

$$W_{\text{electric}} = \dot{W}_{\text{electric}} \times \text{Operating hours} = (23.43 \text{ kW})(8000 \text{ h}) = \mathbf{187,500 \text{ kWh}}$$

(c) The revenue generated is

$$\text{Revenue} = W_{\text{electric}} \times \text{Unit price of electricity} = (187,500 \text{ kWh})(\$0.09/\text{kWh}) = \mathbf{\$16,900}$$

18-63 A wind turbine generates a certain amount of electricity during a week period. The average wind speed during this period is to be determined.

Properties The density of air is given to be $\rho = 1.16 \text{ kg/m}^3$.

Analysis The total operating hours during a week period is

$$\text{Operating hours} = 7 \times 24 \text{ h} = 168 \text{ h}$$

The average rate of electricity production is

$$\dot{W}_{\text{electric}} = \frac{W_{\text{electric}}}{\text{Operating hours}} = \frac{11,000 \text{ kWh}}{168 \text{ h}} = 65.48 \text{ kW}$$

The available wind power is

$$\dot{W}_{\text{available}} = \frac{\dot{W}_{\text{electric}}}{\eta_{\text{wt, overall}}} = \frac{65.48 \text{ kW}}{0.28} = 233.8 \text{ kW}$$

The blade span area is

$$A = \pi D^2 / 4 = \pi (40 \text{ m})^2 / 4 = 1257 \text{ m}^2$$

Finally, the average wind speed is determined from the definition of available wind power to be

$$\begin{aligned} \dot{W}_{\text{available}} &= \frac{1}{2} \rho A V^3 \\ 233.8 \text{ kW} &= \frac{1}{2} (1.16 \text{ kg/m}^3) (1257 \text{ m}^2) V^3 \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) \\ V &= \mathbf{6.85 \text{ m/s}} \end{aligned}$$

18-64E A wind turbine is to generate power with two specified wind speeds. The amount of electricity that can be produced by the turbine and the blade tip speed are to be determined.

Assumptions Wind flows steadily at the specified speeds.

Properties The density of air is given to be $\rho = 0.075 \text{ lbm/ft}^3$.

Analysis The blade span area is

$$A = \pi D^2 / 4 = \pi (185 \text{ ft})^2 / 4 = 26,880 \text{ ft}^2$$

The wind power potential at the wind speed of 16 ft/s is

$$\dot{W}_{\text{available},1} = \frac{1}{2} \rho A V_1^3 = \frac{1}{2} (0.075 \text{ lbm/ft}^3)(26,880 \text{ ft}^2)(16 \text{ ft/s})^3 \left(\frac{1 \text{ kW}}{23,730 \text{ lbm} \cdot \text{ft}^2/\text{s}^3} \right) = 174.0 \text{ kW}$$

The wind power potential at the wind speed of 24 ft/s is

$$\dot{W}_{\text{available},2} = \frac{1}{2} \rho A V_2^3 = \frac{1}{2} (0.075 \text{ lbm/ft}^3)(26,880 \text{ ft}^2)(24 \text{ ft/s})^3 \left(\frac{1 \text{ kW}}{23,730 \text{ lbm} \cdot \text{ft}^2/\text{s}^3} \right) = 587.2 \text{ kW}$$

The overall wind turbine efficiency at a wind speed of 16 ft/s is

$$\eta_{\text{wt,overall},1} = \eta_{\text{wt},1} \eta_{\text{gen}} = (0.30)(0.93) = 0.2790$$

The overall wind turbine efficiency at a wind speed of 24 ft/s is

$$\eta_{\text{wt,overall},2} = \eta_{\text{wt},2} \eta_{\text{gen}} = (0.35)(0.93) = 0.3255$$

The electric power generated at a wind speed of 16 ft/s is

$$\dot{W}_{\text{electric},1} = \eta_{\text{wt,overall},1} \dot{W}_{\text{available},1} = (0.2790)(174.0 \text{ kW}) = 48.54 \text{ kW}$$

The electric power generated at a wind speed of 24 ft/s is

$$\dot{W}_{\text{electric},2} = \eta_{\text{wt,overall},2} \dot{W}_{\text{available},2} = (0.3255)(587.2 \text{ kW}) = 191.1 \text{ kW}$$

The amount of electricity produced at a wind speed of 16 ft/s is

$$W_{\text{electric},1} = \dot{W}_{\text{electric},1} \times \text{Operating hours}_1 = (48.54 \text{ kW})(3000 \text{ h}) = 145,630 \text{ kWh}$$

The amount of electricity produced at a wind speed of 24 ft/s is

$$W_{\text{electric},2} = \dot{W}_{\text{electric},2} \times \text{Operating hours}_2 = (191.1 \text{ kW})(4000 \text{ h}) = 764,560 \text{ kWh}$$

The total amount of electricity produced is

$$W_{\text{electric,total}} = W_{\text{electric},1} + W_{\text{electric},2} = 145,630 + 764,560 = \mathbf{910,000 \text{ kWh}}$$

Noting that the tip of blade travels a distance of πD per revolution, the tip velocity of the turbine blade for a rotational speed of n becomes

$$V_{\text{tip}} = \pi D n = \pi (185 \text{ ft}) (15 / \text{min}) \left(\frac{1 \text{ min}}{60 \text{ s}} \right) \left(\frac{1 \text{ mi/h}}{1.46667 \text{ ft/s}} \right) = \mathbf{99.1 \text{ mph}}$$

18-65E Air velocities at the inlet and exit of a turbine are given. The wind turbine efficiency is to be determined when the frictional effects are neglected.

Assumptions Wind flows steadily at the specified speeds.

Analysis The wind turbine efficiency can be determined from Eq. 18-44 to be

$$V_2 = V_1 \sqrt{1 - \eta_{wt}}$$
$$19.5 \text{ ft/s} = (25 \text{ ft/s}) \sqrt{1 - \eta_{wt}}$$
$$\eta_{wt} = 0.3916 = \mathbf{39.2\text{percent}}$$

Hydropower

18-66C A water pump increases the pressure of water by supplying mechanical energy. A hydroturbine converts potential energy of water into mechanical shaft work and the pressure of water decreases across the turbine.

18-67C The maximum work that can be produced by this turbine is determined from

$$w_{\max} = (P_1 - P_2)/\rho$$

where ρ is the density of water.

18-68C We are usually more interested in the overall efficiency of turbine-generator combination rather than the turbine efficiency because a turbine is usually packaged together with its generator and it is much easier to measure the electric power output from the generator compared to shaft power output from the turbine.

18-69C No, we do not agree. The limitation that a machine cannot have an efficiency of 100 percent even in the absence of irreversibilities holds for heat engines which convert heat to work. A hydraulic turbine is not a heat engine as it converts mechanical energy into work and the upper limit for its efficiency is 100 percent.

18-70C No, we do not agree. A wind turbine converts kinetic energy of air into work and the Betz limit is due to the fact that the velocity of air at the wind turbine exit cannot be zero to maintain the flow. A hydraulic turbine, on the other hand, converts potential energy of water into work and the water velocities just upstream and downstream of the turbine are essentially equal to each other. Therefore, the upper limit for the efficiency of a hydraulic turbine is 100 percent.

18-71C The overall efficiency of a hydroelectric power plant can be expressed as

$$\eta_{\text{plant}} = \eta_{\text{generator}} \times \eta_{\text{turbine}} \times \eta_{\text{piping}}$$

Substituting the definition of each efficiency, we obtain

$$\begin{aligned} \eta_{\text{plant}} &= \eta_{\text{generator}} \eta_{\text{turbine}} \eta_{\text{piping}} \\ &= \left(\frac{\dot{W}_{\text{electric}}}{\dot{W}_{\text{shaft}}} \right) \left(\frac{\dot{W}_{\text{shaft}}}{\dot{W}_{\text{max}} - \dot{E}_{\text{mech, loss, piping}}} \right) \left(1 - \frac{\dot{E}_{\text{mech, loss, piping}}}{\dot{W}_{\text{max}}} \right) \\ &= \left(\frac{\dot{W}_{\text{electric}}}{\dot{W}_{\text{shaft}}} \right) \left[\frac{\dot{W}_{\text{shaft}}}{\dot{W}_{\text{max}} (1 - \dot{E}_{\text{mech, loss, piping}}/\dot{W}_{\text{max}})} \right] \left(1 - \frac{\dot{E}_{\text{mech, loss, piping}}}{\dot{W}_{\text{max}}} \right) \\ &= \frac{\dot{W}_{\text{electric}}}{\dot{W}_{\text{max}}} \end{aligned}$$

Therefore, the overall efficiency of a hydroelectric power plant is defined as the electrical power output divided by the maximum power potential.

18-72C There are two basic types of dynamic turbine—*impulse* and *reaction*. Comparing the two power-producing dynamic turbines, impulse turbines require a *higher head*, but can operate with a *smaller volume flow rate*. Reaction turbines can operate with much *less head*, but require a *higher volume flow rate*.

18-73 The power that can be produced by an ideal turbine from a large dam is to be determined.

Assumptions 1 The flow is steady. 2 Water levels at the reservoir and the discharge site remain constant.

Properties The density of water is taken to be $\rho = 1000 \text{ kg/m}^3 = 1 \text{ kg/L}$.

Analysis The total mechanical energy the water in a dam possesses is equivalent to the potential energy of water at the free surface of the dam (relative to free surface of discharge water), and it can be converted to work entirely for an ideal operation. Therefore, the maximum power that can be generated is equal to potential energy of the water. Noting that the mass flow rate is $\dot{m} = \rho\dot{V}$, the maximum power is determined from

$$\begin{aligned}\dot{W}_{\max} &= \dot{m}gH_{\text{gross}} = \rho\dot{V}gH_{\text{gross}} \\ &= (1 \text{ kg/L})(1500 \text{ L/s})(9.81 \text{ m/s}^2)(65 \text{ m}) \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) \\ &= \mathbf{15.94 \text{ kW}}\end{aligned}$$

18-74 The pressures just upstream and downstream of a hydraulic turbine are given. The maximum work and the flow rate of water for a given power are to be determined.

Assumptions 1 The flow is steady. 2 Water levels at the reservoir and the discharge site remain constant.

Properties The density of water is taken to be $\rho = 1000 \text{ kg/m}^3 = 1 \text{ kg/L}$.

Analysis The maximum work per unit mass of water flow is determined from

$$w_{\max} = \frac{P_1 - P_2}{\rho} = \frac{(1025 - 100) \text{ kPa}}{1000 \text{ kg/m}^3} \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) = \mathbf{1.225 \text{ kJ/kg}}$$

The flow rate of water is

$$\begin{aligned}\dot{W}_{\max} &= \dot{m}w_{\max} = \rho\dot{V}w_{\max} \\ \dot{V} &= \frac{\dot{W}_{\max}}{\rho w_{\max}} = \frac{100 \text{ kJ/s}}{(1 \text{ kg/L})(1.225 \text{ kJ/kg})} \left(\frac{60 \text{ s}}{1 \text{ min}} \right) \\ &= \mathbf{4898 \text{ L/min}}\end{aligned}$$

18-75 The efficiency of a hydraulic turbine is to be determined.

Assumptions **1** The flow is steady. **2** Water levels at the reservoir and the discharge site remain constant.

Properties The density of water is taken to be $\rho = 1000 \text{ kg/m}^3 = 1 \text{ kg/L}$.

Analysis The total mechanical energy the water in a dam possesses is equivalent to the potential energy of water at the free surface of the dam (relative to free surface of discharge water), and it can be converted to work entirely for an ideal operation. Therefore, the maximum power that can be generated is equal to potential energy of the water. Noting that the mass flow rate is $\dot{m} = \rho\dot{V}$, the maximum power is determined from

$$\begin{aligned}\dot{W}_{\max} &= \dot{m}gH_{\text{gross}} = \rho\dot{V}gH_{\text{gross}} \\ &= (1 \text{ kg/L})(11,500 \text{ L/min})\left(\frac{1 \text{ min}}{60 \text{ s}}\right)(9.81 \text{ m/s}^2)(160 \text{ m})\left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2}\right) \\ &= 300.8 \text{ kW}\end{aligned}$$

The turbine efficiency is determined from its definition to be

$$\eta_{\text{turbine}} = \frac{\dot{W}_{\text{shaft}}}{\dot{W}_{\max}} = \frac{250 \text{ kW}}{300.8 \text{ kW}} = 0.831 = \mathbf{83.1\text{percent}}$$

18-76 A hydraulic turbine-generator unit produces power from a dam. The overall efficiency of the turbine-generator unit, the turbine efficiency, and the power losses due to inefficiencies in the turbine and the generator are to be determined.

Assumptions 1 The flow is steady. 2 Water levels at the reservoir and the discharge site remain constant.

Properties The density of water is taken to be $\rho = 1000 \text{ kg/m}^3 = 1 \text{ kg/L}$.

Analysis (a) The total mechanical energy the water in a dam possesses is equivalent to the potential energy of water at the free surface of the dam (relative to free surface of discharge water), and it can be converted to work entirely for an ideal operation. Therefore, the maximum power that can be generated is equal to potential energy of the water. Noting that the mass flow rate is $\dot{m} = \rho \dot{V}$, the maximum power is determined from

$$\begin{aligned}\dot{W}_{\max} &= \dot{m}gH_{\text{gross}} = \rho \dot{V}gH_{\text{gross}} \\ &= (1 \text{ kg/L})(1020 \text{ L/s})(9.81 \text{ m/s}^2)(75 \text{ m}) \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) \\ &= 750.5 \text{ kW}\end{aligned}$$

The overall efficiency of turbine-generator unit is determined from its definition to be

$$\eta_{\text{turbine-generator}} = \frac{\dot{W}_{\text{electric}}}{\dot{W}_{\max}} = \frac{630 \text{ kW}}{750.5 \text{ kW}} = 0.8395 = \mathbf{84.0\text{percent}}$$

(b) The turbine efficiency is determine from

$$\eta_{\text{turbine}} = \frac{\eta_{\text{turbine-generator}}}{\eta_{\text{generator}}} = \frac{0.8395}{0.96} = 0.8745 = \mathbf{87.5\text{percent}}$$

(c) The shaft power output from the turbine is

$$\dot{W}_{\text{shaft}} = \frac{\dot{W}_{\text{electric}}}{\eta_{\text{generator}}} = \frac{630 \text{ kW}}{0.96} = 656.3 \text{ kW}$$

Finally, the power losses due to inefficiencies in the turbine and generator are

$$\dot{W}_{\text{loss,turbine}} = \dot{W}_{\max} - \dot{W}_{\text{shaft}} = 750.5 - 656.3 = \mathbf{94.2\text{kW}}$$

$$\dot{W}_{\text{loss,generator}} = \dot{W}_{\text{shaft}} - \dot{W}_{\text{electric}} = 656.3 - 630 = \mathbf{26.3\text{kW}}$$

18-77E The pressures just upstream and downstream of a hydraulic turbine are given. The shaft power output from the turbine and the height of the reservoir are to be determined.

Assumptions 1 The flow is steady. 2 Water levels at the reservoir and the discharge site remain constant.

Properties The density of water is taken to be $\rho = 62.4 \text{ lbm/ft}^3$.

Analysis (a) The maximum work per unit mass of water flow is determined from

$$\dot{W}_{\max} = \dot{m} \frac{P_1 - P_2}{\rho} = (280 \text{ lbm/s}) \frac{(95 - 15) \text{ psia}}{62.4 \text{ lbm/ft}^3} \left(\frac{1 \text{ Btu}}{5.40395 \text{ psia} \cdot \text{ft}^3} \right) \left(\frac{1 \text{ kJ}}{0.94782 \text{ Btu}} \right) = 70.09 \text{ kW}$$

The shaft power is

$$\dot{W}_{\text{shaft}} = \eta_{\text{turbine}} \dot{W}_{\max} = (0.86)(70.09 \text{ kW}) = \mathbf{60.3 \text{ kW}}$$

(b) The height of the reservoir is determined from

$$\begin{aligned} \dot{W}_{\max} &= \dot{m}gh \\ h &= \frac{\dot{W}_{\max}}{\dot{m}g} = \frac{70.09 \text{ kW}}{(280 \text{ lbm/s})(32.2 \text{ ft/s}^2)} \left(\frac{1 \text{ kW}}{23,730 \text{ lbm} \cdot \text{ft}^2/\text{s}^3} \right) = \mathbf{185 \text{ ft}} \end{aligned}$$

18-78 The irreversible head losses in the penstock and its inlet and those after the exit of the draft tube are given. The power loss due to irreversible head loss, the efficiency of the piping, and the electric power output are to be determined.

Assumptions 1 The flow is steady. 2 Water levels at the reservoir and the discharge site remain constant.

Properties The density of water is taken to be $\rho = 1000 \text{ kg/m}^3 = 1 \text{ kg/L}$.

Analysis (a) The power loss due to irreversible head loss is determined from

$$\begin{aligned}\dot{E}_{\text{loss,piping}} &= \rho \dot{V} g h_L \\ &= (1 \text{ kg/L})(4000/60 \text{ L/s})(9.81 \text{ m/s}^2)(7 \text{ m}) \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) \\ &= \mathbf{4.578 \text{ kW}}\end{aligned}$$

(b) The efficiency of the piping is determined from the head loss and gross head to be

$$\eta_{\text{piping}} = 1 - \frac{h_L}{H_{\text{gross}}} = 1 - \frac{7 \text{ m}}{140 \text{ m}} = 0.950 = \mathbf{95.0 \text{ percent}}$$

(c) The maximum power is determined from

$$\begin{aligned}\dot{W}_{\text{max}} &= \dot{m} g H_{\text{gross}} = \rho \dot{V} g H_{\text{gross}} \\ &= (1 \text{ kg/L})(4000/60 \text{ L/s})(9.81 \text{ m/s}^2)(140 \text{ m}) \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) \\ &= \mathbf{91.56 \text{ kW}}\end{aligned}$$

The overall efficiency of the hydroelectric plant is

$$\eta_{\text{plant}} = \eta_{\text{turbine-generator}} \eta_{\text{piping}} = (0.84)(0.950) = 0.798$$

The electric power output is

$$\dot{W}_{\text{electric}} = \eta_{\text{plant}} \dot{W}_{\text{max}} = (0.798)(91.56 \text{ kW}) = \mathbf{73.1 \text{ kW}}$$

18-79 Various efficiencies of a hydroelectric power plant are given. The overall efficiency of the plant and the electric power output are to be determined.

Assumptions 1 The flow is steady. 2 Water levels at the reservoir and the discharge site remain constant.

Properties The density of water is taken to be $\rho = 1000 \text{ kg/m}^3 = 1 \text{ kg/L}$.

Analysis The overall efficiency of the hydroelectric plant is determined from

$$\eta_{\text{plant}} = \eta_{\text{turbine}}\eta_{\text{generator}}\eta_{\text{piping}} = (0.87)(0.97)(0.98) = 0.827 = \mathbf{82.7\text{percent}}$$

The maximum power is determined from

$$\begin{aligned}\dot{W}_{\text{max}} &= \dot{m}gH_{\text{gross}} = \rho\dot{V}gH_{\text{gross}} \\ &= (1 \text{ kg/L})(600 \text{ L/s})(9.81 \text{ m/s}^2)(220 \text{ m})\left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2}\right) \\ &= 1295 \text{ kW}\end{aligned}$$

The electric power output is

$$\dot{W}_{\text{electric}} = \eta_{\text{plant}}\dot{W}_{\text{max}} = (0.827)(1295 \text{ kW}) = \mathbf{1071 \text{ kW}}$$

18-80 A hydroelectric power plant operating 80 percent of the time is considered. The revenue that can be generated in a year is to be determined.

Assumptions 1 The flow is steady. 2 Water levels at the reservoir and the discharge site remain constant.

Properties The density of water is taken to be $\rho = 1000 \text{ kg/m}^3 = 1 \text{ kg/L}$.

Analysis The maximum power for one turbine is determined from

$$\begin{aligned}\dot{W}_{\text{max}} &= \dot{m}gH_{\text{gross}} = \rho\dot{V}gH_{\text{gross}} \\ &= (1 \text{ kg/L})(3300/60 \text{ L/s})(9.81 \text{ m/s}^2)(150 \text{ m})\left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2}\right) \\ &= 80.93 \text{ kW}\end{aligned}$$

The electric power output is

$$\dot{W}_{\text{electric}} = \eta_{\text{plant}}\dot{W}_{\text{max}} = (0.90)(80.93 \text{ kW}) = 72.84 \text{ kW}$$

Noting that the plant operates 80 percent of the time, the operating hours in one year is

$$\text{Operating hours} = 0.80 \times 365 \times 24 = 7008 \text{ h}$$

The amount of electricity produced per year by one turbine is

$$W_{\text{electric}} = \dot{W}_{\text{electric}} \times \text{Operating hours} = (72.84 \text{ kW})(7008 \text{ h}) = 510,500 \text{ kWh}$$

Finally, the revenue generated by 18 such turbines is

$$\text{Revenue} = n_{\text{turbine}} \times W_{\text{electric}} \times \text{Unit price of electricity} = (18)(510,500 \text{ kWh})(\$0.095/\text{kWh}) = \mathbf{\$873,000}$$

Geothermal Energy

18-81C One common classification of geothermal resources is based on their temperature.

High temperature resource: $T > 150^{\circ}\text{C}$

Medium temperature resource: $90^{\circ}\text{C} < T < 150^{\circ}\text{C}$

Low temperature resource: $T < 90^{\circ}\text{C}$

18-82C There are several options for utilizing the thermal energy produced from geothermal energy systems: Electricity production, space heating and cooling, cogeneration, and heat pump. The most common use of geothermal energy is electricity production.

18-83C The quality or work potential of geothermal resources is proportional to temperature of the source. The maximum thermal efficiency of a geothermal power plant utilizing a source at 110°C and a sink temperature of 25°C is $\eta_{\text{th,max}} = 1 - (25+273)/(110+273) = 0.222 = 22.2\%$. The actual efficiency of the proposed power plant will be much lower than this value. It is very unlikely that a power plant investment on this site will be feasible. It makes both thermodynamic and economic sense to use this source for heating or cooling applications.

18-84C Approximate temperature requirements for geothermal applications are

Electricity production $\Rightarrow T > 120^{\circ}\text{C}$

Cooling $\Rightarrow T > 95^{\circ}\text{C}$

Heating $\Rightarrow T > 50^{\circ}\text{C}$

18-85C Ground-source heat pumps are also called geothermal heat pumps as they utilize the heat of the earth. These systems use higher ground temperatures in winter for heat absorption (heating mode) and cooler ground temperatures in summer for heat rejection (cooling mode), and this is the reason for higher COPs.

18-86C The purpose of flashing process is to convert saturated or compressed liquid to a liquid-vapor mixture. The resulting mixture is sent to turbine for power production. The flashing process is a constant-enthalpy process. Both pressure and temperature decreases during this process.

18-87C This is a liquid geothermal resource at a relatively low temperature and a binary cycle is best suited for power generation.

18-88E A geothermal site contains saturated mixture of geothermal water at 300°F. The maximum thermal efficiency and the maximum amount of power are to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible. **3** Water properties will be used for geothermal fluid.

Analysis The maximum thermal efficiency can be determined from the Carnot efficiency relation using the geothermal source and dead state temperatures:

$$\eta_{\text{th,max}} = 1 - \frac{T_L}{T_H} = 1 - \frac{(80 + 460) \text{ R}}{(300 + 460) \text{ R}} = 0.2895 = \mathbf{29.0\text{percent}}$$

The enthalpy and entropy values of geothermal water at the wellhead state and dead state are obtained from steam tables:

$$\left. \begin{array}{l} T_1 = 300^\circ\text{F} \\ x_1 = 0.35 \end{array} \right\} \begin{array}{l} h_1 = 588.31 \text{ Btu/lbm} \\ s_1 = 0.8566 \text{ Btu/lbm} \cdot \text{R} \end{array} \quad (\text{Table A-4E})$$

$$\left. \begin{array}{l} T_0 = 80^\circ\text{F} \\ x_0 = 0 \end{array} \right\} \begin{array}{l} h_0 = 48.07 \text{ Btu/lbm} \\ s_0 = 0.09328 \text{ Btu/lbm} \cdot \text{R} \end{array} \quad (\text{Table A-4E})$$

The maximum power potential is equal to the exergy of the geothermal water available at the wellhead:

$$\begin{aligned} \dot{W}_{\text{max}} &= \dot{X}_1 = \dot{m}_1 [h_1 - h_0 - T_0 (h_1 - h_0)] \\ &= (100 \text{ lbm/s}) [(588.31 - 48.07) \text{ Btu/lbm} - (0.8566 - 0.09328) \text{ Btu/lbm} \cdot \text{R}] \left(\frac{1 \text{ kW}}{0.94782 \text{ Btu/s}} \right) \\ &= \mathbf{13,500 \text{ kW}} \end{aligned}$$

18-89 A residential district is to be heated by geothermal water in winter. The revenue generated due to selling geothermal heat is to be determined.

Assumptions 1 Steady operating conditions exist. **2** Kinetic and potential energy changes are negligible. **3** Water properties will be used for geothermal fluid.

Properties The specific heat of water at room temperature is $c_p = 4.18 \text{ kJ/kg} \cdot ^\circ\text{C}$.

Analysis The rate of geothermal heat supplied to the district is determined from

$$\dot{Q}_{\text{heat}} = \dot{m} c_p (T_1 - T_2) = (70 \text{ kg/s})(4.18 \text{ kJ/kg} \cdot ^\circ\text{C})(90 - 50)^\circ\text{C} = 11,704 \text{ kW}$$

The amount of heat supplied for a period of 2500 hours is

$$Q_{\text{heat}} = \dot{Q}_{\text{heat}} \times \text{Operating hours} = (11,704 \text{ kJ/s})(2500 \times 3600 \text{ s}) = 1.053 \times 10^{11} \text{ kJ}$$

The revenue generated by selling the geothermal heat is

$$\begin{aligned} \text{Revenue} &= Q_{\text{heat}} \times \text{Unit price of geothermal heat} \\ &= (1.053 \times 10^{11} \text{ kJ})(\$1.2 \times 10^{-5} / \text{kJ}) \\ &= \$1.264 \times 10^6 \\ &= \mathbf{\$1.264 \text{ millions}} \end{aligned}$$

18-90E Geothermal water is to be used for space cooling. The potential revenue that can be generated by this geothermal cooling system is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible. 3 Water properties will be used for geothermal fluid.

Properties The specific heat of water at room temperature is $c_p = 1.0 \text{ Btu/lbm}\cdot^\circ\text{F}$.

Analysis The rate of heat transfer in the generator of the absorption system is

$$\dot{Q}_{\text{gen}} = \dot{m}c_p(T_1 - T_2) = (86,000 \text{ lbm/h})(1.0 \text{ Btu/lbm}\cdot^\circ\text{F})(210 - 180)^\circ\text{F} = 2.580 \times 10^6 \text{ Btu/h}$$

Using the definition of the COP of an absorption cooling system, the rate of cooling is determined to be

$$\text{COP}_{\text{ABS}} = \frac{\dot{Q}_{\text{cool}}}{\dot{Q}_{\text{gen}}} \longrightarrow \dot{Q}_{\text{cool}} = \text{COP} \times \dot{Q}_{\text{gen}} = (0.70)(2.580 \times 10^6 \text{ Btu/h}) \left(\frac{1 \text{ kW}}{3412.14 \text{ Btu/h}} \right) = 529.3 \text{ kW}$$

If a conventional cooling system with a COP of 2.3 is used for this cooling, the power input would be

$$\text{COP} = \frac{\dot{Q}_{\text{cool}}}{\dot{W}_{\text{in}}} \longrightarrow \dot{W}_{\text{in}} = \frac{\dot{Q}_{\text{cool}}}{\text{COP}} = \frac{529.3 \text{ kW}}{2.3} = 230.1 \text{ kW}$$

The electricity consumption for a period of 2000 hours is

$$W_{\text{in}} = \dot{W}_{\text{in}} \times \text{Operating hours} = (230.1 \text{ kW})(2000 \text{ h}) = 460,250 \text{ kWh}$$

At a discount of 20 percent, the revenue generated by selling the geothermal cooling is

$$\begin{aligned} \text{Revenue} &= (1 - f_{\text{discount}}) \times W_{\text{in}} \times \text{Unit price of electricity} \\ &= (1 - 0.2)(460,250 \text{ kWh})(\$0.14/\text{kWh}) \\ &= \mathbf{\$51,550} \end{aligned}$$

18-91 A single-flash geothermal power plant uses hot geothermal water at 230°C as the heat source. The mass flow rate of steam through the turbine, the isentropic efficiency of the turbine, the power output from the turbine, and the thermal efficiency of the plant are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) We use properties of water for geothermal water (Tables A-4 through A-6)

$$\left. \begin{array}{l} T_1 = 230^\circ\text{C} \\ x_1 = 0 \end{array} \right\} h_1 = 990.14 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_2 = 500 \text{ kPa} \\ h_2 = h_1 = 990.14 \text{ kJ/kg} \end{array} \right\} x_2 = \frac{h_2 - h_f}{h_{fg}} = \frac{990.14 - 640.09}{2108} = 0.1661$$

The mass flow rate of steam through the turbine is

$$\dot{m}_3 = x_2 \dot{m}_1 = (0.1661)(230 \text{ kg/s}) = \mathbf{38.20 \text{ kg/s}}$$

(b) Turbine:

$$\left. \begin{array}{l} P_3 = 500 \text{ kPa} \\ x_3 = 1 \end{array} \right\} \begin{array}{l} h_3 = 2748.1 \text{ kJ/kg} \\ s_3 = 6.8207 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_4 = 10 \text{ kPa} \\ s_4 = s_3 \end{array} \right\} h_{4s} = 2160.3 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_4 = 10 \text{ kPa} \\ x_4 = 0.90 \end{array} \right\} h_4 = h_f + x_4 h_{fg} = 191.81 + (0.90)(2392.1) = 2344.7 \text{ kJ/kg}$$

$$\eta_T = \frac{h_3 - h_4}{h_3 - h_{4s}} = \frac{2748.1 - 2344.7}{2748.1 - 2160.3} = \mathbf{0.686}$$

(c) The power output from the turbine is

$$\dot{W}_{T,\text{out}} = \dot{m}_3 (h_3 - h_4) = (38.20 \text{ kJ/kg})(2748.1 - 2344.7) \text{ kJ/kg} = \mathbf{15,410 \text{ kW}}$$

(d) We use saturated liquid state at the standard temperature for dead state enthalpy

$$\left. \begin{array}{l} T_0 = 25^\circ\text{C} \\ x_0 = 0 \end{array} \right\} h_0 = 104.83 \text{ kJ/kg}$$

$$\dot{E}_{\text{in}} = \dot{m}_1 (h_1 - h_0) = (230 \text{ kJ/kg})(990.14 - 104.83) \text{ kJ/kg} = 203,622 \text{ kW}$$

$$\eta_{\text{th}} = \frac{\dot{W}_{T,\text{out}}}{\dot{E}_{\text{in}}} = \frac{15,410}{203,622} = 0.0757 = \mathbf{7.6\%}$$

18-92 A double-flash geothermal power plant uses hot geothermal water at 230°C as the heat source. The temperature of the steam at the exit of the second flash chamber, the power produced from the second turbine, and the thermal efficiency of the plant are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) We use properties of water for geothermal water (Tables A-4 through A-6)

$$\left. \begin{array}{l} T_1 = 230^\circ\text{C} \\ x_1 = 0 \end{array} \right\} h_1 = 990.14 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_2 = 500 \text{ kPa} \\ h_2 = h_1 = 990.14 \text{ kJ/kg} \end{array} \right\} x_2 = 0.1661$$

$$\dot{m}_3 = x_2 \dot{m}_1 = (0.1661)(230 \text{ kg/s}) = 38.20 \text{ kg/s}$$

$$\dot{m}_6 = \dot{m}_1 - \dot{m}_3 = 230 - 0.1661 = 191.80 \text{ kg/s}$$

$$\left. \begin{array}{l} P_3 = 500 \text{ kPa} \\ x_3 = 1 \end{array} \right\} h_3 = 2748.1 \text{ kJ/kg}$$

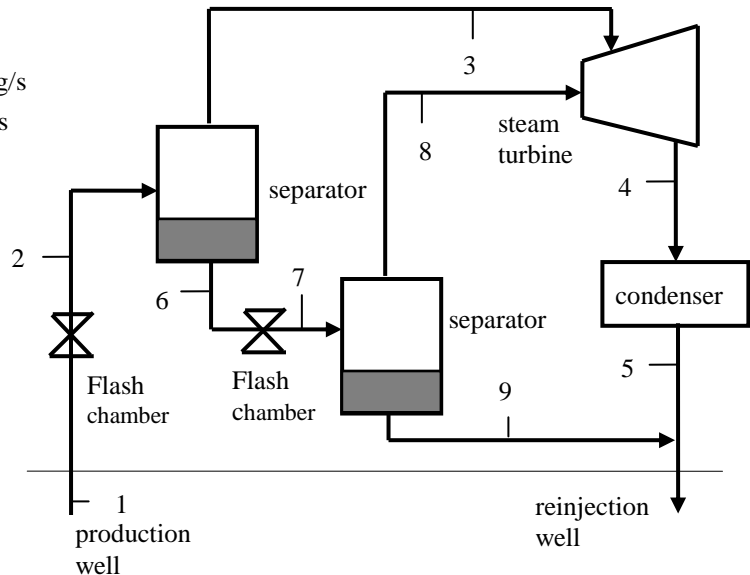

$$\left. \begin{array}{l} P_4 = 10 \text{ kPa} \\ x_4 = 0.90 \end{array} \right\} h_4 = 2344.7 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_6 = 500 \text{ kPa} \\ x_6 = 0 \end{array} \right\} h_6 = 640.09 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_7 = 150 \text{ kPa} \\ h_7 = h_6 \end{array} \right\} T_7 = \mathbf{111.35^\circ\text{C}}$$

$$\left. \begin{array}{l} x_7 = 0.0777 \end{array} \right\}$$

$$\left. \begin{array}{l} P_8 = 150 \text{ kPa} \\ x_8 = 1 \end{array} \right\} h_8 = 2693.1 \text{ kJ/kg}$$

(b) The mass flow rate at the lower stage of the turbine is

$$\dot{m}_8 = x_7 \dot{m}_6 = (0.0777)(191.80 \text{ kg/s}) = 14.90 \text{ kg/s}$$

The power outputs from the high and low pressure stages of the turbine are

$$\dot{W}_{T1,\text{out}} = \dot{m}_3(h_3 - h_4) = (38.20 \text{ kJ/kg})(2748.1 - 2344.7) \text{ kJ/kg} = 15,410 \text{ kW}$$

$$\dot{W}_{T2,\text{out}} = \dot{m}_8(h_8 - h_4) = (14.90 \text{ kJ/kg})(2693.1 - 2344.7) \text{ kJ/kg} = \mathbf{5191 \text{ kW}}$$

(c) We use saturated liquid state at the standard temperature for the dead state enthalpy

$$\left. \begin{array}{l} T_0 = 25^\circ\text{C} \\ x_0 = 0 \end{array} \right\} h_0 = 104.83 \text{ kJ/kg}$$

$$\dot{E}_{\text{in}} = \dot{m}_1(h_1 - h_0) = (230 \text{ kg/s})(990.14 - 104.83) \text{ kJ/kg} = 203,621 \text{ kW}$$

$$\eta_{\text{th}} = \frac{\dot{W}_{T,\text{out}}}{\dot{E}_{\text{in}}} = \frac{15,410 + 5193}{203,621} = 0.101 = \mathbf{10.1\%}$$

18-93 A combined flash-binary geothermal power plant uses hot geothermal water at 230°C as the heat source. The mass flow rate of isobutane in the binary cycle, the net power outputs from the steam turbine and the binary cycle, and the thermal efficiencies for the binary cycle and the combined plant are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis (a) We use properties of water for geothermal water (Tables A-4 through A-6)

$$\left. \begin{array}{l} T_1 = 230^\circ\text{C} \\ x_1 = 0 \end{array} \right\} h_1 = 990.14 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_2 = 500 \text{ kPa} \\ h_2 = h_1 = 990.14 \text{ kJ/kg} \end{array} \right\} x_2 = 0.1661$$

$$\dot{m}_3 = x_2 \dot{m}_1 = (0.1661)(230 \text{ kg/s}) = 38.20 \text{ kg/s}$$

$$\dot{m}_6 = \dot{m}_1 - \dot{m}_3 = 230 - 38.20 = 191.80 \text{ kg/s}$$

$$\left. \begin{array}{l} P_3 = 500 \text{ kPa} \\ x_3 = 1 \end{array} \right\} h_3 = 2748.1 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_4 = 10 \text{ kPa} \\ x_4 = 0.90 \end{array} \right\} h_4 = 2344.7 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_6 = 500 \text{ kPa} \\ x_6 = 0 \end{array} \right\} h_6 = 640.09 \text{ kJ/kg}$$

$$\left. \begin{array}{l} T_7 = 90^\circ\text{C} \\ x_7 = 0 \end{array} \right\} h_7 = 377.04 \text{ kJ/kg}$$

The isobutane properties are obtained from EES:

$$\left. \begin{array}{l} P_8 = 3250 \text{ kPa} \\ T_8 = 145^\circ\text{C} \end{array} \right\} h_8 = 755.05 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_9 = 400 \text{ kPa} \\ T_9 = 80^\circ\text{C} \end{array} \right\} h_9 = 691.01 \text{ kJ/kg}$$

$$\left. \begin{array}{l} P_{10} = 400 \text{ kPa} \\ x_{10} = 0 \end{array} \right\} \begin{array}{l} h_{10} = 270.83 \text{ kJ/kg} \\ v_{10} = 0.001839 \text{ m}^3/\text{kg} \end{array}$$

$$w_{p,\text{in}} = v_{10}(P_{11} - P_{10})/\eta_p$$

$$= (0.001839 \text{ m}^3/\text{kg})(3250 - 400) \text{ kPa} \left(\frac{1 \text{ kJ}}{1 \text{ kPa} \cdot \text{m}^3} \right) / 0.90$$

$$= 5.82 \text{ kJ/kg.}$$

$$h_{11} = h_{10} + w_{p,\text{in}} = 270.83 + 5.82 = 276.65 \text{ kJ/kg}$$

An energy balance on the heat exchanger gives

$$\dot{m}_6 (h_6 - h_7) = \dot{m}_{\text{iso}} (h_8 - h_{11})$$

$$(191.81 \text{ kg/s})(640.09 - 377.04) \text{ kJ/kg} = \dot{m}_{\text{iso}} (755.05 - 276.65) \text{ kJ/kg} \longrightarrow \dot{m}_{\text{iso}} = \mathbf{105.46 \text{ kg/s}}$$

(b) The power outputs from the steam turbine and the binary cycle are

$$\dot{W}_{\text{T,steam}} = \dot{m}_3 (h_3 - h_4) = (38.19 \text{ kg/s})(2748.1 - 2344.7) \text{ kJ/kg} = \mathbf{15,410 \text{ kW}}$$

$$\dot{W}_{\text{T,iso}} = \dot{m}_{\text{iso}} (h_8 - h_9) = (105.46 \text{ kg/s})(755.05 - 691.01) \text{ kJ/kg} = 6753 \text{ kW}$$

$$\dot{W}_{\text{net,binary}} = \dot{W}_{\text{T,iso}} - \dot{m}_{\text{iso}} w_{p,\text{in}} = 6753 - (105.46 \text{ kg/s})(5.82 \text{ kJ/kg}) = \mathbf{6139 \text{ kW}}$$

(c) The thermal efficiencies of the binary cycle and the combined plant are

$$\dot{Q}_{\text{in,binary}} = \dot{m}_{\text{iso}}(h_8 - h_{11}) = (105.46 \text{ kJ/kg})(755.05 - 276.65) \text{ kJ/kg} = 50,454 \text{ kW}$$

$$\eta_{\text{th,binary}} = \frac{\dot{W}_{\text{net,binary}}}{\dot{Q}_{\text{in,binary}}} = \frac{6139}{50,454} = 0.122 = \mathbf{12.2\%}$$

$$\left. \begin{array}{l} T_0 = 25^\circ\text{C} \\ x_0 = 0 \end{array} \right\} h_0 = 104.83 \text{ kJ/kg}$$

$$\dot{E}_{\text{in}} = \dot{m}_1(h_1 - h_0) = (230 \text{ kJ/kg})(990.14 - 104.83) \text{ kJ/kg} = 203,622 \text{ kW}$$

$$\eta_{\text{th,plant}} = \frac{\dot{W}_{\text{T,steam}} + \dot{W}_{\text{net,binary}}}{\dot{E}_{\text{in}}} = \frac{15,410 + 6139}{203,622} = 0.106 = \mathbf{10.6\%}$$

18-94 A binary geothermal cogeneration plant produces power and provides space heating. The rate of space heating provided by the system, the mass flow rate of water used for space heating, the thermal efficiency of the power plant, and the utilization factor for the entire cogeneration plant are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Properties The specific heat of water at room temperature is $c_p = 4.18 \text{ kJ/kg}\cdot^\circ\text{C}$.

Analysis (a) The rate of space heating provided by the system is determined from

$$\dot{Q}_{\text{heat}} = \dot{m}c_p(T_6 - T_7) = (175 \text{ kg/s})(4.18 \text{ kJ/kg}\cdot^\circ\text{C})(85 - 65)^\circ\text{C} = \mathbf{14,630 \text{ kW}}$$

The mass flow rate of fresh water is

$$\begin{aligned}\dot{Q}_{\text{heat}} &= \dot{m}_w c_p (T_9 - T_8) \\ 14,630 \text{ kW} &= \dot{m}_w (4.18 \text{ kJ/kg}\cdot^\circ\text{C})(75 - 50)^\circ\text{C} \\ \dot{m}_w &= \mathbf{140 \text{ kg/s}}\end{aligned}$$

(a) The rate of heat input to the power plant is

$$\dot{Q}_{\text{in}} = \dot{m}c_p(T_5 - T_6) = (175 \text{ kg/s})(4.18 \text{ kJ/kg}\cdot^\circ\text{C})(165 - 85)^\circ\text{C} = 58,520 \text{ kW}$$

The thermal efficiency of the power plant and the utilization factor of the cogeneration plant are determined from their definitions to be

$$\begin{aligned}\eta_{\text{th}} &= \frac{\dot{W}_{\text{out}}}{\dot{Q}_{\text{in}}} = \frac{6900 \text{ kW}}{58,520 \text{ kW}} = 0.1179 = \mathbf{11.8\%} \\ \varepsilon_u &= \frac{\dot{W}_{\text{out}} + \dot{Q}_{\text{heat}}}{\dot{Q}_{\text{in}}} = \frac{6900 \text{ kW} + 14,630 \text{ kW}}{58,520 \text{ kW}} = 0.3679 = \mathbf{36.8\%}\end{aligned}$$

18-95 A binary geothermal cogeneration plant produces power and provides space heating. The amount of money than can be made by selling geothermal heat is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Properties The specific heat of water at room temperature is $c_p = 4.18 \text{ kJ/kg}\cdot^\circ\text{C}$.

Analysis The amount of natural gas used to supply space heating at a rate of 14,630 kW is determined from

$$\text{Amount of natural gas} = \frac{\dot{Q}_{\text{heat}} \times \text{Operating hours}}{\eta_{\text{boiler}}} = \frac{(14,630 \text{ kJ/s})(4200 \times 3600 \text{ s})}{0.85} \left(\frac{1 \text{ therm}}{105,500 \text{ kJ}} \right) = 234,916 \text{ therms}$$

The revenue generated by selling the geothermal heat is

$$\begin{aligned}\text{Revenue} &= (1 - f_{\text{discount}}) \times \text{Amount of natural gas} \times \text{Unit price of natural gas} \\ &= (1 - 0.25)(234,916 \text{ therms})(\$1.3/\text{therm}) \\ &= \mathbf{\$229,000}\end{aligned}$$

Biomass Energy

18-96C Biomass is mostly produced from agriculture and forest products and residues, energy crops, and algae. Organic component of municipal and industrial wastes and the fuel produced from food processing waste such as used cooking oil are also considered biomass. Despite relatively long period of times involved in growing crops and trees, they can be re-grown by planting, and therefore biomass is considered to be a renewable energy source.

18-97C Growing of crops and trees as well as the conversion to liquid and gaseous fuels involves the consumption of energy in the form of electricity and fossil fuels such as coal, oil, and natural gas. The consumption of fossil fuels is accompanied by the pollutant and greenhouse emissions. Therefore, the renewability and cleanliness of biomass are not as good as other renewables such as solar, geothermal, or wind.

18-98C In **pyrolysis**, biomass is exposed to high temperatures without the presence of air, causing it to decompose.

18-99C The two most common biofuels are ethanol and biodiesel.

18-100C Ethanol has a higher heating value (HHV) of 29,710 kJ/kg while the higher heating value of biodiesel is about 40,700 kJ/kg. Since the heating value of biodiesel is higher, the car using biodiesel will get more mileage.

18-101C The higher heating value of biodiesel is about 40,700 kJ/kg, which is about 9 percent less than that of petroleum diesel (HHV = 44,800 kJ/kg). Since the heating value of petroleum diesel is higher, the car using petroleum diesel will get more mileage. Biodiesel could increase nitrogen oxides emissions compared to petroleum diesel while significantly reducing hydrocarbon, sulfur and carbon monoxide emissions.

18-102C Biogas usually consists of 50 to 80 percent methane (CH_4) and 20 to 50 percent carbon dioxide (CO_2) by volume. It also contains small amounts of hydrogen, carbon monoxide, and nitrogen. Biogas can be produced from biological waste such as animal manure, food waste, and agricultural waste.

18-103C An important class of biomass is produced by households as trash or garbage. This is referred to as **municipal solid waste** (MSW). MSW includes mostly organic materials such as paper, food scraps, wood, and yard trimmings but some fossil content such as plastic also exists. MSW does not include industrial, hazardous, or construction waste.

18-104C Recycling refers to recovery of useful materials such as paper, glass, plastic, and metals from the trash to use to make new products. **Composting**, on the other hand, refers to storing organic waste such as food scraps and yard trimmings under certain conditions to help it break down naturally. The resulting product can be used as a natural fertilizer.

18-105C In **waste to energy** (WTE) option, waste is burned directly for generating steam. This steam is run through a turbine to generate electricity. The second option is known as **landfill-gas-to-energy** (LFGTE), and it involves harvesting biogas (mostly methane) from the buried waste as it decomposes. Biogas is then used as the fuel in an internal combustion engine or gas turbine to generate electricity.

18-106 Sugar beet roots with certain sugar content are used to produce ethanol. The amount of ethanol that can be produced from 100 kg of sugar beet roots is to be determined.

Properties The molar masses of C, H₂, and O₂ are 12 kg/kmol, 2 kg/kmol, and 32 kg/kmol, respectively (Table A-1).

Analysis The molar mass of ethanol C₆H₁₂O₆ and sugar C₂H₅OH are

$$M_{\text{C}_6\text{H}_{12}\text{O}_6} = 6 \times 12 + 12 \times 2 + 6 \times 32 = 180 \text{ kg/kmol}$$

$$M_{\text{C}_2\text{H}_5\text{OH}} = 2 \times 12 + 5 \times 2 + 1 \times 32 = 46 \text{ kg/kmol}$$

The mass of sugar in 100 kg of sugar beet roots is

$$m_{\text{sugar}} = m_{\text{sugar}}^f \times m_{\text{beet}} = (0.20)(100 \text{ kg}) = 20 \text{ kg}$$

The ratio of mass of ethanol to the mass of sugar is obtained from the chemical reaction $\text{C}_6\text{H}_{12}\text{O}_6 \rightarrow 2 \text{C}_2\text{H}_5\text{OH} + 2 \text{CO}_2$ is

$$\frac{m_{\text{ethanol}}}{m_{\text{sugar}}} = \frac{2M_{\text{C}_6\text{H}_{12}\text{O}_6}}{M_{\text{C}_2\text{H}_5\text{OH}}} = \frac{(2 \times 180) \text{ kg}}{46 \text{ kg}} = 0.5111$$

The mass of the ethanol produced is

$$m_{\text{ethanol}} = m_{\text{sugar}} \frac{m_{\text{ethanol}}}{m_{\text{sugar}}} = (20 \text{ kg})(0.5111) = \mathbf{10.2 \text{ kg}}$$

18-107E Methanol is to replace gasoline in an internal combustion engine. The maximum power output from the engine with methanol as the fuel is to be estimated and the rates of gasoline and methanol consumptions are to be determined.

Assumptions 1 Combustion is complete. 2 The combustion products contain CO_2 , H_2O , O_2 , and N_2 only.

Properties The molar masses of C, H_2 , and O_2 are 12 lbm/lbmol, 2 lbm/lbmol, and 32 lbm/lbmol, respectively (Table A-1E). The lower heating values of gasoline and ethanol are 18,490 Btu/lbm and 8620 Btu/lbm, respectively.

Analysis The balanced reaction equation with stoichiometric air is

The stoichiometric coefficient a_{th} is determined from an O_2 balance:

$$0.5 + a_{\text{th}} = 1 + 1 \longrightarrow a_{\text{th}} = 1.5$$

Substituting,

Therefore, the air-fuel ratio for this stoichiometric reaction is

$$\text{AF} = \frac{m_{\text{air}}}{m_{\text{fuel}}} = \frac{(1.5 \times 4.76 \times 29) \text{ lbm}}{(1 \times 12 + 4 \times 1 + 1 \times 16) \text{ lbm}} = \frac{207.1 \text{ lbm}}{32 \text{ lbm}} = 6.471$$

For a given engine size (i.e., volume), the power produced is proportional to the heating value of the fuel and inversely proportional to the air-fuel ratio. The ratio of power produced by gasoline engine to that of methanol engine is expressed as

$$\frac{\dot{W}_{\text{gasoline}}}{\dot{W}_{\text{methanol}}} = \frac{\text{LHV}_{\text{gasoline}}}{\text{LHV}_{\text{methanol}}} \times \frac{\text{AF}_{\text{methanol}}}{\text{AF}_{\text{gasoline}}} = \left(\frac{18,490 \text{ Btu/lbm}}{8620 \text{ Btu/lbm}} \right) \left(\frac{6.471}{14.6} \right) = 0.9507$$

Then, the maximum power by the engine with ethanol as the fuel becomes

$$\dot{W}_{\text{methanol}} = \dot{W}_{\text{gasoline}} \frac{\dot{W}_{\text{methanol}}}{\dot{W}_{\text{gasoline}}} = \dot{W}_{\text{gasoline}} \frac{1}{0.9507} = \frac{200 \text{ hp}}{0.9507} = \mathbf{210.4 \text{ hp}}$$

The thermal efficiency of this engine is defined as the net power output divided by the rate of heat input, which is equal to the heat released by the combustion of fuel:

$$\eta_{\text{th}} = \frac{\dot{W}_{\text{out}}}{\dot{Q}_{\text{in}}} = \frac{\dot{W}_{\text{out}}}{\dot{m}_{\text{fuel}} \times \text{LHV} \times \eta_c}$$

Note that the lower heating value is used in the analysis of internal combustion engines since the water in the exhaust is normally in the vapor phase. Solving the above equation for the rates of gasoline and ethanol consumption, we obtain

$$\dot{m}_{\text{gasoline}} = \frac{\dot{W}_{\text{gasoline}}}{\eta_{\text{th}} \times \text{LHV}_{\text{gasoline}} \times \eta_c} = \frac{200 \text{ hp}}{(0.40)(18,490 \text{ Btu/lbm})(1)} \left(\frac{42.41 \text{ Btu/min}}{1 \text{ hp}} \right) = \mathbf{1.15 \text{ lbm/min}}$$

$$\dot{m}_{\text{methanol}} = \frac{\dot{W}_{\text{methanol}}}{\eta_{\text{th}} \times \text{LHV}_{\text{methanol}} \times \eta_c} = \frac{210.4 \text{ hp}}{(0.40)(8620 \text{ Btu/lbm})(1)} \left(\frac{42.41 \text{ Btu/min}}{1 \text{ hp}} \right) = \mathbf{2.59 \text{ lbm/min}}$$

18-108 A homeowner is to replace the existing natural gas furnace with a wood pellet furnace. The savings due to this replacement are to be determined.

Assumptions **1** Combustion is complete. **2** Combustion efficiency for both furnace is 100 percent.

Analysis The unit price of useful heat supplied by the furnace in the case of natural gas, in \$/MJ, is

$$\text{Unit price of heat (gas)} = \frac{\text{Unit price of gas}}{\eta_{\text{boiler,gas}}} = \frac{\$1.35/\text{therm}}{0.90} \left(\frac{1 \text{ therm}}{105.5 \text{ MJ}} \right) = \$0.01422 / \text{MJ}$$

The unit price of useful heat supplied by the furnace in the case of pellet, in \$/MJ, is

$$\text{Unit price of heat (pellet)} = \frac{\text{Unit price of pellet}}{\eta_{\text{boiler,pellet}} \times \text{HV}} = \frac{\$0.15/\text{kg}}{(0.80)(20 \text{ MJ/kg})} = \$0.009375 / \text{MJ}$$

Using these unit prices, the annual fuel cost in the case of pellet furnace would be

$$\text{Annual pellet cost} = \text{Annual gas cost} \times \frac{\text{Unit price of heat (pellet)}}{\text{Unit price of heat (gas)}} = (\$3000) \frac{\$0.009375 / \text{MJ}}{\$0.01422 / \text{MJ}} = \$1978$$

Therefore, the savings due to this replacement would be

$$\text{Savings} = \text{Annual gas cost} - \text{Annual pellet cost} = \$3000 - \$1978 = \mathbf{\$1022}$$

18-109 Municipal solid waste (MSW) is burned directly in a boiler to generate saturated steam and this steam is run through a turbine to generate power. The amount of steam and electricity generated and the revenue generated by selling the electricity are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis The properties of water at the boiler inlet (state 1), boiler exit and turbine inlet (state 2), and turbine exit (state 3) are obtained from steam tables (Tables A-4 through A-6)

$$\left. \begin{array}{l} T_1 = 20^\circ\text{C} \\ x_1 = 0 \end{array} \right\} h_1 = 83.91 \text{ kJ/kg}$$

$$\left. \begin{array}{l} T_2 = 200^\circ\text{C} \\ x_2 = 1 \end{array} \right\} \begin{array}{l} h_2 = 2792.0 \text{ kJ/kg} \\ s_2 = 6.4302 \text{ kJ/kg} \cdot \text{K} \end{array}$$

$$\left. \begin{array}{l} P_3 = 100 \text{ kPa} \\ s_3 = s_2 \end{array} \right\} h_{3s} = 2328.8 \text{ kJ/kg}$$

The actual enthalpy at the turbine exit is determined from the definition of isentropic efficiency as

$$\eta_T = \frac{h_2 - h_3}{h_2 - h_{3s}} \longrightarrow 0.85 = \frac{2792.0 - h_3}{2792.0 - 2328.8} \longrightarrow h_3 = 2398.3 \text{ kJ/kg}$$

From the definition of the boiler efficiency,

$$\begin{aligned} \eta_{\text{boiler}} &= \frac{Q_{\text{useful}}}{Q_{\text{in}}} = \frac{m_{\text{steam}}(h_2 - h_1)}{m_{\text{MSW}} \times \text{HV}_{\text{MSW}}} \\ 0.75 &= \frac{m_{\text{steam}}(2792.0 - 83.91) \text{ kJ/kg}}{(10,000 \text{ kg})(18,000 \text{ kJ/kg})} \\ m_{\text{steam}} &= \mathbf{49,850 \text{ kg}} \end{aligned}$$

The electric power output from the turbine is

$$W_{\text{electric}} = \eta_{\text{generator}}(h_2 - h_3) = (0.95)(2792.0 - 2398.3) \text{ kJ/kg} \left(\frac{1 \text{ kWh}}{3600 \text{ kJ}} \right) = \mathbf{5180 \text{ kWh}}$$

The revenue that can be generated by selling the electricity is

$$\begin{aligned} \text{Revenue} &= W_{\text{electric}} \times \text{Unit price of electricity} \\ &= (5180 \text{ kWh})(\$0.11/\text{kWh}) \\ &= \mathbf{\$570} \end{aligned}$$

Review Problems

18-110 A solar collector provides the hot water needs of a family. The annual natural gas and cost savings due to solar water heating are to be determined.

Properties The specific heat of water at room temperature is $c_p = 4.18 \text{ kJ/kg}\cdot^\circ\text{C}$.

Analysis The amount of solar water heating during a month period is

$$Q = mc_p(T_1 - T_2) = (6000 \text{ kg/month})(4.18 \text{ kJ/kg}\cdot^\circ\text{C})(60 - 20)^\circ\text{C} = 1.003 \times 10^6 \text{ kJ/month}$$

The amount of gas that would be consumed (or saved) during the 8 month period is

$$\text{Gas savings} = \frac{Q}{\eta_{\text{heater}}} = (8 \text{ months}) \frac{1.003 \times 10^{11} \text{ kJ/month}}{0.88} \left(\frac{1 \text{ therm}}{105,500 \text{ kJ}} \right) = \mathbf{86.44 \text{ therms}}$$

The corresponding cost savings is

$$\begin{aligned} \text{Cost savings} &= \text{Gas savings} \times \text{Unit price of geothermal heat} \\ &= (86.44 \text{ therms})(\$1.35/\text{therm}) \\ &= \mathbf{\$116.7} \end{aligned}$$

18-111 Two concentrating collectors with given characteristics are considered. The solar irradiation rate for collector B to have the same efficiency as collector A and the efficiency change of collector A for a change in irradiation are to be determined.

Analysis (a) The collector efficiency of collector A is determined from

$$\eta_{c,A} = \eta_{ar} - U_A \frac{T_c - T_a}{\text{CR} \times G_A} = 0.88 - (2.5 \text{ W/m}^2 \cdot ^\circ\text{C}) \frac{(145 - 27)^\circ\text{C}}{(7)(600 \text{ W/m}^2)} = 0.8098$$

Using the same relation for collector B at the same collector efficiency, we obtain the necessary solar irradiation rate:

$$\begin{aligned} \eta_{c,B} &= \eta_{ar} - U_B \frac{T_c - T_a}{\text{CR} \times G_B} \\ 0.8098 &= 0.88 - (3.5 \text{ W/m}^2 \cdot ^\circ\text{C}) \frac{(145 - 27)^\circ\text{C}}{(7)G_B} \\ G_B &= \mathbf{840 \text{ W/m}^2} \end{aligned}$$

(b) The collector efficiency of collector A for a solar irradiation of 900 W/m^2 is

$$\eta_{c,A} = \eta_{ar} - U_A \frac{T_c - T_a}{\text{CR} \times G_A} = 0.88 - (2.5 \text{ W/m}^2 \cdot ^\circ\text{C}) \frac{(145 - 27)^\circ\text{C}}{(7)(900 \text{ W/m}^2)} = 0.8332$$

The change in the efficiency of collector A is then

$$\Delta\eta_{c,A} = 0.8332 - 0.8098 = 0.02341 = \mathbf{2.34 \text{ percent}}$$

18-112 The initial cost of a solar power plant is given. The payback period of the investment is to be determined.

Analysis The total cost of this power plant is

$$\text{Plant cost} = \text{Unit cost} \times \dot{W}_{\text{out}} = (\$14,000/\text{kW})(10,000 \text{ kW}) = \$1.400 \times 10^8$$

The annual revenue from selling the electricity produced is

$$\begin{aligned} \text{Annual revenue} &= \dot{W}_{\text{out}} \times \text{Unit price} \times \text{Operating hours} \\ &= (10,000 \text{ kW})(\$0.09/\text{kW})(5000 \text{ h/year}) \\ &= \$4.500 \times 10^6/\text{year} \end{aligned}$$

The simple payback period is then

$$\text{Payback period} = \frac{\text{Plant cost}}{\text{Annual revenue}} = \frac{\$1.400 \times 10^8}{\$4.500 \times 10^6/\text{year}} = \mathbf{31.1 \text{ years}}$$

That is, this plant pays for itself in 31 years, which is not unexpected for solar power plants.

18-113 Two cities are considered for solar power production. The amount of electricity that can be produced in each city are to be determined.

Analysis Using the average daily solar radiation values on a horizontal surface is obtained from [Table 18-3](#) for each city as

$$G_{\text{avg,Fl}} = (17,380 \text{ kJ/m}^2 \cdot \text{day})(365 \text{ days}) = 6.344 \times 10^6 \text{ kJ/m}^2$$

$$G_{\text{avg,At}} = (16,430 \text{ kJ/m}^2 \cdot \text{day})(365 \text{ days}) = 5.997 \times 10^6 \text{ kJ/m}^2$$

Noting that the average thermal efficiency is 18 percent and the total collector area is 30,000 m², the amount of electricity that can be produced in each city would be

$$\text{Amount of electricity (Fl)} = \eta_{\text{th}} A G_{\text{avg,Fl}} = (0.18)(30,000 \text{ m}^2)(6.344 \times 10^6 \text{ kJ/m}^2) \left(\frac{1 \text{ kWh}}{3600 \text{ s}} \right) = \mathbf{9.516 \times 10^7 \text{ kWh}}$$

$$\text{Amount of electricity (At)} = \eta_{\text{th}} A G_{\text{avg,At}} = (0.18)(30,000 \text{ m}^2)(5.997 \times 10^6 \text{ kJ/m}^2) \left(\frac{1 \text{ kWh}}{3600 \text{ s}} \right) = \mathbf{8.995 \times 10^7 \text{ kWh}}$$

18-114 The initial cost of a solar photovoltaic cell system for a house is given. The payback period of this system is to be determined.

Analysis The total cost of the photovoltaic system is

$$\text{System cost} = \text{Unit cost} \times \dot{W}_{\text{out}} = (\$1.3/\text{W})(6000 \text{ W}) = \$7800$$

The current annual electricity cost to the homeowner is

$$\begin{aligned} \text{Annual electricity cost} &= 12 \text{ months/year} \times \text{Monthly bill} \\ &= (12 \text{ months})(\$125/\text{month}) \\ &= \$1500/\text{year} \end{aligned}$$

The homeowner can meet approximately 80 percent of the electricity needs of the house by the solar system.

$$\text{Annual electricity savings} = 0.80 \times \text{Annual electricity cost} = (0.80)(\$1500/\text{year}) = \$1200/\text{year}$$

Then, the simple payback period is determined from

$$\text{Payback period} = \frac{\text{System cost}}{\text{Annual electricity savings}} = \frac{\$7800}{\$1200/\text{year}} = \mathbf{6.5 \text{ years}}$$

That is, this photovoltaic system pays for itself in 6.5 years.

18-115 The ratio of power generated in two locations with different wind velocities is to be determined.

Assumptions Wind flows steadily at the specified speed.

Properties The density of air is same in two locations.

Analysis The wind power potential is expressed for both locations to be

$$\dot{W}_{\text{available1}} = \frac{1}{2} \rho A V_1^3$$

$$\dot{W}_{\text{available2}} = \frac{1}{2} \rho A V_2^3$$

The ratio of power generated from location A and location B is then

$$\frac{\dot{W}_{\text{available1}}}{\dot{W}_{\text{available2}}} = \frac{\frac{1}{2} \rho A V_1^3}{\frac{1}{2} \rho A V_2^3} = \frac{V_1^3}{V_2^3} = \frac{(9 \text{ m/s})^3}{(6 \text{ m/s})^3} = \mathbf{3.375}$$

18-116 An investor to install 40 wind turbines with a specified average wind speed. The payback period of this investment is to be determined.

Assumptions Wind flows steadily at the specified speed.

Properties The density of air is given to be $\rho = 1.18 \text{ kg/m}^3$.

Analysis The blade span area is

$$A = \pi D^2 / 4 = \pi (18 \text{ m})^2 / 4 = 254.5 \text{ m}^2$$

The wind power potential for one turbine is

$$\dot{W}_{\text{available}} = \frac{1}{2} \rho A V_1^3 = \frac{1}{2} (1.18 \text{ kg/m}^3)(254.5 \text{ m}^2)(7.2 \text{ m/s})^3 \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) = 56.04 \text{ kW}$$

The electric power generated is

$$\dot{W}_{\text{electric}} = \eta_{\text{wt,overall}} \dot{W}_{\text{available}} = (0.33)(56.04 \text{ kW}) = 18.49 \text{ kW}$$

The amount of electricity produced is determined from

$$W_{\text{electric}} = \dot{W}_{\text{electric}} \times \text{Operating hours} = (18.49 \text{ kW})(6000 \text{ h}) = 110,940 \text{ kWh}$$

The annual revenue generated by 40 turbines is

$$\begin{aligned} \text{Annual revenue} &= n_{\text{turbine}} \times W_{\text{electric}} \times \text{Unit price of electricity} \\ &= (40)(110,940 \text{ kWh})(\$0.075/\text{kWh}) \\ &= \$332,820/\text{year} \end{aligned}$$

The payback period of this investment is

$$\text{Payback period} = \frac{\text{Total initial cost}}{\text{Annual revenue}} = \frac{\$1,200,000}{\$332,820/\text{year}} = \mathbf{3.61 \text{ years}}$$

18-117 A school is considering installing wind turbines to meet its electricity needs. The required average velocity of wind is to be determined.

Assumptions Wind flows steadily at the specified speed.

Properties The density of air is given to be $\rho = 1.2 \text{ kg/m}^3$.

Analysis The amount of electricity used by the school per year is determine from

$$W_{\text{electric}} = \frac{\text{Annual electricity cost}}{\text{Unit price of electricity}} = \frac{\$23,000/\text{year}}{\$0.11/\text{kWh}} = 209,090 \text{ kWh}$$

The average rate of electrical power is

$$\dot{W}_{\text{electric}} = \frac{W_{\text{electric}}}{\text{Operating hours}} = \frac{110,940 \text{ kWh}}{7500 \text{ h}} = 27.88 \text{ kW}$$

The available wind power is

$$\dot{W}_{\text{available}} = \frac{\dot{W}_{\text{electric}}}{\eta_{\text{wt, overall}}} = \frac{27.88 \text{ kW}}{0.30} = 92.93 \text{ kW}$$

The blade span area is

$$A = \pi D^2 / 4 = \pi (20 \text{ m})^2 / 4 = 314.2 \text{ m}^2$$

The average wind velocity is determined from available wind power relation:

$$\begin{aligned} \dot{W}_{\text{available}} &= \frac{1}{2} \rho A V^3 \\ 92.93 \text{ kW} &= \frac{1}{2} (1.2 \text{ kg/m}^3) (314.2 \text{ m}^2) V^3 \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) \\ V &= \mathbf{7.90 \text{ m/s}} \end{aligned}$$

18-118 A school is considering installing wind turbines to meet its electricity needs. The required average velocity of wind is to be determined.

Assumptions Wind flows steadily at the specified speed.

Properties The density of air is given to be $\rho = 1.2 \text{ kg/m}^3$.

Analysis The amount of electricity used by the school per year is determine from

$$W_{\text{electric}} = \frac{\text{Annual electricity cost}}{\text{Unit price of electricity}} = \frac{\$23,000/\text{year}}{\$0.11/\text{kWh}} = 209,090 \text{ kWh}$$

The average rate of electrical power is

$$\dot{W}_{\text{electric}} = \frac{W_{\text{electric}}}{\text{Operating hours}} = \frac{110,940 \text{ kWh}}{7500 \text{ h}} = 27.88 \text{ kW}$$

The available wind power is

$$\dot{W}_{\text{available}} = \frac{\dot{W}_{\text{electric}}}{\eta_{\text{wt, overall}}} = \frac{27.88 \text{ kW}}{0.30} = 92.93 \text{ kW}$$

The blade span area is

$$A = \pi D^2 / 4 = \pi (30 \text{ m})^2 / 4 = 706.9 \text{ m}^2$$

The average wind velocity is determined from available wind power relation:

$$\begin{aligned} \dot{W}_{\text{available}} &= \frac{1}{2} \rho A V^3 \\ 92.93 \text{ kW} &= \frac{1}{2} (1.2 \text{ kg/m}^3) (706.9 \text{ m}^2) V^3 \left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2} \right) \\ V &= \mathbf{6.03 \text{ m/s}} \end{aligned}$$

18-119 Mechanical energy of a waterfall in a village is to be converted into electricity by a hydraulic turbine. It is to be determined if the proposed turbine can meet electricity needs of the village.

Assumptions 1 The flow is steady. 2 Water level of the waterfall remains constant.

Properties The density of water is taken to be $\rho = 1000 \text{ kg/m}^3 = 1 \text{ kg/L}$.

Analysis The maximum power from the turbine is determined from

$$\begin{aligned}\dot{W}_{\max} &= \dot{m}gH_{\text{gross}} = \rho\dot{V}gH_{\text{gross}} \\ &= (1 \text{ kg/L})(350/60 \text{ L/s})(9.81 \text{ m/s}^2)(80 \text{ m})\left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2}\right) \\ &= 4.578 \text{ kW}\end{aligned}$$

The electric power output is

$$\dot{W}_{\text{electric}} = \eta_{\text{turbine-gen}}\dot{W}_{\max} = (0.82)(4.578 \text{ kW}) = 3.754 \text{ kW}$$

Noting that the turbine will operate nonstop throughout the year, the operating hours in one year is

$$\text{Operating hours} = 365 \times 24 = 8760 \text{ h}$$

The amount of electricity that will be produced per year by the turbine is

$$W_{\text{electric, produced}} = \dot{W}_{\text{electric}} \times \text{Operating hours} = (3.754 \text{ kW})(8760 \text{ h}) = \mathbf{32,885 \text{ kWh}}$$

The current amount of electricity used by the village is

$$W_{\text{electric, consumed}} = \frac{\text{Annual cost of electricity}}{\text{Unit price of electricity}} = \frac{\$4600}{\$0.12/\text{kWh}} = \mathbf{38,333 \text{ kWh}}$$

Therefore, the proposed turbine cannot meet entire electricity needs of the village. However, this may still be a good option as the turbine can meet 86 percent of the electricity needs.

18-120 An investor is to build a hydroelectric power plant. It is to be determined if the plant can pay for itself in 5 years.

Assumptions **1** The flow is steady. **2** Water levels at the reservoir and the discharge site remain constant.

Properties The density of water is taken to be $\rho = 1000 \text{ kg/m}^3 = 1 \text{ kg/L}$.

Analysis The maximum power for one turbine is determined from

$$\begin{aligned}\dot{W}_{\max} &= \dot{m}gH_{\text{gross}} = \rho\dot{V}gH_{\text{gross}} \\ &= (1 \text{ kg/L})(565 \text{ L/s})(9.81 \text{ m/s}^2)(90 \text{ m})\left(\frac{1 \text{ kJ/kg}}{1000 \text{ m}^2/\text{s}^2}\right) \\ &= 498.8 \text{ kW}\end{aligned}$$

The electric power output is

$$\dot{W}_{\text{electric}} = \eta_{\text{plant}}\dot{W}_{\max} = (0.88)(498.8 \text{ kW}) = 439.0 \text{ kW}$$

Noting that the plant operates 8200 h a year, the amount of electricity produced per year by one turbine is

$$W_{\text{electric}} = \dot{W}_{\text{electric}} \times \text{Operating hours} = (439.0 \text{ kW})(8200 \text{ h/year}) = 3,600,000 \text{ kWh/year}$$

Noting that the operating and maintenance expenses of the plant are \$750,000/year, the revenue generated by 10 such turbines is

$$\begin{aligned}\text{Revenue} &= (n_{\text{turbine}} \times W_{\text{electric}} \times \text{Unit price of electricity}) - \text{O \& M Cost} \\ &= [(10)(3,600,000 \text{ kWh/year})(\$0.105/\text{kWh/year})] - \$750,000 \\ &= \mathbf{\$3,030,000\text{year}}\end{aligned}$$

The payback period of this investment is then

$$\text{Payback period} = \frac{\text{Total plant cost}}{\text{Annual revenue}} = \frac{\$24,000,000}{\$3,030,000/\text{year}} = \mathbf{7.92 \text{ years}}$$

This payback period does not satisfy the investor's criterion of 5 years.

18-121 Geothermal water is flashed into a lower pressure in a flash chamber. The temperature and the fractions of liquid and vapor phases after the flashing process are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis The enthalpy of geothermal water at the flash chamber inlet is (Table A-4)

$$\left. \begin{array}{l} T_1 = 210^\circ\text{C} \\ x_1 = 0 \end{array} \right\} h_1 = 897.61 \text{ kJ/kg}$$

A flash chamber is a throttling device across which the enthalpy remains constant. Therefore, the properties at the chamber outlet are (Table A-5)

$$\left. \begin{array}{l} P_2 = 600 \text{ kPa} \\ h_2 = h_1 = 897.61 \text{ kJ/kg} \end{array} \right\} \left. \begin{array}{l} T_2 = \mathbf{158.8^\circ\text{C}} \\ x_2 = \frac{h_2 - h_f}{h_{fg}} = \frac{897.61 - 670.38}{2085.8} = 0.1089 \end{array} \right\}$$

The mass fractions of vapor and liquid phases are

$$\text{mf}_{\text{vapor}} = x_2 = \mathbf{0.1089}$$

$$\text{mf}_{\text{liquid}} = (1 - x_2) = 1 - 0.1089 = \mathbf{0.8911}$$

18-122 The vapor resulting from the flashing process is routed to a steam turbine to produce power. The power output from the turbine is to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis The enthalpy of geothermal water at the flash chamber inlet is (Table A-4)

$$\left. \begin{array}{l} T_1 = 210^\circ\text{C} \\ x_1 = 0 \end{array} \right\} h_1 = 897.61 \text{ kJ/kg}$$

A flash chamber is a throttling device across which the enthalpy remains constant. Therefore, the properties at the chamber outlet are (Table A-5)

$$\left. \begin{array}{l} P_2 = 600 \text{ kPa} \\ h_2 = h_1 = 897.61 \text{ kJ/kg} \end{array} \right\} \left. \begin{array}{l} T_2 = 158.8^\circ\text{C} \\ x_2 = \frac{h_2 - h_f}{h_{fg}} = \frac{897.61 - 670.38}{2085.8} = 0.1089 \end{array} \right\}$$

The mass flow rate of steam through the turbine is

$$\dot{m}_3 = x_2 \dot{m}_1 = (0.1089)(50 \text{ kg/s}) = 5.447 \text{ kg/s}$$

The properties of steam at the turbine inlet and exit are (Table A-5)

$$\left. \begin{array}{l} P_3 = 600 \text{ kPa} \\ x_3 = 1 \end{array} \right\} \left. \begin{array}{l} h_3 = 2756.2 \text{ kJ/kg} \\ s_3 = 6.7593 \text{ kJ/kg} \cdot \text{K} \end{array} \right\}$$

$$\left. \begin{array}{l} P_4 = 20 \text{ kPa} \\ s_4 = s_3 \end{array} \right\} h_{4s} = 2226.4 \text{ kJ/kg}$$

The power output from the turbine is

$$\dot{W}_{\text{T,out}} = \eta_T \dot{m}_3 (h_3 - h_{4s}) = (0.88)(5.447 \text{ kg/s})(2756.2 - 2226.4) \text{ kJ/kg} = \mathbf{2539 \text{ kW}}$$

18-123 A single-flash geothermal power plant uses geothermal liquid water as the heat source, and produces power. The thermal efficiency, the second-law efficiency, and the total rate of exergy destroyed in the plant are to be determined.

Assumptions 1 Steady operating conditions exist. 2 Kinetic and potential energy changes are negligible.

Analysis The properties of geothermal water at the inlet of the plant and at the dead state are obtained from steam tables to be

$$T_1 = 150^\circ\text{C, liquid} \longrightarrow h_1 = 632.18 \text{ kJ/kg, } s_1 = 1.8418 \text{ kJ/kg}\cdot\text{K}$$

$$T_0 = 25^\circ\text{C, } P_0 = 1 \text{ atm} \longrightarrow h_0 = 104.92 \text{ kJ/kg, } s_0 = 0.3672 \text{ kJ/kg}\cdot\text{K}$$

The energy of geothermal water may be taken to be maximum heat that can be extracted from the geothermal water, and this may be expressed as the enthalpy difference between the state of geothermal water and dead state:

$$\dot{E}_{\text{in}} = \dot{m}(h_1 - h_0) = (420 \text{ kg/s})[(632.18 - 104.92) \text{ kJ/kg}] = 221,449 \text{ kW}$$

The exergy of geothermal water is

$$\begin{aligned} \dot{X}_{\text{in}} &= \dot{m}[(h_1 - h_0) - T_0(s_1 - s_0)] \\ &= (420 \text{ kg/s})[(632.18 - 104.92) \text{ kJ/kg} - (25 + 273 \text{ K})(1.8418 - 0.3672) \text{ kJ/kg}\cdot\text{K}] \\ &= 36,888 \text{ kW} \end{aligned}$$

The thermal efficiency of the power plant is

$$\eta_{\text{th}} = \frac{\dot{W}_{\text{net,out}}}{\dot{E}_{\text{in}}} = \frac{15,800 \text{ kW}}{221,449 \text{ kW}} = 0.07135 = \mathbf{7.14\%}$$

The exergy efficiency of the plant is the ratio of power produced to the exergy input (or expended) to the plant:

$$\eta_{\text{II}} = \frac{\dot{W}_{\text{net,out}}}{\dot{X}_{\text{in}}} = \frac{15,800 \text{ kW}}{36,888 \text{ kW}} = 0.4283 = \mathbf{42.8\%}$$

The exergy destroyed in this power plant is determined from an exergy balance on the entire power plant to be

$$\begin{aligned} \dot{X}_{\text{in}} - \dot{W}_{\text{net,out}} - \dot{X}_{\text{dest}} &= 0 \\ 36,888 - 15,800 - \dot{X}_{\text{dest}} &= 0 \\ \dot{X}_{\text{dest}} &= \mathbf{21,088 \text{ kW}} \end{aligned}$$

18-124 The higher heating value of biogas with a given composition is to be determined.

Properties The molar masses of C, H₂, and O₂ are 12 kg/kmol, 2 kg/kmol, and 32 kg/kmol, respectively (Table A-1).

Analysis The mole fractions of CH₄ and CO₂ are equal to their volume fractions:

$$y_{\text{CH}_4} = 0.65$$

$$y_{\text{CO}_2} = 0.35$$

We consider 100 kmol of biogas mixture. In this mixture, there are 65 kmol of CH₄ and 35 kmol of CO₂. The mass of CH₄ and CO₂ are

$$m_{\text{CH}_4} = N_{\text{CH}_4} M_{\text{CH}_4} = (65 \text{ kmol})(16 \text{ kg}) = 1040 \text{ kg}$$

$$m_{\text{CO}_2} = N_{\text{CO}_2} M_{\text{CO}_2} = (35 \text{ kmol})(44 \text{ kg}) = 1540 \text{ kg}$$

The total mass of the mixture is

$$m_{\text{total}} = m_{\text{CH}_4} + m_{\text{CO}_2} = 1040 + 1540 = 2580 \text{ kg}$$

The mass fraction of CH₄ is

$$\text{mf}_{\text{CH}_4} = \frac{m_{\text{CH}_4}}{m_{\text{total}}} = \frac{1040 \text{ kg}}{2580 \text{ kg}} = 0.4031$$

The heating value of CO₂ is zero. Therefore, the higher heating value of biogas is

$$\text{HHV}_{\text{biogas}} = \text{mf}_{\text{CH}_4} \times \text{HHV}_{\text{CH}_4} = (0.4031)(55,200 \text{ kJ/kg}) = \mathbf{22,250 \text{ kJ/kg}}$$

FE Exam Problems

18-125 Which renewable energy sources are only used for electricity generation?

- (a) Wind and solar (b) Hydro and solar (c) Solar and geothermal (d) Wind and hydro
 (e) Hydro and geothermal

Answer: (d) Wind and hydro

18-126 Which renewable energy source should not be considered as the manifestation of solar energy in different forms?

- (a) Wind (b) Hydro (c) Ocean wave (d) Biomass (e) Geothermal

Answer: (e) Geothermal

18-127 Solar radiation is incident on a flat-plate collector at a rate of 450 W/m^2 . The product of transmissivity and absorptivity is $\tau\alpha = 0.85$, and the heat loss coefficient of the collector is $4.5 \text{ W/m}^2\cdot^\circ\text{C}$. The ambient air temperature is 10°C . The collector temperature at which the collector efficiency is zero is

- (a) 95°C (b) 104°C (c) 112°C (d) 87°C (e) 73°C

Answer: (a) 95°C

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
G=450 [W/m^2]
TauAlpha=0.85
U=4.5 [W/m^2-C]
T_a=10 [C]
eta_c=0
eta_c=TauAlpha-U*(T_c-T_a)/G
```

18-128 Solar radiation is incident on a flat-plate collector at a rate of 600 W/m^2 . The glazing has a transmissivity of 0.85 and the absorptivity of absorber plate is 0.92. The heat loss coefficient of the collector is $3.0 \text{ W/m}^2\cdot^\circ\text{C}$. The maximum efficiency of this collector is

- (a) 92% (b) 85% (c) 78% (d) 73% (e) 66%

Answer: (c) 78%

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
G=600 [W/m^2]
Tau=0.85
Alpha=0.92
U=3.0 [W/m^2-C]
eta_c_max=Tau*Alpha
```

18-129 The efficiency of a solar collector is given by $\eta_c = \tau\alpha - U \frac{T_c - T_a}{G}$. If the collector efficiency is plotted against the term $(T_c - T_a)/G$, a straight line is obtained. The slope of this line is equal to

- (a) U (b) $-U$ (c) $\tau\alpha$ (d) $-\tau\alpha$ (e) U/G

Answer: (b) $-U$

18-130 A solar-power-tower plant produces 450 kW of power when solar radiation is incident at a rate of 1050 W/m^2 . If the efficiency of this solar plant is 17 percent, the total collector area receiving solar radiation is

- (a) 1750 m^2 (b) 2090 m^2 (c) 2520 m^2 (d) 3230 m^2 (e) 3660 m^2

Answer: (c) 2520 m^2

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
W_dot=450E3 [W]
G=1050 [W/m^2]
eta_th=0.17
eta_th=W_dot/(A_c*G)
```

18-131 In a solar pond, the water temperature is 40°C near the surface and 90°C near the bottom of the pond. The maximum thermal efficiency a solar pond power plant can have is

- (a) 13.8% (b) 17.5% (c) 25.7% (d) 32.4% (e) 55.5%

Answer: (a) 13.8%

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
T_L=40 [C]
T_H=90 [C]
eta_th_max=1-(T_L+273)/(T_H+273)
```

18-132 In a solar cell, the load voltage is 0.5 V and the load current density is determined to be 80 A/m². If the solar irradiation is 650 W/m², the cell efficiency is

- (a) 4.7% (b) 6.2% (c) 7.8% (d) 9.1% (e) 14.2%

Answer: (b) 6.2%

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
V=0.5 [V]
J_L=80 [A/m^2]
G=650 [W/m^2]
eta_cell=(J_L*V)/G
```

18-133 The power potential of a wind turbine at a wind speed of 5 m/s is 50 kW. The power potential of the same turbine at a velocity of 8 m/s is

- (a) 80 kW (b) 128 kW (c) 180 kW (d) 205 kW (e) 242 kW

Answer: (d) 205 kW

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
W_dot_1=50 [kW]
V1=5 [m/s]
V2=8 [m/s]
W_dot_2=W_dot_1*(V2^3/V1^3)
```

18-134 Wind is blowing through a turbine at a velocity of 7 m/s. The turbine blade diameter is 25 m and the density of air is 1.15 kg/m^3 . The power potential of the turbine is

- (a) 180 kW (b) 153 kW (c) 131 kW (d) 116 kW (e) 97 kW

Answer: (e) 97 kW

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
V=7 [m/s]
D=25 [m]
rho=1.15 [kg/m^3]
A=pi*D^2/4
W_dot_available=1/2*rho*A*V^3*Convert(W, kW)
```

18-135 The power potential of a wind turbine at a wind speed of 5 m/s is 100 kW. The blade diameter of this turbine is 40 m. The power potential of a similar turbine with a blade diameter of 60 m at the same velocity is

- (a) 150 kW (b) 225 kW (c) 266 kW (d) 338 kW (e) 390 kW

Answer: (b) 225 kW

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
V=5 [m/s]
W_dot_1=100 [kW]
D1=40 [m]
D2=60 [m]
W_dot_2=W_dot_1*(D2^2/D1^2)
```

18-136 Wind is blowing through a turbine at a velocity of 9 m/s. The turbine blade diameter is 35 m. The air is at 95 kPa and 20°C. If the power output from the turbine is 115 kW, the efficiency of the turbine is

- (a) 29% (b) 32% (c) 35% (d) 38% (e) 42%

Answer: (a) 29%

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
V=9 [m/s]
D=35 [m]
P=95 [kPa]
T=(20+273) [K]
W_dot=115 [kW]
R=0.287 [kJ/kg-K]
rho=P/(R*T)
A=pi*D^2/4
W_dot_available=1/2*rho*A*V^3*Convert(W, kW)
eta_wt=W_dot/W_dot_available
```

18-137 A turbine is placed at the bottom of a 70-m-high water body. Water flows through the turbine at a rate of 15 m³/s. The power potential of the turbine is

- (a) 10.3 MW (b) 8.8 MW (c) 7.6 MW (d) 7.1 MW (e) 5.9 MW

Answer (a) 10.3 MW

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
H=70 [m]
V_dot=15 [m^3/s]
g=9.81 [m/s^2]
rho=1000 [kg/m^3]
W_dot_ideal=rho*g*H*V_dot*Convert(W, kW)
```

18-138 The efficiency of a hydraulic turbine-generator unit is specified to be 85 percent. If the generator efficiency is 96 percent, the turbine efficiency is

- (a) 0.816 (b) 0.850 (c) 0.862 (d) 0.885 (e) 0.960

Answer (d) 0.885

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
eta_turbine_gen=0.85
eta_gen=0.96
eta_turbine=eta_turbine_gen/eta_gen
```

18-139 A hydraulic turbine is used to generate power by using the water in a dam. The elevation difference between the free surfaces upstream and downstream of the dam is 120 m. The water is supplied to the turbine at a rate of 150 kg/s. If the shaft power output from the turbine is 155 kW, the efficiency of the turbine is

- (a) 0.77 (b) 0.80 (c) 0.82 (d) 0.85 (e) 0.88

Answer (e) 0.88

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
h=120 [m]
m_dot=150 [kg/s]
W_dot_shaft=155 [kW]
g=9.81 [m/s^2]
DELTAE_dot=m_dot*g*h*Convert(W, kW)
eta_turbine=W_dot_shaft/DELTAE_dot
```

18-140 The maximum thermal efficiency of a power plant using a geothermal source at 180°C in an environment at 25°C is

- (a) 43.1% (b) 34.2% (c) 19.5% (d) 86.1% (e) 12.7%

Answer: (b) 34.2%

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
T_geo=180 [C]
T0=25 [C]
eta_th_max=1-(T0+273)/(T_geo+273)
```

18-141 Geothermal liquid water is available at a site at 150°C at a rate of 10 kg/s in an environment at 20°C. The maximum amount of power that can be produced from this site is

- (a) 606 kW (b) 692 kW (c) 740 kW (d) 883 kW (e) 955 kW

Answer: (e) 955 kW

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
T_geo=150 [C]
x_geo=0

s0=entropy(Fluid$, T=T0, x=0)
X_dot_geo=m_dot*(h_geo-h0-(T0+273)*(s_geo-s0))
W_dot_max=X_dot_geo
```

18-142 A binary geothermal power plant produces 5 MW power using a geothermal resource at 175°C at a rate of 110 kg/s. If the temperature of geothermal water is decreased to 90°C in the heat exchanger after giving its heat to binary fluid, the thermal efficiency of the binary cycle is

- (a) 7.5% (b) 16.3% (c) 14.4% (d) 12.5% (e) 9.7%

Answer: (d) 12.5%

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
W_dot=5000 [kW]
T_geo_1=175 [C]
T_geo_2=90 [C]
m_dot=110 [kg/s]
Fluid$='Steam_iapws'
h_geo_1=enthalpy(Fluid$, T=T_geo_1, x=0)
h_geo_2=enthalpy(Fluid$, T=T_geo_2, x=0)
Q_dot_in=m_dot*(h_geo_1-h_geo_2)
eta_th=W_dot/Q_dot_in

18-143 A certain biogas consists of 75 percent methane (CH₄) and 25 percent carbon dioxide (CO₂) by volume. If the higher heating value of methane is 55,200 kJ/kg, the higher heating value of this biogas is

- (a) 25,100 kJ/kg (b) 28,800 kJ/kg (c) 33,900 kJ/kg (d) 41,400 kJ/kg
(e) 55,200 kJ/kg

Answer: (b) 28,800 kJ/kg

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
y_CH4=0.75
y_CO2=0.25
HHV_CH4=55200 [kJ/kg]
MM_CH4=16 [kg/kmol]
MM_CO2=44 [kg/kmol]
"Consider 100 kmol of mixture"
N_total=100 [kmol]
N_CH4=y_CH4*N_total
N_CO2=y_CO2*N_total
m_CH4=N_CH4*MM_CH4
m_CO2=N_CO2*MM_CO2
m_total=m_CH4+m_CO2
mf_CH4=m_CH4/m_total
mf_CO2=m_CO2/m_total
HHV_biogas=mf_CH4*HHV_CH4
```

18-144 Consider 100 kg of sugar beet roots whose sugar content represents 15 percent of total mass. The sugar is converted into ethanol through the reaction $C_6H_{12}O_6 \rightarrow 2 C_2H_5OH + 2 CO_2$. The amount of ethanol produced is

- (a) 15 kg (b) 13 kg (c) 9.8 kg (d) 7.7 kg (e) 5.5 kg

Answer: (d) 7.7 kg

Solution Solved by EES Software. Solutions can be verified by copying-and-pasting the following lines on a blank EES screen. (Similar problems and their solutions can be obtained easily by modifying numerical values).

```
m_beet=100 [kg]
mf_sugar=0.15
"C6H12O6 = 2 C2H5OH + 2 CO2"
MM_C6H12O6=180 [kg/kmol]
MM_C2H5OH=46 [kg/kmol]
m_sugar=mf_sugar*m_beet
m_ethanol/m_sugar=2*MM_C2H5OH/MM_C6H12O6
m_ethanol=m_sugar*m_ethanol/m_sugar
```
